CONTENTS

PREFACE

The importance of discrete and combinatorial mathematics has increased dramatically within the last few decades. This second edition has been written to update all content and to broaden the coverage. We have been gratified by the success of the first edition of the *Handbook*. We hope that the many readers who have asked for a second edition will find it worth the wait.

The purpose of the *Handbook of Discrete and Combinatorial Mathematics* is to provide a comprehensive reference volume for computer scientists, engineers, mathematicians, as well as students, physical and social scientists, and reference librarians, who need information about discrete and combinatorial mathematics.

This first edition of this book was the first resource that presented such information in a ready-reference form designed for all those who use aspects of this subject in their work or studies. This second edition is a major revision of the first edition. It includes extensive additions and updates, summarized later in this preface. The scope of this handbook includes the many areas generally considered to be parts of discrete mathematics, focusing on the information considered essential to its application in computer science, engineering, and other disciplines. Some of the fundamental topic areas covered in this edition include:

logic and set theory
enumeration
integer sequences
recurrence relations
generating functions
number theory
abstract algebra
linear algebra
discrete probability theory
data mining
discrete bioinformatics
graph theory
trees
network flows
combinatorial designs
computational geometry
coding theory
cryptography
discrete optimization
automata theory
data structures and algorithms

Format

The material in the *Handbook* is presented so that key information can be located and used quickly and easily. Each chapter includes a glossary that provides succinct definitions of the most important terms from that chapter. Individual topics are covered in sections and subsections within chapters, each of which is organized into clearly identifiable parts: definitions, facts, and examples. Lists of facts include:

- information about how material is used and why it is important
- historical information
- key theorems
- the latest results
- the status of open questions

- tables of numerical values, generally not easily computed
- summary tables
- key algorithms in simple pseudocode
- information about algorithms, such as their complexity
- major applications
- pointers to additional resources, both websites and printed material.

Facts are presented concisely and are listed so that they can be easily found and understood. Cross-references linking portions of the *Handbook* are also provided. Readers who wish to study a topic further can consult the resources listed.

The material in the *Handbook* has been chosen for inclusion primarily because it is important and useful. Additional material has been added to ensure comprehensiveness so that readers encountering new terminology and concepts from discrete mathematics in their explorations will be able to get help from this book.

Examples are provided to illustrate some of the key definitions, facts, and algorithms. Some curious and entertaining facts and puzzles that some readers may find intriguing are also included. Readers will also find an extensive collection of biographies after the main chapters, highlighting the lives of many important contributors to discrete mathematics.

Each chapter of the book includes a list of references divided into a list of printed resources and a list of relevant websites.

How This Book Was Developed

The organization and structure of the first edition of this *Handbook* were developed by a team that included the chief editor, three associate editors, a project editor, and the editor from CRC Press. This team put together a proposed table of contents which was then analyzed by members of a group of advisory editors, each an expert in one or more aspects of discrete mathematics. These advisory editors suggested changes, including the coverage of additional important topics. Once the table of contents was fully developed, the individual sections of the book were prepared by a group of more than 70 contributors from industry and academia who understand how this material is used and why it is important. Contributors worked under the direction of the associate editors and chief editor, with these editors ensuring consistency of style as well as clarity and comprehensiveness in the presentation of material. Material was carefully reviewed by authors and our team of editors to ensure accuracy and consistency of style.

For the second edition, a new team was assembled. The first goal of this team was to put together a new table of contents. This involved identifying opportunities for new chapters and new sections to broaden the scope and appeal of the second edition. With the help of previous and new contributors, additional material was developed and existing material was updated and expanded, following the style and maintaining, or improving, the presentation in the first edition.

Changes in the Second Edition

The development of the second edition of this book was a major effort, extending over many years. Since the first edition appeared in 1999, many new discoveries have been made and new areas have grown in importance. Important changes include:

- an increase from 17 to 20 chapters and over 360 additional pages
- new chapters on discrete bioinformatics and data mining
- individual chapters on coding theory and on cryptography with expanded coverage (previously covered in a single chapter)
- new sections on many topics, including

  Algebraic Number Theory
  Singular Value Decomposition
  Probabilistic Method
  Expander Graphs
  Combinatorial Auctions
  Tabu Search
  Classical Cryptography
  Cryptographic Mechanisms
  Cryptographic Applications
  Classification
  Outlier Analysis
  Phylogenetic Trees
  RNA Folding
  Neural Codes
  Elliptic Curves
  Hidden Markov Models
  Perfect Graphs
  Small-World Networks
  Very Large-Scale Neighborhood Search
  Quantum Error-Correcting Codes
  Cryptographic Hashing Functions
  Modern Private Key Cryptography
  Association Methods
  Clustering
  Sequence Alignment
  Discrete-Time Dynamical Systems
  Food Webs and Competition Graphs
  Genome Assembly

- thousands of updates and additions to existing sections, with major changes or new subsections including

  Primes Numbers
  Cyclic Codes
  Partitions
  Factorization
  Expander Graphs
  Simulation
  Location Theory
  Combinatorial Matrix Theory
  Public Key Cryptography
  Asymptotics of Sequences
  Distance, Connectivity, Traversability, and Matching
  Graph Colorings, Labelings, and Related Parameters
  Communication Networks
  Difficult Routing and Assignment Problems

- more than 30 new biographies
- hundreds of new web resources, which have been accessed to verify their availability in mid-2017

Acknowledgments

First and foremost, we thank Bob Ross, the CRC editor for this book, for his support and his encouragement in completing this *Handbook*. We would also like to thank Bob Stern, our previous editor, for initiating the project of updating the *Handbook* and for supporting us patiently over many years. We would also like to thank Wayne Yuhasz, our original CRC editor, who commissioned the first edition. Thanks also go to the staff at CRC who helped with the production.

We would also like to thank the many people who were involved with this project. First, we would like to thank the team of advisory editors who helped make this reference

relevant, useful, unique, and up-to-date. We want to thank our many contributors for their wonderful contributions and to several who helped edit individual chapters. With the passing of time, some of our advisory editors and contributors are no longer with us. We fondly remember and appreciate these colleagues and friends. (We have used the symbol ⊛ to designate these individuals.)

Finally, as Chief Editor, I would like to express my gratitude to my two associate editors for this edition. Without either of them this new edition would not have been possible. Both were essential in our quest to bring this *Handbook* up to date and to extend its scope. Douglas Shier confronted every problem that got in our way and found a workable solution. He kept the progress on this project going with his commitment and his abilities. Wayne Goddard used his masterful LaTeX skills to overcome all the typesetting challenges that confronted us as we migrated to a new typesetting environment.

FOUNDATIONS

INTRODUCTION

This chapter covers material usually referred to as the foundations of mathematics, including logic, sets, and functions. In addition to covering these foundational areas, this chapter includes material that shows how these topics are applied to discrete mathematics, computer science, and electrical engineering. For example, this chapter covers methods of proof, program verification, and fuzzy reasoning.

GLOSSARY

action: a literal or a print command in a production system.

aleph-null: the cardinality $\aleph_0$ of the set $\mathcal{N}$ of natural numbers.

AND: the logical operator for conjunction, also written $\wedge$.

antecedent: in a conditional proposition $p \rightarrow q$ ("if p then q"), the proposition p ("if-clause") that precedes the arrow.

antichain: a subset of a poset in which no two elements are comparable.

antisymmetric: the property of a binary relation R that if aRb and bRa, then $a = b$.

argument form: a sequence of statement forms, each called a *premise* of the argument, followed by a statement form called a *conclusion* of the argument.

assertion (or ***program assertion***): a program comment specifying some conditions on the values of the computational variables; these conditions are supposed to hold whenever program flow reaches the location of the assertion.

asymmetric: the property of a binary relation R that if aRb, then $b\not R a$.

asymptotic: A function f is asymptotic to a function g, written $f(x) \sim g(x)$, if $f(x) \neq 0$ for sufficiently large x and $\lim_{x\rightarrow\infty} \frac{g(x)}{f(x)} = 1$.

atom (or ***atomic formula***): a simplest formula of predicate logic.

atomic formula: See *atom*.

atomic proposition: a proposition that cannot be analyzed into smaller parts and logical operations.

automated reasoning: the process of proving theorems using a computer program that can draw conclusions that follow logically from a set of given facts.

axiom: a statement that is assumed to be true; a postulate.

axiom of choice: the assertion that given any nonempty collection $\mathcal{A}$ of pairwise disjoint sets, there is a set that consists of exactly one element from each of the sets in $\mathcal{A}$.

axiom (or ***semantic axiom***): a rule for a programming language construct prescribing the change of values of computational variables when an instruction of that construct-type is executed.

basis step: a proof of the basis premise (first case) in a proof by mathematical induction.

big-oh notation: f is $O(g)$, written $f = O(g)$, if there are constants C and k such that $|f(x)| \leq C|g(x)|$ for all $x > k$.

bijection (or ***bijective function***): a function that is one-to-one and onto.

bijective function: See *bijection*.

binary relation (from a set A to a set B): any subset of $A \times B$.

binary relation (on a set A): a binary relation from A to A; i.e., a subset of $A \times A$.

body (of a clause $A_1, \ldots, A_n \leftarrow B_1, \ldots, B_m$ in a logic program): the literals $B_1, \ldots, B_m$ after $\leftarrow$.

cardinal number (or ***cardinality***) of a set: for a finite set, the number of elements; for an infinite set, the order of infinity. The cardinal number of S is written $|S|$.

cardinality: See *cardinal number*.

Cartesian product (of sets A and B): the set $A \times B$ of ordered pairs (a, b) with $a \in A$ and $b \in B$ (more generally, the ***iterated Cartesian product*** $A_1 \times A_2 \times \cdots \times A_n$ is the set of ordered n-tuples $(a_1, a_2, \ldots, a_n)$, with $a_i \in A_i$ for each i).

ceiling (of x): the smallest integer that is greater than or equal to x, written $\lceil x \rceil$.

chain: a subset of a poset in which every pair of elements are comparable.

characteristic function (of a set S): the function from S to $\{0, 1\}$ whose value at x is 1 if $x \in S$ and 0 if $x \notin S$.

clause (in a logic program): a closed formula of the form $\forall x_1 \ldots \forall x_s (A_1 \vee \cdots \vee A_n \leftarrow B_1 \wedge \cdots \wedge B_m)$.

closed formula: for a function value $f(x)$, an algebraic expression in x.

closure (of a relation R with respect to a property $\mathcal{P}$): the relation S, if it exists, that has property $\mathcal{P}$ and contains R, such that S is a subset of every relation that has property $\mathcal{P}$ and contains R.

codomain (of a function): the set in which the function values occur.

comparable (elements in a poset): elements that are related by the partial order relation.

complement (of a relation): given a relation R, the relation $\overline{R}$ where $a\overline{R}b$ if and only if $a \not R b$.

complement (of a set): given a set A in a "universal" domain U, the set $\overline{A}$ of objects in U that are not in A.

complement operator: a function $[0, 1] \rightarrow [0, 1]$ used for complementing fuzzy sets.

complete: the property of a set of axioms that it is possible to prove all true statements.

complex number: a number of the form $a + bi$, where a and b are real numbers, and $i^2 = -1$; the set of all complex numbers is denoted $\mathcal{C}$.

composite key: given an n-ary relation R on $A_1 \times A_2 \times \cdots \times A_n$, a product of domains $A_{i_1} \times A_{i_2} \times \cdots \times A_{i_m}$ such that for each m-tuple $(a_{i_1}, a_{i_2}, \ldots, a_{i_m}) \in A_{i_1} \times A_{i_2} \times \cdots \times A_{i_m}$, there is at most one n-tuple in R that matches $(a_{i_1}, a_{i_2}, \ldots, a_{i_m})$ in coordinates $i_1, i_2, \ldots, i_m$.

composition (of relations): for R a relation from A to B and S a relation from B to C, the relation $S \circ R$ from A to C such that $a(S \circ R)c$ if and only if there exists $b \in B$ such that aRb and bSc.

composition (of functions): the function $f \circ g$ whose value at x is $f(g(x))$.

compound proposition: a proposition built up from atomic propositions and logical connectives.

computer-assisted proof: a proof that relies on checking the validity of a large number of cases using a special purpose computer program.

conclusion (of an argument form): the last statement of an argument form.

conclusion (of a proof): the last proposition of a proof; the objective of the proof is demonstrating that the conclusion follows from the premises.

condition: the disjunction $A_1 \vee \cdots \vee A_n$ of atomic formulas.

conditional statement: the compound proposition $p \to q$ ("if p then q") that is true except when p is true and q is false.

conjunction: the compound proposition $p \wedge \mathrm{q}$ ("p and q") that is true only when p and q are both true.

conjunctive normal form: for a proposition in the variables $p_1, p_2, \ldots, p_n$, an equivalent proposition that is the conjunction of disjunctions, with each disjunction of the form $x_{k_1} \vee x_{k_2} \vee \cdots \vee x_{k_m}$, where x_{k_j} is either p_{k_j} or $\neg p_{k_j}$.

consequent: in a conditional proposition $p \to q$ ("if p then q") the proposition q ("then-clause") that follows the arrow.

consistent: the property of a set of axioms that no contradiction can be deduced from the axioms.

construct (or ***program construct***): the general form of a programming instruction such as an assignment, a conditional, or a while-loop.

continuum hypothesis: the assertion that the cardinal number of the real numbers is the smallest cardinal number greater than the cardinal number of the natural numbers.

contradiction: a self-contradictory proposition, one that is always false.

contradiction (in an indirect proof): the negation of a premise.

contrapositive (of the conditional proposition $p \to q$): the conditional proposition $\neg q \to \neg p$.

converse (of the conditional proposition $p \to q$): the conditional proposition $q \to p$.

converse relation: another name for the inverse relation.

corollary: a theorem that is derived as an easy consequence of another theorem.

correct conclusion: the conclusion of a valid proof, when all the premises are true.

countable set: a set that is finite or denumerable.

counterexample: a case that makes a statement false.

definite clause: clause with at most one atom in its head.

denumerable set: a set that can be placed in one-to-one correspondence with the natural numbers.

diagonalization proof: any proof that involves something analogous to the diagonal of a list of sequences.

difference: a binary relation $R - S$ such that $a(R-S)b$ if and only if aRb is true and aSb is false.

difference (of sets): the set $A - B$ of objects in A that are not in B.

direct proof: a proof of $p \to q$ that assumes p and shows that q must follow.

disjoint (pair of sets): two sets with no members in common.

disjunction: the statement $p \vee q$ ("p or q") that is true when at least one of the two propositions p and q is true; also called *inclusive or*.

disjunctive normal form: for a proposition in the variables $p_1, p_2, \ldots, p_n$, an equivalent proposition that is the disjunction of conjunctions, with each conjunction of the form $x_{k_1} \wedge x_{k_2} \wedge \cdots \wedge x_{k_m}$, where x_{k_j} is either p_{k_j} or $\neg p_{k_j}$.

disproof: a proof that a statement is false.

divisibility lattice: the lattice consisting of the positive integers under the relation of divisibility.

domain (of a function): the set on which a function acts.

element (of a set): member of the set; the notation $a \in A$ means that a is an element of A.

elementary projection function: the function $\pi_i \colon X_1 \times \cdots \times X_n \to X_i$ such that $\pi(x_1, \ldots, x_n) = x_i$.

empty set: the set with no elements, written $\emptyset$ or $\{\ \}$.

epimorphism: an onto function.

equality (of sets): the property that two sets have the same elements.

equivalence class: given an equivalence relation on a set A and $a \in A$, the subset of A consisting of all elements related to a.

equivalence relation: a binary relation that is reflexive, symmetric, and transitive.

equivalent propositions: two compound propositions (on the same simple variables) with the same truth table.

existential quantifier: the quantifier $\exists x$, read "there is an x".

existentially quantified predicate: a statement $(\exists x)P(x)$ that there exists a value of x such that $P(x)$ is true.

exponential function: any function of the form b^x, b a positive constant, $b \neq 1$.

fact set: the set of ground atomic formulas.

factorial (function): the function $n!$ whose value on the argument n is the product $1 \cdot 2 \cdot 3 \ldots n$; that is, $n! = 1 \cdot 2 \cdot 3 \ldots n$.

finite: the property of a set that it is either empty or else can be put in a one-to-one correspondence with a set $\{1, 2, 3, \ldots, n\}$ for some positive integer n.

first-order logic: See *predicate calculus*.

floor (of x): the greatest integer less than or equal to x, written $\lfloor x \rfloor$.

formula: a logical expression constructed from atoms with conjunctions, disjunctions, and negations, possibly with some logical quantifiers.

full conjunctive normal form: conjunctive normal form where each disjunction is a disjunction of all variables or their negations.

full disjunctive normal form: disjunctive normal form where each conjunction is a conjunction of all variables or their negations.

fully parenthesized proposition: any proposition that can be obtained using the following recursive definition: (1) each variable is fully parenthesized; (2) if P and Q are fully parenthesized, so are $(\neg P)$, $(P \wedge Q)$, $(P \vee Q)$, $(P \rightarrow Q)$, and $(P \leftrightarrow Q)$.

function $f\colon A \rightarrow B$: a rule that assigns to every object a in the domain set A exactly one object $f(a)$ in the codomain set B.

functionally complete set: a set of logical connectives from which all other connectives can be derived by composition.

fuzzy logic: a system of logic in which each statement has a truth value in the interval $[0, 1]$.

fuzzy set: a set in which each element is associated with a number in the interval $[0, 1]$ that measures its degree of membership.

generalized continuum hypothesis: the assertion that for every infinite set S there is no cardinal number greater than $|S|$ and less than $|\mathcal{P}(S)|$.

goal: a clause with an empty head.

graph (of a function): given a function $f\colon A \rightarrow B$, the set $\{(a, b) \mid b = f(a)\} \subseteq A \times B$.

greatest lower bound (of a subset of a poset): an element of the poset that is a lower bound of the subset and is greater than or equal to every other lower bound of the subset.

ground formula: a formula without any variables.

halting function: the function that maps computer programs to the set $\{0, 1\}$, with value 1 if the program always halts, regardless of input, and 0 otherwise.

Hasse diagram: a directed graph that represents a poset.

head (of a clause $A_1, \ldots, A_n \leftarrow B_1, \ldots, B_m$): the literals $A_1, \ldots, A_n$ before $\leftarrow$.

identity function (on a set): given a set A, the function from A to itself whose value at x is x.

image set (of a function): the set of function values as x ranges over all objects of the domain.

implication: formally, the relation $P \Rightarrow Q$ that a proposition Q is true whenever proposition P is true; informally, a synonym for the conditional statement $p \rightarrow q$.

incomparable: two elements in a poset that are not related by the partial order relation.

independent: the property of a set of axioms that none of the axioms can be deduced from the other axioms.

indirect proof: a proof of $p \rightarrow q$ that assumes $\neg q$ is true and proves that $\neg p$ is true.

induced partition (on a set under an equivalence relation): the collection of equivalence classes under the relation.

induction: See *mathematical induction*.

induction hypothesis: in a mathematical induction proof, the statement $P(x_k)$ in the induction step.

induction step: in a mathematical induction proof, a proof of the induction premise “if $P(x_k)$ is true, then $P(x_{k+1})$ is true”.

inductive proof: See *mathematical induction*.

infinite (set): a set that is not finite.

injection (or ***injective function***): a one-to-one function.

instance (of a formula): formula obtained using a substitution.

instantiation: substitution of concrete values for the free variables of a statement or sequence of statements; an instance of a production rule.

integer: a whole number, possibly zero or negative; i.e., one of the elements in the set $\mathcal{Z} = \{\ldots, -2, -1, 0, 1, 2, \ldots\}$.

intersection: the set $A \cap B$ of objects common to both sets A and B.

intersection relation: for binary relations R and S on A, the relation $R \cap S$ where $a(R \cap S)b$ if and only if aRb and aSb.

interval (in a poset): given $a \leq b$ in a poset, a subset of the poset consisting of all elements x such that $a \leq x \leq b$.

inverse function: for a one-to-one, onto function $f\colon X \to Y$, the function $f^{-1}\colon Y \to X$ whose value at $y \in Y$ is the unique $x \in X$ such that $f(x) = y$.

inverse image (under $f\colon X \to Y$ of a subset $T \subseteq Y$): the subset $\{x \in X \mid f(x) \in T\}$, written $f^{-1}(T)$.

inverse relation: for a binary relation R from A to B, the relation R^{-1} from B to A where $bR^{-1}a$ if and only if aRb.

invertible (function): a one-to-one and onto function; a function that has an inverse.

irrational number: a real number that is not rational.

irreflexive: the property of a binary relation R on A that $a \not R a$, for all $a \in A$.

lattice: a poset in which every pair of elements has both a least upper bound and a greatest lower bound.

least upper bound (of a subset of a poset): an element of the poset that is an upper bound of the subset and is less than or equal to every other upper bound of the subset.

lemma: a theorem that is an intermediate step in the proof of a more important theorem.

linearly ordered: the property of a poset that every pair of elements are comparable, also called *totally ordered*.

literal: an atom or its negation.

little-oh notation: f is $o(g)$ if $\lim_{x \to \infty} \left| \frac{f(x)}{g(x)} \right| = 0$.

logarithmic function: a function $\log_b x$ (b a positive constant, $b \neq 1$) defined by the rule $\log_b x = y$ if and only if $b^y = x$.

logic program: a finite sequence of definite clauses.

logically equivalent propositions: compound propositions that involve the same variables and have the same truth table.

logically implies: A compound proposition P logically implies a compound proposition Q if Q is true whenever P is true.

loop invariant: an expression that specifies the circumstance under which the loop body will be executed again.

lower bound (for a subset of a poset): an element of the poset that is less than or equal to every element of the subset.

mathematical induction: a method of proving that every item of a sequence of propositions such as $P(n_0), P(n_0+1), P(n_0+2), \ldots$ is true by showing: (1) $P(n_0)$ is true, and (2) for all $n \geq n_0$, $P(n) \rightarrow P(n+1)$ is true.

maximal element (in a poset): an element that has no element greater than it.

maximum element (in a poset): an element greater than or equal to every element.

membership function (in fuzzy logic): a function from elements of a set to [0,1].

membership table (for a set expression): a table used to calculate whether an object lies in the set described by the expression, based on its membership in the sets mentioned by the expression.

minimal element (in a poset): an element that has no element smaller than it.

minimum element (in a poset): an element less than or equal to every element.

monomorphism: a one-to-one function.

multi-valued logic: a logic system with a set of more than two truth values.

multiset: an extension of the set concept, in which each element may occur arbitrarily many times.

mutually disjoint (family of sets): See *pairwise disjoint*.

n-ary predicate: a statement involving n variables.

n-ary relation: any subset of $A_1 \times A_2 \times \cdots \times A_n$.

naive set theory: set theory where any collection of objects can be considered to be a valid set, with paradoxes ignored.

NAND: the logical connective "not and".

natural number: a nonnegative integer (or "counting" number); i.e., an element of $\mathcal{N} = \{0, 1, 2, 3, \ldots\}$. *Note*: Sometimes 0 is not regarded as a natural number.

negation: the statement $\neg p$ ("not p") that is true if and only if p is not true.

NOP: pronounced "no-op", a program instruction that does nothing to alter the values of computational variables or the order of execution.

NOR: the logical connective "not or".

NOT: the logical connective meaning "not", used in place of $\neg$.

null set: the set with no elements, written $\emptyset$ or $\{\ \}$.

omega notation: f is $\Omega(g)$ if there are constants C and k such that $|g(x)| \leq C|f(x)|$ for all $x > k$.

one-to-one (function): a function $f\colon X \rightarrow Y$ that assigns distinct elements of the codomain to distinct elements of the domain; thus, if $x_1 \neq x_2$, then $f(x_1) \neq f(x_2)$.

onto (function): a function $f\colon X \rightarrow Y$ whose image equals its codomain; i.e., for every $y \in Y$, there is an $x \in X$ such that $f(x) = y$.

OR: the logical operator for disjunction, also written $\vee$.

pairwise disjoint: the property of a family of sets that each two distinct sets in the family have empty intersection; also called *mutually disjoint*.

paradox: a statement that contradicts itself.

partial function: a function $f\colon X \to Y$ that assigns a well-defined object in Y to some (but not necessarily all) the elements of its domain X.

partial order: a binary relation that is reflexive, antisymmetric, and transitive.

partially ordered set: a set with a partial order relation defined on it.

partition (of a set S): a pairwise disjoint family $\mathcal{P} = \{A_i\}$ of nonempty subsets of S whose union is S.

Peano definition: a recursive description of the natural numbers that uses the concept of successor.

Polish prefix notation: the style of writing compound propositions in prefix notation where sometimes the usual operand symbols are replaced as follows: N for $\neg$, K for $\wedge$, A for $\vee$, C for $\to$, E for $\leftrightarrow$.

poset: a partially ordered set.

postcondition: an assertion that appears immediately after the executable portion of a program fragment or of a subprogram.

postfix notation: the style of writing compound logical propositions where operators are written to the right of the operands.

power (of a relation): for a relation R on A, the relation R^n on A where $R^0 = I$, $R^1 = R$, and $R^n = R^{n-1} \circ R$ for all $n > 1$.

power set: given a set A, the set $\mathcal{P}(A)$ of all subsets of A.

precondition: an assertion that appears immediately before the executable portion of a program fragment or of a subprogram.

predicate: a statement involving one or more variables that range over various domains.

predicate calculus: the symbolic study of quantified predicate statements.

prefix notation: the style of writing compound logical propositions where operators are written to the left of the operands.

premise: a proposition taken as the foundation of a proof, from which the conclusion is to be derived.

prenex normal form: the form of a well-formed formula in which every quantifier occurs at the beginning and the scope is whatever follows the quantifiers.

preorder: a binary relation that is reflexive and transitive.

primary key: for an n-ary relation on $A_1, A_2, \ldots, A_n$, a coordinate domain A_j such that for each $x \in A_j$ there is at most one n-tuple in the relation whose jth coordinate is x.

production rule: a formula of the form $C_1, \ldots, C_n \to A_1, \ldots, A_m$ where each C_i is a condition and each A_i is an action.

production system: a set of production rules and a fact set.

program construct: See *construct*.

program fragment: any sequence of program code, from a single instruction to an entire program.

program semantics (or ***semantics***): the meaning of an instruction or of a program fragment; i.e., the effect of its execution on the computational variables.

projection function: a function defined on a set of n-tuples that selects the elements in certain coordinate positions.

proof (of a conclusion from a set of premises): a sequence of statements (called steps) terminating in the conclusion, such that each step is either a premise or follows from previous steps by a valid argument.

proof by contradiction: a proof that assumes the negation of the statement to be proved and shows that this leads to a contradiction.

proof done by hand: a proof done by a human without the use of a computer.

proper subset: given a set S, a subset T of S such that S contains at least one element not in T.

proposition: a declarative sentence or statement that is unambiguously either true or false.

propositional calculus: the symbolic study of propositions.

range (of a function): the image set of a function; sometimes used as synonym for codomain.

rational number: the ratio $\frac{a}{b}$ of two integers such that $b \neq 0$; the set of all rational numbers is denoted $\mathcal{Q}$.

real number: a number expressible as a finite (i.e., terminating) or infinite decimal; the set of all real numbers is denoted $\mathcal{R}$.

recursive definition (of a function with domain $\mathcal{N}$): a set of initial values and a rule for computing $f(n)$ in terms of values $f(k)$ for $k < n$.

recursive definition (of a set S): a form of specification of membership of S, in which some *basis* elements are named individually, and in which a computable rule is given to construct each other element in a finite number of steps.

refinement of a partition: given a partition $\mathcal{P}_1 = \{A_j\}$ on a set S, a partition $\mathcal{P}_2 = \{B_i\}$ on the same set S such that every $B_i \in \mathcal{P}_2$ is a subset of some $A_j \in \mathcal{P}_1$.

reflexive: the property of a binary relation R that aRa.

relation (from set A to set B): a binary relation from A to B.

relation (on a set A): a binary relation from A to A.

restriction (of a function): given $f\colon X \to Y$ and a subset $S \subseteq X$, the function $f|S$ with domain S and codomain Y whose rule is the same as that of f.

reverse Polish notation: postfix notation.

rule of inference: a valid argument form.

satisfiable compound proposition: a compound proposition that is true for at least one assignment of truth variables to its variables.

scope (of a quantifier): the predicate to which the quantifier applies.

semantic axiom: See *axiom*.

semantics: See *program semantics*.

sentence: a well-formed formula with no free variables.

sequence (in a set): a list of objects from a set S, with repetitions allowed; that is, a function $f\colon \mathcal{N} \to S$ (an infinite sequence, often written $a_0, a_1, a_2, \ldots$) or a function $f\colon \{1, 2, \ldots, n\} \to S$ (a finite sequence, often written $a_1, a_2, \ldots, a_n$).

set: a well-defined collection of objects.

singleton: a set with one element.

specification: in program correctness, a precondition and a postcondition.

statement form: a declarative sentence containing some variables and logical symbols which becomes a proposition if concrete values are substituted for all free variables.

string: a finite sequence in a set S, usually written so that consecutive entries are juxtaposed (i.e., written with no punctuation or extra space between them).

strongly correct code: code whose execution terminates in a computational state satisfying the postcondition, whenever the precondition holds before execution.

subset (of a set S): any set T of objects that are also elements of S, written $T \subseteq S$.

substitution: a set of pairs of variables and terms.

surjection or (***surjective function***): an onto function.

symmetric: the property of a binary relation R that if aRb then bRa.

symmetric difference (of relations): for relations R and S on A, the relation $R \oplus S$ where $a(R \oplus S)b$ if and only if exactly one of the following is true: aRb, aSb.

symmetric difference (of sets): for sets A and B, the set $A \oplus B$ containing each object that is an element of A or an element of B, but not an element of both.

system of distinct representatives: given sets $A_1, A_2, \ldots, A_n$ (some of which may be equal), a set $\{a_1, a_2, \ldots, a_n\}$ of n distinct elements with $a_i \in A_i$ for $i = 1, 2, \ldots, n$.

tautology: a compound proposition whose form makes it always true, regardless of the truth values of its atomic parts.

term (in a domain): either a fixed element of a domain S or an S-valued variable.

theorem: a statement derived as the conclusion of a valid proof from axioms and definitions.

theta notation: f is $\Theta(g)$, written $f = \Theta(g)$, if there are positive constants C_1, C_2, and k such that $C_1|g(x)| \leq |f(x)| \leq C_2|g(x)|$ for all $x > k$.

totally ordered: the property of a poset that every pair of elements are comparable; also called *linearly ordered*.

transitive: the property of a binary relation R that if aRb and bRc, then aRc.

transitive closure: for a relation R on A, the smallest transitive relation containing R.

transitive reduction (of a relation): a relation with the same transitive closure as the original relation and with a minimum number of ordered pairs.

truth table: for a compound proposition, a table that gives the truth value of the proposition for each possible combination of truth values of the atomic variables in the proposition.

two-valued logic: a logic system where each statement has exactly one of the two values: true or false.

union: the set $A \cup B$ of objects in one or both of the sets A and B.

union relation: for R and S binary relations on A, the relation $R \cup S$ where $a(R \cup S)b$ if and only if aRb or aSb.

universal domain: the collection of all possible objects in the context of the immediate discussion.

universal quantifier: the quantifier $\forall x$, read "for all x" or "for every x".

universally quantified predicate: a statement $(\forall x)P(x)$ that $P(x)$ is true for every x in its universe of discourse.

universe of discourse: the range of possible values of a variable, within the context of the immediate discussion.

upper bound (for a subset of a poset): an element of the poset that is greater than or equal to every element of the subset.

valid argument form: an argument form such that in any instantiation where all the premises are true, the conclusion is also true.

Venn diagram: a figure composed of possibly overlapping circles or ellipses, used to picture membership in various combinations of the sets.

verification (of a program): a formal argument for the correctness of a program with respect to its specifications.

weakly correct code: code whose execution results in a computational state satisfying the postcondition, whenever the precondition holds before execution and the execution terminates.

well-formed formula (***wff***): a proposition or predicate with quantifiers that bind one or more of its variables.

well-ordered: the property of a set that every nonempty subset has a minimum element.

well-ordering principle: the axiom that every nonempty subset of integers, each greater than a fixed integer, contains a smallest element.

XOR: the logical connective "not or".

Zermelo-Fraenkel axioms: a set of axioms for set theory.

zero-order logic: propositional calculus.

1.1 PROPOSITIONAL AND PREDICATE LOGIC

Logic is the basis for distinguishing what may be correctly inferred from a given collection of facts. Propositional logic, where there are no quantifiers (so quantifiers range over nothing) is called zero-order logic. Predicate logic, where quantifiers range over members of a universe, is called first-order logic. Higher-order logic includes second-order logic (where quantifiers can range over relations over the universe), third-order logic (where quantifiers can range over relations over relations), and so on. Logic has many applications in computer science, including circuit design (§5.8.3) and verification of computer program correctness (§1.6). This section defines the meaning of the symbolism and various logical properties that are usually used without explicit mention. See [FlPa95], [Me09], and [Mo76].

Here, only two-valued logic is studied; i.e., each statement is either true or false. Multi-valued logic, in which statements have one of more than two values, is discussed in §1.7.2.

1.1.1 PROPOSITIONS AND LOGICAL OPERATIONS

Definitions:

A ***truth value*** is either true or false, abbreviated T and F, respectively.

A ***proposition*** (in a natural language such as English) is a declarative sentence that has a well-defined truth value.

A ***propositional variable*** is a mathematical variable, often denoted by p, q, or r, that represents a proposition.

Propositional logic (or ***propositional calculus*** or ***zero-order logic***) is the study of logical propositions and their combinations using logical connectives.

A ***logical connective*** is an operation used to build more complicated logical expressions out of simpler propositions, whose truth values depend only on the truth values of the simpler propositions.

A proposition is ***atomic*** or ***simple*** if it cannot be syntactically analyzed into smaller parts; it is usually represented by a single logical variable.

A proposition is ***compound*** if it contains one or more logical connectives.

A ***truth table*** is a table that prescribes the defining rule for a logical operation. That is, for each combination of truth values of the operands, the table gives the truth value of the expression formed by the operation and operands.

The unary connective ***negation*** (denoted by $\neg$) is defined by the following truth table:

p	$\neg p$
T	F
F	T

Note: The negation $\neg p$ is also written p', $\overline{p}$, or $\sim p$.

The common binary connectives are:

$p \wedge q$	***conjunction***	*p and q*
$p \vee q$	***disjunction***	*p or q*
$p \rightarrow q$	***conditional***	*if p then q*
$p \leftrightarrow q$	***biconditional***	*p if and only if q*
$p \oplus q$	***exclusive or***	*p xor q*
$p \downarrow q$	***not or***	*p nor q*
$p \mid q$ or $p \uparrow q$	***not and***	*p nand q*

The connective $\mid$ is called the *Sheffer stroke*. The connective $\downarrow$ is called the *Peirce arrow*.

The values of the compound propositions obtained by using the binary connectives are given in the following table:

p	q	$p \vee q$	$p \wedge q$	$p \rightarrow q$	$p \leftrightarrow q$	$p \oplus q$	$p \downarrow q$	$p \mid q$
T	T	T	T	T	T	F	F	F
T	F	T	F	F	F	T	F	T
F	T	T	F	T	F	T	F	T
F	F	F	F	T	T	F	T	T

In the conditional $p \rightarrow q$, p is the ***antecedent*** and q is the ***consequent***. The conditional $p \rightarrow q$ is often read informally as "p implies q".

Infix notation is the style of writing compound propositions where binary operators are written between the operands and negation is written to the left of its operand.

Prefix notation is the style of writing compound propositions where operators are written to the left of the operands.

Postfix notation (or ***reverse Polish notation***) is the style of writing compound propositions where operators are written to the right of the operands.

Polish notation is the style of writing compound propositions where operators are written using prefix notation and where the usual operand symbols are replaced as follows: N for $\neg$, K for $\wedge$, A for $\vee$, C for $\rightarrow$, E for $\leftrightarrow$. (Jan Łukasiewicz, 1878–1956)

A ***fully parenthesized proposition*** is any proposition that can be obtained using the following recursive definition: (1) each variable is fully parenthesized; (2) if P and Q are fully parenthesized, so are $(\neg P)$, $(P \wedge Q)$, $(P \vee Q)$, $(P \rightarrow Q)$, and $(P \leftrightarrow Q)$.

Facts:

1. The conditional connective $p \rightarrow q$ represents the following English constructs:

- if p then q
- p only if q
- q follows from p
- p is a sufficient condition for q
- q if p
- p implies q
- q whenever p
- q is a necessary condition for p.

2. The biconditional connective $p \leftrightarrow q$ represents the following English constructs:

- p if and only if q (often written p iff q)
- p and q imply each other
- p is a necessary and sufficient condition for q
- p and q are equivalent.

3. In computer programming and circuit design, the following notation for logical operators is used: p AND q for $p \wedge q$, p OR q for $p \vee q$, NOT p for $\neg p$, p XOR q for $p \oplus q$, p NOR q for $p \downarrow q$, p NAND q for $p \mid q$.

4. *Order of operations*: In an unparenthesized compound proposition using only the five standard operators $\neg$, $\wedge$, $\vee$, $\rightarrow$, and $\leftrightarrow$, the following order of precedence is typically used when evaluating a logical expression, at each level of precedence moving from left to right: first $\neg$, then $\wedge$ and $\vee$, then $\rightarrow$, finally $\leftrightarrow$. Parenthesized expressions are evaluated proceeding from the innermost pair of parentheses outward, analogous to the evaluation of an arithmetic expression.

5. It is often preferable to use parentheses to show precedence, except for negation operators, rather than to rely on precedence rules.

6. No parentheses are needed when a compound proposition is written in either prefix or postfix notation. However, parentheses may be necessary when a compound proposition is written in infix notation.

7. The number of nonequivalent logical statements with two variables is 16, because each of the four lines of the truth table has two possible entries, T or F. Here are examples of compound propositions that yield each possible combination of truth values. (**T** represents a tautology and **F** a contradiction. See §1.1.2.)

p	q	**T**	$p \vee q$	$q \rightarrow p$	$p \rightarrow q$	$p \mid q$	p	q	$p \leftrightarrow q$
T	T	T	T	T	T	F	T	T	T
T	F	T	T	T	F	T	T	F	F
F	T	T	T	F	T	T	F	T	F
F	F	T	F	T	T	T	F	F	T

p	q	$p \oplus q$	$\neg q$	$\neg p$	$p \wedge q$	$p \wedge \neg q$	$\neg p \wedge$	$p \downarrow q$	**F**
T	T	F	F	F	T	F	F	F	F
T	F	T	T	F	F	T	F	F	F
F	T	T	F	T	F	F	T	F	F
F	F	F	T	T	F	F	F	T	F

8. The number of different possible logical connectives on n variables is 2^{2^n}, because there are 2^n rows in the truth table.

9. The problem of determining whether a compound proposition is satisfiable, known as the *Propositional Satisfiability Problem* (abbreviated as SAT), is important in many practical applications, such as in circuit design and in artificial intelligence, and it is also important in the study of algorithms.

10. No efficient (polynomial-time) algorithm has been found for solving SAT. Because it is NP-complete (see Section 16.4.1), if a polynomial-time algorithm could be found for solving this problem, the famous P versus NP problem would be solved in the affirmative.

Examples:

1. "1+1 = 3" and "Romulus and Remus founded New York City" are false propositions.

2. "1 + 1 = 2" and "The year 1996 was a leap year" are true propositions.

3. "Go directly to jail" is not a proposition, because it is imperative, not declarative.

4. "$x > 5$" is not a proposition, because its truth value cannot be determined unless the value of x is known.

5. "This sentence is false" is not a proposition, because it cannot be given a truth value without creating a contradiction.

6. In a truth table evaluation of the compound proposition $p \vee (\neg p \wedge q)$ from the innermost parenthetic expression outward, the steps are to evaluate $\neg p$, next $(\neg p \wedge q)$, and then $p \vee (\neg p \wedge q)$:

p	q	$\neg p$	$(\neg p \wedge q)$	$p \vee (\neg p \wedge q)$
T	T	F	F	T
T	F	F	F	T
F	T	T	T	T
F	F	T	F	F

7. The statements in the left column are evaluated using the order of precedence indicated in the fully parenthesized form in the right column:

$$\begin{array}{ll} p \vee q \wedge r & ((p \vee q) \wedge r) \\ p \leftrightarrow q \rightarrow r & (p \leftrightarrow (q \rightarrow r)) \\ \neg q \vee \neg r \rightarrow s \wedge t & (((\neg q) \vee (\neg r)) \rightarrow (s \wedge t)) \end{array}$$

8. The infix statement $p \wedge q$ in prefix notation is $\wedge\, p\, q$, in postfix notation is $p\, q \wedge$, and in Polish notation is $K\, p\, q$.

9. The infix statement $p \rightarrow \neg(q \vee r)$ in prefix notation is $\rightarrow p \neg \vee q\, r$, in postfix notation is $p\, q\, r \vee \neg \rightarrow$, and in Polish notation is $\mathrm{C}\, p\, \mathrm{N}\, \mathrm{A}\, q\, r$.

1.1.2 EQUIVALENCES, IDENTITIES, AND NORMAL FORMS

Definitions:

A ***tautology*** is a compound proposition that is always true, regardless of the truth values of its underlying atomic propositions.

A ***contradiction*** (or ***self-contradiction***) is a compound proposition that is always false, regardless of the truth values of its underlying atomic propositions. (The term self-contradiction is used for such a proposition when discussing indirect mathematical arguments, because "contradiction" has another meaning in that context. See §1.5.)

A ***contingency*** is a compound proposition that is neither a tautology nor a contradiction.

A compound proposition is ***satisfiable*** if there is at least one assignment of truth values for which it is true.

A compound proposition P ***logically implies*** a compound proposition Q, written $P \Rightarrow Q$, if Q is true whenever P is true. In this case, P is ***stronger than*** Q, and Q is ***weaker than*** P.

Compound propositions P and Q are ***logically equivalent***, written $P \equiv Q$, $P \Leftrightarrow Q$, or P iff Q, if they have the same truth values for all possible truth values of their variables.

A logical equivalence that is frequently used is sometimes called a ***logical identity***.

A collection $\mathcal{C}$ of connectives is ***functionally complete*** if every compound proposition is equivalent to a compound proposition constructed using only connectives in $\mathcal{C}$.

A ***disjunctive normal expression*** in the propositions $p_1, p_2, \ldots, p_n$ is a disjunction of one or more propositions, each of the form $x_{k_1} \wedge x_{k_2} \wedge \cdots \wedge x_{k_m}$, where x_{k_j} is either p_{k_j} or $\neg p_{k_j}$.

A ***disjunctive normal form*** (***DNF***) for a proposition P is a disjunctive normal expression that is logically equivalent to P.

A ***conjunctive normal expression*** in the propositions $p_1, p_2, \ldots, p_n$ is a conjunction of one or more compound propositions, each of the form $x_{k_1} \vee x_{k_2} \vee \cdots \vee x_{k_m}$, where x_{k_j} is either p_{k_j} or $\neg p_{k_j}$.

A ***conjunctive normal form*** (***CNF***) for a proposition P is a conjunctive normal expression that is logically equivalent to P.

A compound proposition P using only the connectives $\neg$, $\wedge$, and $\vee$ has a ***logical dual*** (denoted P' or P^d), obtained by interchanging $\wedge$ and $\vee$, and interchanging the constant **T** (true) and the constant **F** (false).

The ***converse*** of the conditional proposition $p \to q$ is the proposition $q \to p$.

The ***contrapositive*** of the conditional proposition $p \to q$ is the proposition $\neg q \to \neg p$.

The ***inverse*** of the conditional proposition $p \to q$ is the proposition $\neg p \to \neg q$.

Facts:

1. $P \Leftrightarrow Q$ is true if and only if $P \Rightarrow Q$ and $Q \Rightarrow P$.

2. $P \Leftrightarrow Q$ is true if and only if $P \leftrightarrow Q$ is a tautology.

3. The following table lists several logical identities.

name	*rule*
Commutative laws	$p \wedge q \Leftrightarrow q \wedge p, \quad p \vee q \Leftrightarrow q \vee p$
Associative laws	$p \wedge (q \wedge r) \Leftrightarrow (p \wedge q) \wedge r, \quad p \vee (q \vee r) \Leftrightarrow (p \vee q) \vee r$
Distributive laws	$p \wedge (q \vee r) \Leftrightarrow (p \wedge q) \vee (p \wedge r)$ $p \vee (q \wedge r) \Leftrightarrow (p \vee q) \wedge (p \vee r)$
DeMorgan's laws	$\neg(p \wedge q) \Leftrightarrow (\neg p) \vee (\neg q), \quad \neg(p \vee q) \Leftrightarrow (\neg p) \wedge (\neg q)$
Excluded middle	$p \vee \neg p \Leftrightarrow \boldsymbol{T}$
Contradiction	$p \wedge \neg p \Leftrightarrow \boldsymbol{F}$
Double negation law	$\neg(\neg p) \Leftrightarrow p$
Contrapositive law	$p \to q \Leftrightarrow \neg q \to \neg p$
Conditional as disjunction	$p \to q \Leftrightarrow \neg p \vee q$
Negation of conditional	$\neg(p \to q) \Leftrightarrow p \wedge \neg q$
Biconditional as implication	$(p \leftrightarrow q) \Leftrightarrow (p \to q) \wedge (q \to p)$
Idempotent laws	$p \wedge p \Leftrightarrow p, \quad p \vee p \Leftrightarrow p$
Absorption laws	$p \wedge (p \vee q) \Leftrightarrow p, \quad p \vee (p \wedge q) \Leftrightarrow p$
Dominance laws	$p \vee \boldsymbol{T} \Leftrightarrow \boldsymbol{T}, \quad p \wedge \boldsymbol{F} \Leftrightarrow \boldsymbol{F}$
Exportation law	$p \to (q \to r) \Leftrightarrow (p \wedge q) \to r$
Identity laws	$p \wedge \boldsymbol{T} \Leftrightarrow p, \quad p \vee \boldsymbol{F} \Leftrightarrow p$

4. There are different ways to establish logical identities (equivalences):

- truth tables (showing that both expressions have the same truth values);
- using known logical identities and equivalences to establish new ones;
- taking the dual of a known identity (Fact 7).

5. Logical identities are used in circuit design to simplify circuits. See §5.8.4.

6. Each of the following sets of connectives is functionally complete:

$$\{\wedge, \vee, \neg\}, \quad \{\wedge, \neg\}, \quad \{\vee, \neg\}, \quad \{\,|\,\}, \quad \{\downarrow\}.$$

However, these sets of connectives are not functionally complete:

$$\{\wedge\}, \quad \{\vee\}, \quad \{\wedge, \vee\}.$$

7. If $P \Leftrightarrow Q$ is a logical identity, then so is $P' \Leftrightarrow Q'$, where P' and Q' are the duals of P and Q, respectively.

8. Every proposition has a disjunctive normal form and a conjunctive normal form, which can be obtained by Algorithms 1 and 2.

```
Algorithm 1: Disjunctive normal form of proposition $P$.
  write the truth table for $P$
  for each line of the truth table on which $P$ is true, form a "line term"
    $x_1 \wedge x_2 \wedge \cdots \wedge x_n$, where $x_i := p_i$ if $p_i$ is true on that line of the truth table
    and $x_i := \neg p_i$ if $p_i$ is false on that line
  form the disjunction of all these line terms
```

```
Algorithm 2: Conjunctive normal form of proposition $P$.
  write the truth table for $P$
  for each line of the truth table on which $P$ is false, form a "line term"
    $x_1 \vee x_2 \vee \cdots \vee x_n$, where $x_i := p_i$ if $p_i$ is false on that line of the truth table
    and $x_i := \neg p_i$ if $p_i$ is true on that line
  form the conjunction of all these line terms
```

Examples:

1. The proposition $p \vee \neg p$ is a tautology (the *law of the excluded middle*).

2. The proposition $p \vee \neg p$ is a self-contradiction.

3. The proposition $(p \vee \neg q) \wedge (q \vee \neg r) \wedge (r \vee \neg p)$ is satisfiable because it is true when p, q, and r are all false. Note, however, that $(p \leftrightarrow q) \wedge (\neg p \leftrightarrow q)$ is unsatisfiable, as it is false for each of the four possible assignments of truth values for p and q.

4. A proof that $p \leftrightarrow q$ is logically equivalent to $(p \wedge q) \vee (\neg p \wedge \neg q)$ can be carried out using a truth table:

p	q	$p \leftrightarrow q$	$\neg p$	$\neg q$	$p \wedge q$	$\neg p \wedge \neg q$	$(p \wedge q) \vee (\neg p \wedge \neg q)$
T	T	T	F	F	T	F	T
T	F	F	F	T	F	F	F
F	T	F	T	F	F	F	F
F	F	T	T	T	F	T	T

Since the third and eighth columns of the truth table are identical, the two statements are equivalent.

5. A proof that $p \leftrightarrow q$ is logically equivalent to $(p \wedge q) \vee (\neg p \wedge \neg q)$ can be given by a series of logical equivalences. Reasons are given at the right.

$$\begin{aligned}
p \leftrightarrow q \quad &\Leftrightarrow (p \rightarrow q) \wedge (q \rightarrow p) && \text{biconditional as implication}\\
&\Leftrightarrow (\neg p \vee q) \wedge (\neg q \vee p) && \text{conditional as disjunction}\\
&\Leftrightarrow [(\neg p \vee q) \wedge \neg q] \vee [(\neg p \vee q) \wedge p] && \text{distributive law}\\
&\Leftrightarrow [(\neg p \wedge \neg q) \vee (q \wedge \neg q)] \vee [(\neg p \wedge p) \vee (q \wedge p)] && \text{distributive law}\\
&\Leftrightarrow [(\neg p \wedge \neg q) \vee \mathbf{F}] \vee [\mathbf{F} \vee (q \wedge p)] && \text{contradiction}\\
&\Leftrightarrow [(\neg p \wedge \neg q) \vee \mathbf{F}] \vee [(q \wedge p) \vee \mathbf{F}] && \text{commutative law}\\
&\Leftrightarrow (\neg p \wedge \neg q) \vee (q \wedge p) && \text{identity law}\\
&\Leftrightarrow (\neg p \wedge \neg q) \vee (p \wedge q) && \text{commutative law}\\
&\Leftrightarrow (p \wedge q) \vee (\neg p \wedge \neg q) && \text{commutative law}
\end{aligned}$$

6. The proposition $p \downarrow q$ is logically equivalent to $\neg(p \vee q)$. Its DNF is $\neg p \wedge \neg q$, and its CNF is $(\neg p \vee \neg q) \wedge (\neg p \vee q) \wedge (p \vee \neg q)$.

7. The proposition $p|q$ is logically equivalent to $\neg(p \wedge q)$. Its DNF is $(p \wedge \neg q) \vee (\neg p \wedge q) \vee (\neg p \wedge \neg q)$, and its CNF is $\neg p \vee \neg q$.

8. The DNF and CNF for Examples 6 and 7 were obtained by using Algorithm 1 and Algorithm 2 to construct the following table of terms:

p	q	$p \downarrow q$	*DNF terms*	*CNF terms*
T	T	F		$\neg p \vee \neg q$
T	F	F		$\neg p \vee q$
F	T	F		$p \vee \neg q$
F	F	T	$\neg p \wedge \neg q$	

p	q	$p \mid q$	*DNF terms*	*CNF terms*
T	T	F		$\neg p \vee \neg q$
T	F	T	$p \wedge \neg q$	
F	T	T	$\neg p \wedge q$	
F	F	T	$\neg p \wedge \neg q$	

9. The dual of $p \wedge (q \vee \neg r)$ is $p \vee (q \wedge \neg r)$.

10. Let S be the proposition in three propositional variables p, q, and r that is true when precisely two of the variables are true. Then the disjunctive normal form for S is

$$(p \wedge q \wedge \neg r) \vee (p \wedge \neg q \wedge r) \vee (\neg p \wedge q \wedge r)$$

and the conjunctive normal form for S is

$$(\neg p \vee \neg q \vee \neg r) \wedge (\neg p \vee q \vee r) \wedge (p \vee \neg q \vee r) \wedge (p \vee q \vee \neg r) \wedge (p \vee q \vee r).$$

1.1.3 PREDICATE LOGIC

Definitions:

A ***predicate*** is a declarative statement with the symbolic form $P(x)$ or $P(x_1, \ldots, x_n)$ about one or more variables x or $x_1, \ldots, x_n$ whose values are unspecified.

Predicate logic (or ***predicate calculus*** or ***first-order logic***) is the study of statements whose variables have quantifiers.

The ***universe of discourse*** (or ***universe*** or ***domain***) of a variable is the set of possible values of the variable in a predicate.

An ***instantiation*** of the predicate $P(x)$ is the result of substituting a fixed constant value c from the domain of x for each free occurrence of x in $P(x)$. This is denoted by $P(c)$.

The ***existential quantification*** of a predicate $P(x)$ whose variable ranges over a domain set D is the proposition $(\exists x \in D)P(x)$ or $(\exists x)P(x)$ that is true if there is at least one c in D such that $P(c)$ is true. The *existential quantifier symbol* $\exists$ is read “there exists” or “there is”.

The ***universal quantification*** of a predicate $P(x)$ whose variable ranges over a domain set D is the proposition $(\forall x \in D)P(x)$ or $(\forall x)P(x)$, which is true if $P(c)$ is true for every element c in D. The *universal quantifier symbol* $\forall$ is read "for all", "for each", or "for every".

The ***unique existential quantification*** of a predicate $P(x)$ whose variable ranges over a domain set D is the proposition $(\exists! x)P(x)$ that is true if $P(c)$ is true for exactly one c in D. The *unique existential quantifier symbol* $\exists!$ is read "there is exactly one".

The ***scope*** of a quantifier is the predicate to which it applies.

A variable x in a predicate $P(x)$ is a ***bound variable*** if it lies inside the scope of an x-quantifier. Otherwise it is a ***free variable***.

A ***well-formed formula*** (***wff***) (or ***statement***) is either a proposition or a predicate with quantifiers that bind one or more of its variables.

A ***sentence*** (***closed wff***) is a well-formed formula with no free variables.

A well-formed formula is in ***prenex normal form*** if all the quantifiers occur at the beginning and the scope is whatever follows the quantifiers.

A well-formed formula is ***atomic*** if it does not contain any logical connectives; otherwise the well-formed formula is ***compound***.

Higher-order logic is the study of statements that allow quantifiers to range over relations over a universe (second-order logic), relations over relations over a universe (third-order logic), etc.

Facts:

1. If a predicate $P(x)$ is atomic, then the scope of $(\forall x)$ in $(\forall x)P(x)$ is implicitly the entire predicate $P(x)$.

2. If a predicate is a compound form, such as $P(x) \wedge Q(x)$, then $(\forall x)[P(x) \wedge Q(x)]$ means that the scope is $P(x) \wedge Q(x)$, whereas $(\forall x)P(x) \wedge Q(x)$ means that the scope is only $P(x)$, in which case the free variable x of the predicate $Q(x)$ has no relationship to the variable x of $P(x)$.

3. Universal statements in predicate logic are analogues of conjunctions in propositional logic. If variable x has domain $D = \{x_1, \ldots, x_n\}$, then $(\forall x \in D)P(x)$ is true if and only if $P(x_1) \wedge \cdots \wedge P(x_n)$ is true.

4. Existential statements in predicate logic are analogues of disjunctions in propositional logic. If variable x has domain $D = \{x_1, \ldots, x_n\}$, then $(\exists x \in D)P(x)$ is true if and only if $P(x_1) \vee \cdots \vee P(x_n)$ is true.

5. Adjacent universal quantifiers [existential quantifiers] can be transposed without changing the meaning of a logical statement:

$$\begin{aligned}(\forall x)(\forall y)P(x,y) &\Leftrightarrow (\forall y)(\forall x)P(x,y)\\ (\exists x)(\exists y)P(x,y) &\Leftrightarrow (\exists y)(\exists x)P(x,y)\end{aligned}$$

6. Transposing adjacent logical quantifiers of different types can change the meaning of a statement. (See Example 4.)

7. *Rules for negations of quantified statements*:

$$\begin{aligned}\neg(\forall x)P(x) &\Leftrightarrow (\exists x)[\neg P(x)]\\ \neg(\exists x)P(x) &\Leftrightarrow (\forall x)[\neg P(x)]\\ \neg(\exists! x)P(x) &\Leftrightarrow \neg(\exists x)P(x) \vee (\exists y)(\exists z)[(y \neq z) \wedge P(y) \wedge P(z)].\end{aligned}$$

8. Every quantified statement is logically equivalent to some statement in prenex normal form.

9. Every statement with a unique existential quantifier is equivalent to a statement that uses only existential and universal quantifiers, according to the rule:

$$(\exists! x)P(x) \Leftrightarrow (\exists x)\big[P(x) \wedge (\forall y)[P(y) \to (x = y)]\big]$$

where $P(y)$ means that y has been substituted for all free occurrences of x in $P(x)$, and where y is a variable that does not occur in $P(x)$.

10. If a statement uses only the connectives $\vee$, $\wedge$, and $\neg$, the following equivalences can be used along with Fact 7 to convert the statement into prenex normal form. The letter A represents a wff without the variable x.

$$\begin{aligned}
(\forall x)P(x) \wedge (\forall x)Q(x) &\Leftrightarrow (\forall x)[P(x) \wedge Q(x)]\\
(\forall x)P(x) \vee (\forall x)Q(x) &\Leftrightarrow (\forall x)(\forall y)[P(x) \vee Q(y)]\\
(\exists x)P(x) \wedge (\exists x)Q(x) &\Leftrightarrow (\exists x)(\exists y)[P(x) \wedge Q(y)]\\
(\exists x)P(x) \vee (\exists x)Q(x) &\Leftrightarrow (\exists x)[P(x) \vee Q(x)]\\
(\forall x)P(x) \wedge (\exists x)Q(x) &\Leftrightarrow (\forall x)(\exists y)[P(x) \wedge Q(y)]\\
(\forall x)P(x) \vee (\exists x)Q(x) &\Leftrightarrow (\forall x)(\exists y)[P(x) \vee Q(y)]\\
A \vee (\forall x)P(x) &\Leftrightarrow (\forall x)[A \vee P(x)]\\
A \vee (\exists x)P(x) &\Leftrightarrow (\exists x)[A \vee P(x)]\\
A \wedge (\forall x)P(x) &\Leftrightarrow (\forall x)[A \wedge P(x)]\\
A \wedge (\exists x)P(x) &\Leftrightarrow (\exists x)[A \wedge P(x)].
\end{aligned}$$

Examples:

1. The statement $(\forall x \in \mathcal{R})(\forall y \in \mathcal{R})\,[x+y = y+x]$ is syntactically a predicate preceded by two universal quantifiers. It asserts the commutative law for the addition of real numbers.

2. The statement $(\forall x)(\exists y)\,[xy = 1]$ expresses the existence of multiplicative inverses for all numbers in whatever domain is under discussion. Thus, it is true for the positive real numbers, but it is false when the domain is the entire set of reals, since zero has no multiplicative inverse.

3. The statement $(\forall x \neq 0)(\exists y)\,[xy = 1]$ asserts the existence of multiplicative inverses for nonzero numbers.

4. $(\forall x)(\exists y)\,[x + y = 0]$ expresses the true proposition that every real number has an additive inverse, but $(\exists y)(\forall x)\,[x+y = 0]$ is the false proposition that there is a “universal additive inverse” that when added to any number always yields the sum 0.

5. In the statement $(\forall x \in \mathcal{R})\,[x+y = y+x]$, the variable x is bound and the variable y is free.

6. “Not all men are mortal” is equivalent to “there exists at least one man who is not mortal”. Also, “there does not exist a cow that is blue” is equivalent to the statement “every cow is a color other than blue”.

7. The statement $(\forall x)\,P(x) \to (\forall x)\,Q(x)$ is not in prenex form. An equivalent prenex form is $(\forall x)(\exists y)\,[P(y) \to Q(x)]$.

8. The following table illustrates the differences in meaning among the four different ways to quantify a predicate with two variables:

statement	*meaning*
$(\exists x)(\exists y)\,[x + y = 0]$	There is a pair of numbers whose sum is zero.
$(\forall x)(\exists y)\,[x + y = 0]$	Every number has an additive inverse.
$(\exists x)(\forall y)\,[x + y = 0]$	There is a universal additive inverse x.
$(\forall x)(\forall y)\,[x + y = 0]$	The sum of every pair of numbers is zero.

9. The statement $(\forall x)(\exists! y)\,[x + y = 0]$ asserts the existence of *unique* additive inverses.

1.2 SET THEORY

Sets are used to group objects and to serve as the basic elements for building more complicated objects and structures. Counting elements in sets is an important part of discrete mathematics. General reference books that cover the material of this section are [Cu16], [FlPa95], [Ha11], and [Ka10].

1.2.1 SETS

Definitions:

A ***set*** is any well-defined collection of objects, each of which is called a ***member*** or an ***element*** of the set. The notation $x \in A$ means that the object x is a member of the set A. The notation $x \notin A$ means that x is not a member of A.

A ***roster*** for a finite set specifies the membership of a set S as a list of its elements within braces, i.e., in the form $S = \{a_1, \ldots, a_n\}$. Order of the list is irrelevant, as is the number of occurrences of an object in the list.

A ***defining predicate*** specifies a set in the form $S = \{x \mid P(x)\}$, where $P(x)$ is a predicate containing the free variable x. This means that S is the set of all objects x (in whatever domain is under discussion) such that $P(x)$ is true.

A ***recursive description*** of a set S gives a roster B of *basic objects* of S and a set of operations for constructing additional objects of S from objects already known to be in S. That is, any object that can be constructed by a finite sequence of applications of the given operations to objects in B is also a member of S. There may also be a list of axioms that specify when two sequences of operations yield the same result.

The set with no elements is called the ***null set*** or the ***empty set***, denoted $\emptyset$ or $\{\ \}$.

A ***singleton*** is a set with one element.

The set $\mathcal{N}$ of ***natural numbers*** is the set $\{0, 1, 2, \ldots\}$. (Sometimes 0 is excluded from the set of natural numbers; when the set of natural numbers is encountered, check to see how it is being defined.)

The set $\mathcal{Z}$ of ***integers*** is the set $\{\ldots, -2, -1, 0, 1, 2, \ldots\}$.

The set $\mathcal{Q}$ of ***rational numbers*** is the set of all fractions $\frac{a}{b}$, where a is any integer and b is any nonzero integer.

The set $\mathcal{R}$ of ***real numbers*** is the set of all numbers that can be written as terminating or nonterminating decimals.

The set $\mathcal{C}$ of ***complex numbers*** is the set of all numbers of the form $a + bi$, where $a, b \in \mathcal{R}$ and $i = \sqrt{-1}$ $(i^2 = -1)$.

Sets A and B are ***equal***, written $A = B$, if they have exactly the same elements:

$$A = B \Leftrightarrow (\forall x)\,\big[(x \in A) \leftrightarrow (x \in B)\big].$$

Set B is a ***subset*** of set A, written $B \subseteq A$ or $A \supseteq B$, if each element of B is an element of A:

$$B \subseteq A \Leftrightarrow (\forall x)\,\big[(x \in B) \rightarrow (x \in A)\big].$$

Set B is a ***proper subset*** of A if B is a subset of A and A contains at least one element not in B. (The notation $B \subset A$ is often used to indicate that B is a proper subset of A, but sometimes it is used to mean an arbitrary subset. Sometimes the proper subset relationship is written $B \subsetneqq A$, to avoid all possible notational ambiguity.)

A set is ***finite*** if it is either empty or else can be put in a one-to-one correspondence with the set $\{1, 2, 3, \ldots, n\}$ for some positive integer n.

A set is ***infinite*** if it is not finite.

The ***cardinality*** $|S|$ of a finite set S is the number of elements in S.

A ***multiset*** is an unordered collection in which elements can occur arbitrarily often, not just once. The number of occurrences of an element is called its ***multiplicity***.

An ***axiom*** (***postulate***) is a statement that is assumed to be true.

A set of axioms is ***consistent*** if no contradiction can be deduced from the axioms.

A set of axioms is ***complete*** if it is possible to prove all true statements.

A set of axioms is ***independent*** if none of the axioms can be deduced from the other axioms.

A ***set paradox*** is a question in the language of set theory that seems to have no unambiguous answer.

Naive set theory is set theory where any collection of objects can be considered to be a valid set, with paradoxes ignored.

Facts:

1. The theory of sets was first developed by Georg Cantor (1845–1918).

2. $A = B$ if and only if $A \subseteq B$ and $B \subseteq A$.

3. $\mathcal{N} \subset \mathcal{Z} \subset \mathcal{Q} \subset \mathcal{R} \subset \mathcal{C}$.

4. Every rational number can be written as a decimal that is either terminating or else repeating (i.e., the same block repeats end-to-end forever).

5. Real numbers can be represented as the points on the number line, and include all rational numbers and all irrational numbers (such as $\sqrt{2}$, π, e, etc.).

6. There is no set of axioms for set theory that is both complete and consistent.

7. Naive set theory ignores paradoxes. To avoid such paradoxes, more axioms are needed.

Examples:

1. The set $\{x \in \mathcal{N} \mid 3 \leq x < 10\}$, described by the defining predicate $3 \leq x < 10$, is equal to the set $\{3, 4, 5, 6, 7, 8, 9\}$, which is described by a roster.

2. If A is the set with two objects, one being the number 5 and the other being the set whose elements are the letters x, y, and z, then $A = \{5, \{x, y, z\}\}$. In this example, $5 \in A$, but $x \notin A$, since x is not either member of A.

3. The set E of even natural numbers can be described recursively as follows:

Basic objects: $0 \in E$,
Recursion rule: if $n \in E$, then $n + 2 \in E$.

4. *The liar's paradox*: A person says "I am lying". Is the person lying or is the person telling the truth? If the person is lying, then "I am lying" is false, and hence the person is telling the truth. If the person is telling the truth, then "I am lying" is true, and the person is lying. This is also called the *paradox of Epimenides*. This paradox also results from considering the statement "This statement is false".

5. *The barber's paradox*: In a small village populated only by men there is exactly one barber. The villagers follow the following rule: the barber shaves a man if and only if the man does not shave himself. Question: does the barber shave himself? If "yes" (i.e., the barber shaves himself), then according to the rule he does not shave himself. If "no" (i.e., the barber does not shave himself), then according to the rule he does shave himself. This paradox illustrates a danger in describing sets by defining predicates.

6. *Russell's paradox*: This paradox, named for the British logician Bertrand Russell (1872–1970), shows that the "set of all sets" is an ill-defined concept. If it really were a set, then it would be an example of a set that is a member of itself. Thus, some "sets" would contain themselves as elements and others would not. Let S be the "set" of "sets that are not elements of themselves"; i.e., $S = \{A \mid A \notin A\}$. Question: is S a member of itself? If "yes", then S is not a member of itself, because of the defining membership criterion. If "no", then S is a member of itself, due to the defining membership criterion. One resolution is that the collection of all sets is not a set. (See Chapter 4 of [MiRo91].)

7. Paradoxes such as those in Example 6 led Alfred North Whitehead (1861–1947) and Bertrand Russell to develop a version of set theory by categorizing sets based on *set types*: $T_0, T_1, \ldots$. The lowest type T_0 consists only of individual elements. For $i > 0$, type T_i consists of sets whose elements come from type T_{i-1}. This forces sets to belong to exactly one type. The expression $A \in A$ is always false. In this situation Russell's paradox cannot happen.

1.2.2 SET OPERATIONS

Definitions:

The ***intersection*** of sets A and B is the set $A \cap B = \{x \mid (x \in A) \wedge (x \in B)\}$. More generally, the intersection of any family of sets is the set of objects that are members of every set in the family. The notation

$$\bigcap_{i \in I} A_i = \{x \mid x \in A_i \ \text{ for all } i \in I\}$$

is used for the intersection of the family of sets A_i indexed by the set I.

Two sets A and B are ***disjoint*** if $A \cap B = \emptyset$.

A collection of sets $\{a_i \mid i \in I\}$ is ***disjoint*** if $\bigcap_{i\in I} A_i = \emptyset$.

A collection of sets is ***pairwise disjoint*** (or ***mutually disjoint***) if every pair of sets in the collection are disjoint.

The ***union*** of sets A and B is the set $A \cup B = \{x \mid (x \in A) \vee (x \in B)\}$. More generally, the union of a family of sets is the set of objects that are members of at least one set in the family. The notation

$$\bigcup_{i\in I} A_i = \{x \mid x \in A_i \text{ for some } i \in I\}$$

is used for the union of the family of sets A_i indexed by the set I.

A ***partition*** of a set S is a pairwise disjoint family $\mathcal{P} = \{A_i\}$ of nonempty subsets whose union is S.

The partition $\mathcal{P}_2 = \{B_i\}$ of a set S is a ***refinement*** of the partition $\mathcal{P}_1 = \{A_j\}$ of the same set if for every subset $B_i \in \mathcal{P}_2$ there is a subset $A_j \in \mathcal{P}_1$ such that $B_i \subseteq A_j$.

The ***complement*** of the set A is the set $\overline{A} = U - A = \{x \mid x \notin A\}$ containing every object not in A, where the context provides that the objects range over some specific universal domain U. (The notation A' or A^c is sometimes used instead of $\overline{A}$.)

The ***set difference*** is the set $A - B = A \cap \overline{B} = \{x \mid (x \in A) \wedge (x \notin B)\}$. The set difference is sometimes written $A \setminus B$.

The ***symmetric difference*** of A and B is the set $A \oplus B = \{x \mid (x \in A - B) \vee (x \in B - A)\}$. This is sometimes written $A \triangle B$.

The ***Cartesian product*** $A \times B$ of two sets A and B is the set $\{(a,b) \mid (a \in A) \wedge (b \in B)\}$, which contains all ordered pairs whose first coordinate is from A and whose second coordinate is from B. The Cartesian product of $A_1, \ldots, A_n$ is the set $A_1 \times A_2 \times \cdots \times A_n = \prod_{i=1}^{n} A_i = \{(a_1, a_2, \ldots, a_n) \mid (\forall i)(a_i \in A_i)\}$, which contains all ordered n-tuples whose ith coordinate is from A_i. The Cartesian product $A \times A \times \cdots \times A$ is also written A^n. If S is any set, the Cartesian product of the collection of sets A_s, where $s \in S$, is the set $\prod_{s\in S} A_s$ of all functions $f\colon S \to \bigcup_{s\in S} A_s$ such that $f(s) \in A_s$ for all $s \in S$.

The ***power set*** of A is the set $\mathcal{P}(A)$ of all subsets of A. The alternative notation 2^A for $\mathcal{P}(A)$ emphasizes the fact that the power set has 2^n elements if A has n elements.

A ***set expression*** is any expression built up from sets and set operations.

A ***set equation*** (or ***set identity***) is an equation whose left side and right side are both set expressions.

A ***system of distinct representatives*** (***SDR***) for a collection of sets $A_1, A_2, \ldots, A_n$ (some of which may be equal) is a set $\{a_1, a_2, \ldots, a_n\}$ of n distinct elements such that $a_i \in A_i$ for $i = 1, 2, \ldots, n$.

A ***Venn diagram*** is a family of n simple closed curves (typically circles or ellipses) arranged in the plane so that all possible intersections of the interiors are nonempty and connected. (John Venn, 1834–1923.)

A Venn diagram is ***simple*** if at most two curves intersect at any point of the plane.

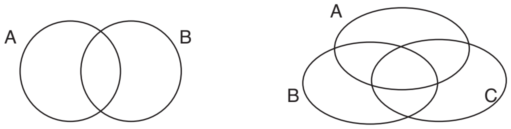
A Venn diagram is ***reducible*** if there is a sequence of curves whose iterative removal leaves a Venn diagram at each step.

A ***membership table*** is a table used to calculate whether an object lies in the set described by a set expression, based on its membership in the sets mentioned by the expression.

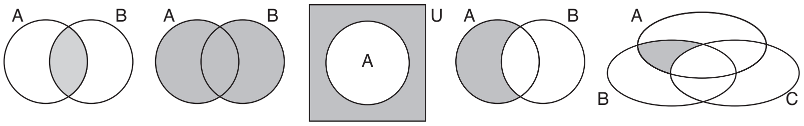
Facts:

1. If a collection of sets is pairwise disjoint, then the collection is disjoint. The converse is false.

2. The following figure illustrates Venn diagrams for two and three sets.



3. The following figure gives the Venn diagrams for sets constructed using various set operations.



A ∩ B (A ∪ B) $\overline{A}$ A - B (A ∩ B) - C

4. Intuition regarding set identities can be gleaned from Venn diagrams, but it can be misleading to use Venn diagrams when proving theorems unless great care is taken to make sure that the diagrams are sufficiently general to illustrate all possible cases.

5. Venn diagrams are often used as an aid to inclusion/exclusion counting. (See §2.4.)

6. Venn gave examples of Venn diagrams with four ellipses and asserted that no Venn diagram could be constructed with five ellipses.

7. Peter Hamburger and Raymond Pippert (1996) constructed a simple, reducible Venn diagram with five congruent ellipses. (Two ellipses are *congruent* if they are the exact same size and shape, and differ only by their placement in the plane.)

8. Many of the logical identities given in §1.1.2 correspond to set identities, given in the following table.

name	*rule*
Commutative laws	$A \cap B = B \cap A, \quad A \cup B = B \cup A$
Associative laws	$A \cap (B \cap C) = (A \cap B) \cap C$
	$A \cup (B \cup C) = (A \cup B) \cup C$
Distributive laws	$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$
	$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$
DeMorgan's laws	$\overline{A \cap B} = \overline{A} \cup \overline{B}, \quad \overline{A \cup B} = \overline{A} \cap \overline{B}$
Complement laws	$A \cap \overline{A} = \emptyset, \quad A \cup \overline{A} = U$
Double complement law	$\overline{\overline{A}} = A$
Idempotent laws	$A \cap A = A, \quad A \cup A = A$
Absorption laws	$A \cap (A \cup B) = A, \quad A \cup (A \cap B) = A$
Dominance laws	$A \cap \emptyset = \emptyset, \quad A \cup U = U$
Identity laws	$A \cup \emptyset = A, \quad A \cap U = A$

9. In a computer, a subset of a relatively small universal domain can be represented by a bit string. Each bit location corresponds to a specific object of the universal domain, and the bit value indicates the presence (1) or absence (0) of that object in the subset.

10. In a computer, a subset of a relatively large ordered datatype or universal domain can be represented by a *binary search tree*. (See §18.2.3.)

11. For any two finite sets A and B, $|A \cup B| = |A| + |B| - |A \cap B|$ (inclusion/exclusion principle). (See §2.4.)

12. Set identities can be proved by any of the following approaches:

- a containment proof: show the left side is a subset of the right side, and the right side is a subset of the left side;
- a membership table: construct the analogue of the truth table for each side of the equation;
- using other set identities.

13. For all sets A, $|A| < |\mathcal{P}(A)|$.

14. *Hall's theorem*: A collection of sets $A_1, A_2, \ldots, A_n$ has a system of distinct representatives if and only if for all $k = 1, \ldots, n$ every collection of k subsets $A_{i_1}, A_{i_2}, \ldots, A_{i_k}$ satisfies $|A_{i_i} \cup A_{i_2} \cup \cdots \cup A_{i_k}| \geq k$.

15. If a collection of sets $A_1, A_2, \ldots, A_n$ has a system of distinct representatives and if an integer m has the property that $|A_i| \geq m$ for each i, then

- if $m \geq n$ there are at least $\frac{m!}{(m-n)!}$ systems of distinct representatives;
- if $m < n$ there are at least $m!$ systems of distinct representatives.

16. Systems of distinct representatives can be phrased in terms of 0-1 matrices and graphs. See §6.6, §8.12.2, and §10.4.3.

Examples:

1. $\{1,2\} \cap \{2,3\} = \{2\}$.

2. The collection of sets $\{1,2\}$, $\{4,5\}$, $\{6,7,8\}$ is pairwise disjoint, and hence disjoint.

3. The collection of sets $\{1,2\}$, $\{2,3\}$, $\{1,3\}$ is disjoint, but not pairwise disjoint.

4. $\{1,2\} \cup \{2,3\} = \{1,2,3\}$.

5. Suppose that for every positive integer n, $[j \textbf{ mod } n] = \{k \in \mathcal{Z} \mid k \textbf{ mod } n = j\}$, for $j = 0, 1, \ldots, n-1$. (See §1.3.1.) Then $\{[0 \textbf{ mod } 3], [1 \textbf{ mod } 3], [2 \textbf{ mod } 3]\}$ is a partition of the integers. Moreover, $\{[0 \textbf{ mod } 6], [1 \textbf{ mod } 6], \ldots, [5 \textbf{ mod } 6]\}$ is a refinement of this partition.

6. Within the context of $\mathcal{Z}$ as universal domain, the complement of the set of positive integers is the set consisting of the negative integers and 0.

7. $\{1,2\} - \{2,3\} = \{1\}$.

8. $\{1,2\} \times \{2,3\} = \{(1,2), (1,3), (2,2), (2,3)\}$.

9. $\mathcal{P}(\{1,2\}) = \{\emptyset, \{1\}, \{2\}, \{1,2\}\}$.

10. If L is a line in the plane, and if for each $x \in L$, C_x is the circle of radius 1 centered at point x, then $\bigcup_{x \in L} C_x$ is an infinite strip of width 2, and $\bigcap_{x \in L} C_x = \emptyset$.

11. The five-fold Cartesian product $\{0,1\}^5$ contains 32 different 5-tuples, including, for instance, $(0,0,1,0,1)$.

12. The set identity $\overline{A \cap B} = \overline{A} \cup \overline{B}$ is verified by the following membership table. Begin by listing the possibilities for elements being in or not being in the sets A and B, using 1 to mean "is an element of" and 0 to mean "is not an element of". Proceed to find the element values for each combination of sets. The two sides of the equation are the same since the columns for $\overline{A \cap B}$ and $\overline{A} \cup \overline{B}$ are identical:

A	B	$A \cap B$	$\overline{A \cap B}$	$\overline{A}$	$\overline{B}$	$\overline{A} \cup \overline{B}$
1	1	1	0	0	0	0
1	0	0	1	0	1	1
0	1	0	1	1	0	1
0	0	0	1	1	1	1

13. The collection of sets $A_1 = \{1,2\}$, $A_2 = \{2,3\}$, $A_3 = \{1,3,4\}$ has systems of distinct representatives, for example $\{1,2,3\}$ and $\{2,3,4\}$.

14. The collection of sets $A_1 = \{1,2\}$, $A_2 = \{1,3\}$, $A_3 = \{2,3\}$, $A_4 = \{1,2,3\}$, $A_5 = \{2,3,4\}$ does not have a system of distinct representatives since $|A_1 \cup A_2 \cup A_3 \cup A_4| < 4$.

1.2.3 INFINITE SETS

Definitions:

The ***Peano definition*** for the natural numbers $\mathcal{N}$:

- 0 is a natural number;
- every natural number n has a successor $s(n)$;
- axioms:
  - ◇ 0 is not the successor of any natural number;
  - ◇ two different natural numbers cannot have the same successor;
  - ◇ if $0 \in T$ and if $(\forall n \in \mathcal{N})\ \big[(n \in T) \rightarrow (s(n) \in T)\big]$, then $T = \mathcal{N}$.

(This axiomatization is named for Giuseppe Peano, 1858–1932.)

A set is ***denumerable*** (or ***countably infinite***) if it can be put in a one-to-one correspondence with the set of natural numbers $\{0,1,2,3,\ldots\}$. (See §1.3.1.)

A ***countable*** set is a set that is either finite or denumerable. All other sets are ***uncountable***.

The ***ordinal numbers*** (or ***ordinals***) are defined recursively as follows:

- the empty set is the ordinal number 0;
- if α is an ordinal number, then so is the *successor* of α, written α^+ or $\alpha+1$, which is the set $\alpha \cup \{\alpha\}$;
- if β is any set of ordinals closed under the successor operation, then β is an ordinal, called a *limit ordinal*.

The ordinal α is said to be ***less than*** the ordinal β, written $\alpha < \beta$, if $\alpha \subseteq \beta$ (which is equivalent to $\alpha \in \beta$).

The ***sum*** of ordinals α and β, written $\alpha + \beta$, is the ordinal corresponding to the well-ordered set given by all the elements of α in order, followed by all the elements of β (viewed as being disjoint from α) in order. (See Fact 26 and §1.4.3.)

The ***product*** of ordinals α and β, written $\alpha \cdot \beta$, is the ordinal equal to the Cartesian product $\alpha \times \beta$ with ordering $(a_1, b_1) < (a_2, b_2)$ whenever $b_1 < b_2$, or $b_1 = b_2$ and $a_1 < a_2$ (this is reverse lexicographic order).

Two sets have the ***same cardinality*** (or are ***equinumerous***) if they can be put into one-to-one correspondence (§1.3.1). When the equivalence relation "equinumerous" is used on all sets (§1.4.2), the sets in each equivalence class have the same ***cardinal number***. The cardinal number of a set A is written $|A|$. It can also be regarded as the smallest ordinal number among all those ordinal numbers with the same cardinality.

An ***order relation*** can be defined on cardinal numbers of sets by the rule $|A| \leq B$ if there is a one-to-one function $f\colon A \rightarrow B$. If $|A| \leq |B|$ and $|A| \neq |B|$, write $|A| < |B|$.

The ***sum*** of cardinal numbers $\mathbf{a}$ and $\mathbf{b}$, written $\mathbf{a}+\mathbf{b}$, is the cardinal number of the union of two disjoint sets A and B such that $|A| = \mathbf{a}$ and $|B| = \mathbf{b}$.

The ***product*** of cardinal numbers $\mathbf{a}$ and $\mathbf{b}$, written $\mathbf{ab}$, is the cardinal number of the Cartesian product of two sets A and B such that $|A| = \mathbf{a}$ and $|B| = \mathbf{b}$.

Exponentiation of cardinal numbers, written $\mathbf{a}^{\mathbf{b}}$, is the cardinality of the set A^B of all functions from B to A, where $|A| = \mathbf{a}$ and $|B| = \mathbf{b}$.

Facts:

1. Axiom 3 in the Peano definition of the natural numbers is the principle of mathematical induction. (See §1.5.4.)

2. The finite cardinal numbers are written $0, 1, 2, 3, \ldots$.

3. The cardinal number of any finite set with n elements is n.

4. The first infinite cardinal numbers are written $\aleph_0, \aleph_1, \aleph_2, \ldots, \aleph_\omega, \ldots$.

5. For each ordinal α, there is a cardinal number $\aleph_\alpha$.

6. The cardinal number of any denumerable set, such as $\mathcal{N}$, $\mathcal{Z}$, and $\mathcal{Q}$, is $\aleph_0$.

7. The cardinal number of $\mathcal{P}(\mathcal{N})$, $\mathcal{R}$, and $\mathcal{C}$ is denoted $\mathbf{c}$ (standing for the *continuum*).

8. The set of algebraic numbers (all solutions of polynomials with integer coefficients) is denumerable.

9. The set $\mathcal{R}$ is uncountable (proved by Georg Cantor in late 19th century, using a diagonal argument). (See §1.5.5.)

10. Every subset of a countable set is countable.

11. The countable union of countable sets is countable.

12. Every set containing an uncountable subset is uncountable.

13. The *continuum problem*, posed by Georg Cantor (1845–1918) and restated by David Hilbert (1862–1943) in 1900, is the problem of determining the cardinality $|\mathcal{R}|$ of the real numbers.

14. The *continuum hypothesis* is the assertion that $|\mathcal{R}| = \aleph_1$, the first cardinal number larger than $\aleph_0$. Equivalently, $2^{\aleph_0} = \aleph_1$. (See Fact 35.) Kurt Gödel (1906–1978) proved in 1938 that the continuum hypothesis is consistent with various other axioms of set theory. Paul Cohen (1934–2007) demonstrated in 1963 that the continuum hypothesis cannot be proved from those other axioms; i.e., it is independent of the other axioms of set theory.

15. The *generalized continuum hypothesis* is the assertion that $2^{\aleph_\alpha} = \aleph_{\alpha+1}$ for all ordinals α. That is, for infinite sets there is no cardinal number strictly between $|S|$ and $|\mathcal{P}(S)|$.

16. The generalized continuum hypothesis is consistent with and independent of the usual axioms of set theory.

17. There is no largest cardinal number.

18. $|A| < |\mathcal{P}(A)|$ for all sets A.

19. *Schröder-Bernstein theorem*: If $|A| \leq |B|$ and $|B| \leq |A|$, then $|A| = |B|$. (This is also called the Cantor-Schröder-Bernstein theorem.)

20. The ordinal number $1 = 0^+ = \{\emptyset\} = \{0\}$, the ordinal number $2 = 1^+ = \{0, 1\}$, etc. In general, for finite ordinals, $n + 1 = n^+ = \{0, 1, 2, \ldots, n\}$.

21. The first limit ordinal is $\omega = \{0, 1, 2, \ldots\}$. Then $\omega + 1 = \omega^+ = \omega \cup \{\omega\} = \{0, 1, 2, \ldots, \omega\}$, and so on. The next limit ordinal is $\omega+\omega = \{0, 1, 2, \ldots, \omega, \omega+1, \omega+2, \ldots\}$, also denoted $\omega \cdot 2$. The process never stops, because the next limit ordinal can always be formed as the union of the infinite process that has gone before.

22. Limit ordinals have no immediate predecessors.

23. The first ordinal that, viewed as a set, is not countable, is denoted ω_1.

24. For ordinals the following are equivalent: $\alpha < \beta$, $\alpha \in \beta$, $\alpha \subset \beta$.

25. Every set of ordinal numbers has a smallest element; i.e., the ordinals are well-ordered. (See §1.4.3.)

26. Ordinal numbers correspond to well-ordered sets (§1.4.3). Two well-ordered sets represent the same ordinal if they can be put into an order-preserving one-to-one correspondence.

27. Addition and multiplication of ordinals are associative operations.

28. Ordinal addition and multiplication for finite ordinals (those less than ω) are the same as ordinary addition and multiplication on the natural numbers.

29. Addition of infinite ordinals is not commutative. (See Example 2.)

30. Multiplication of infinite ordinals is not commutative. (See Example 3.)

31. The ordinals 0 and 1 are identities for addition and multiplication, respectively.

32. Multiplication of ordinals is distributive over addition on the left: $\alpha(\beta + \gamma) = \alpha\beta + \alpha\gamma$. It is not distributive on the right.

33. In the definition of the cardinal number $\mathbf{a}^{\mathbf{b}}$, when $\mathbf{a} = 2$, the set A can be taken to be $A = \{0, 1\}$ and an element of A^B can be identified with a subset of B (namely, those elements of B sent to 1 by the function). Thus $2^{|B|} = |\mathcal{P}(B)|$, the cardinality of the power set of B.

34. If $\mathbf{a}$ and $\mathbf{b}$ are cardinals, at least one of which is infinite, then $\mathbf{a} + \mathbf{b} = \mathbf{a} \cdot \mathbf{b} =$ the larger of $\mathbf{a}$ and $\mathbf{b}$.

35. $\mathbf{c}^{\aleph_0} = \aleph_0^{\aleph_0} = 2^{\aleph_0}$.

36. The usual rules for finite arithmetic continue to hold for infinite cardinal arithmetic (commutativity, associativity, distributivity, and rules for exponents).

Examples:

1. $\omega_1 > \omega \cdot 2$, $\omega_1 > \omega^2$, $\omega_1 > \omega^\omega$.

2. $1 + \omega = \omega$, but $\omega + 1 > \omega$.

3. $2 \cdot \omega = \omega$, but $\omega \cdot 2 > \omega$.

4. $\aleph_0 \cdot \aleph_0 = \aleph_0 + \aleph_0 = \aleph_0$.

1.2.4 AXIOMS FOR SET THEORY

Set theory can be viewed as an axiomatic system, with undefined terms "set" (the universe of discourse) and "is an element of" (a binary relation denoted $\in$).

Definitions:

The ***Axiom of choice*** (***AC***) states: If $\mathcal{A}$ is any set whose elements are pairwise disjoint nonempty sets, then there exists a set X that has as its elements exactly one element from each set in $\mathcal{A}$.

The ***Zermelo-Fraenkel*** (***ZF***) ***axioms*** for set theory: (The axioms are stated informally.)

- *Extensionality* (*equality*): Two sets with the same elements are equal.
- *Pairing*: For every a and b, the set $\{a, b\}$ exists.
- *Specification* (*subset*): If A is a set and $P(x)$ is a predicate with free variable x, then the subset of A exists that consists of those elements $c \in A$ such that $P(c)$ is true. (The specification axiom guarantees that the intersection of two sets exists.)
- *Union*: The union of a set (i.e., the set of all the elements of its elements) exists. (The union axiom together with the pairing axiom implies the existence of the union of two sets.)
- *Power set*: The power set (set of all subsets) of a set exists.
- *Empty set*: The empty set exists.
- *Regularity* (*foundation*): Every nonempty set contains a "foundational" element; that is, every nonempty set contains an element that is not an element of any other element in the set. (The regularity axiom prevents anomalies such as a set being an element of itself.)
- *Replacement*: If f is a function defined on a set A, then the collection of images $\{f(a) \mid a \in A\}$ is a set. The replacement axiom (together with the union axiom) allows the formation of large sets by expanding each element of a set into a set.
- *Infinity*: An infinite set, such as ω (§1.2.3), exists.

Facts:

1. The axiom of choice is consistent with and independent of the other axioms of set theory; it can be neither proved nor disproved from the other axioms of set theory.

2. The axioms of ZF together with the axiom of choice are denoted ZFC.

3. The following propositions are equivalent to the axiom of choice:

- *The well-ordering principle*: Every set can be well-ordered; i.e., for every set A there exists a total ordering on A such that every subset of A contains a smallest element under this ordering.
- *Generalized axiom of choice* (*functional version*): If $\mathcal{A}$ is any collection of nonempty sets, then there is a function f whose domain is $\mathcal{A}$, such that $f(X) \in X$ for all $X \in A$.
- *Zorn's lemma*: Every nonempty partially ordered set in which every chain (totally ordered subset) contains an upper bound (an element greater than all the other elements in the chain) has a maximal element (an element that is less than no other element). (§1.4.3.)

- *The Hausdorff maximal principle*: Every chain in a partially ordered set is contained in a maximal chain (a chain that is not strictly contained in another chain). (§1.4.3.)
- *Trichotomy*: Given any two sets A and B, either there is a one-to-one function from A to B, or there is a one-to-one function from B to A; i.e., either $|A| \leq |B|$ or $|B| \leq |A|$.

1.3 FUNCTIONS

A function is a rule that associates to each object in one set an object in a second set (these sets are often sets of numbers). For instance, the expected population in future years, based on demographic models, is a function from calendar years to numbers. Encryption is a function from confidential information to apparent nonsense messages, and decryption is a function from apparent nonsense back to confidential information. Computer scientists and mathematicians are often concerned with developing methods to calculate particular functions quickly.

1.3.1 BASIC TERMINOLOGY FOR FUNCTIONS

Definitions:

A ***function*** f from a set A to a set B, written $f\colon A \to B$, is a rule that assigns to every object $a \in A$ exactly one element $f(a) \in B$. The set A is the ***domain*** of f; the set B is the ***codomain*** of f; the element $f(a)$ is the ***image*** of a or the ***value*** of f at a. A function f is often identified with its ***graph*** $\{(a,b) \mid a \in A \text{ and } b = f(a)\} \subseteq A \times B$.

Note: The function $f\colon A \to B$ is sometimes represented by the "maps to" notation $x \mapsto f(x)$ or by the variation $x \mapsto \mathit{expr}(x)$, where $\mathit{expr}(x)$ is an expression in x. The notation $f(x) = \mathit{expr}(x)$ is a form of the "maps to" notation without the symbol $\mapsto$.

The rule defining a function $f\colon A \to B$ is called ***well-defined*** since to each $a \in A$ there is associated exactly one element of B.

If $f\colon A \to B$ and $S \subseteq A$, the ***image*** of the subset S under f is the set $f(S) = \{f(x) \mid x \in S\}$.

If $f\colon A \to B$ and $T \subseteq B$, the ***pre-image*** or ***inverse image*** of the subset T under f is the set $f^{-1}(T) = \{x \mid f(x) \in T\}$.

The ***image*** of a function $f\colon A \to B$ is the set $f(A) = \{f(x) \mid x \in A\}$.

The ***range*** of a function $f\colon A \to B$ is the image set $f(A)$. (Some authors use "range" as a synonym for "codomain".)

A function $f\colon A \to B$ is ***one-to-one*** (***1–1***, ***injective***, or a ***monomorphism***) if distinct elements of the domain are mapped to distinct images; i.e., $f(a_1) \neq f(a_2)$ whenever $a_1 \neq a_2$. An ***injection*** is an injective function.

A function $f\colon A \to B$ is ***onto*** (***surjective***, or an ***epimorphism***) if every element of the codomain B is the image of at least one element of A; i.e., if $(\forall b \in B)(\exists a \in A)\ [f(a) = b]$ is true. A ***surjection*** is a surjective function.

A function $f\colon A \to B$ is ***bijective*** (or a ***one-to-one correspondence***) if it is both injective and surjective; i.e., it is 1–1 and onto. A ***bijection*** is a bijective function.

If $f\colon A \to B$ and $S \subseteq A$, the ***restriction*** of f to S is the function $f_S\colon S \to B$ where $f_S(x) = f(x)$ for all $x \in S$. The function f is an ***extension*** of f_S. The restriction of f to S is also written $f|_S$.

A ***partial function*** on a set A is a rule f that assigns to each element in a subset of A exactly one element of B. The subset of A on which f is defined is the ***domain of definition*** of f. In a context that includes partial functions, a rule that applies to all of A is called a ***total function***.

Given a 1–1 onto function $f\colon A \to B$, the ***inverse function*** $f^{-1}\colon B \to A$ has the rule that for each $y \in B$, $f^{-1}(y)$ is the object $x \in A$ such that $f(x) = y$.

If $f\colon A \to B$ and $g\colon B \to C$, then the ***composition*** is the function $g{\circ}f\colon A \to C$ defined by the rule $(g{\circ}f)(x) = g(f(x))$ for all $x \in A$. The function to the right of the raised circle is applied first.

Note: Care must be taken since some sources define the composition $(g{\circ}f)(x) = f(g(x))$ so that the order of application reads left to right.

If $f\colon A \to A$, the ***iterated functions*** $f^n\colon A \to A$ $(n \geq 2)$ are defined recursively by the rule $f^n(x) = f \circ f^{n-1}(x)$.

A function $f\colon A \to A$ is ***idempotent*** if $f \circ f = f$.

A function $f\colon A \to A$ is an ***involution*** if $f \circ f = i_A$. (See Example 1.)

A function whose domain is a Cartesian product $A_1 \times \cdots \times A_n$ is often regarded as a function of n variables (also called a ***multivariate*** function), and the value of f at $(a_1, \ldots, a_n)$ is usually written $f(a_1, \ldots, a_n)$.

An (***n-ary***) ***operation*** on a set A is a function $f\colon A^n \to A$, where $A^n = A \times \cdots \times A$ (with n factors in the product). A 1-ary operation is called ***monadic*** or ***unary***, and a 2-ary operation is called ***binary***.

Facts:

1. The graph of a function $f\colon A \to B$ is a binary relation on $A \times B$. (§1.4.1.)

2. The graph of a function $f\colon A \to B$ is a subset S of $A \times B$ such that for each $a \in A$ there is exactly one $b \in B$ such that $(a, b) \in S$.

3. In general, two or more different objects in the domain of a function might be assigned the same value in the codomain. If this occurs, the function is not 1–1.

4. If $f\colon A \to B$ is bijective, then: $f{\circ}f^{-1} = i_B$ (Example 1), $f^{-1}{\circ}f = i_A$, f^{-1} is bijective, and $(f^{-1})^{-1} = f$.

5. Function composition is associative: $(f{\circ}g){\circ}h = f{\circ}(g{\circ}h)$, whenever $h\colon A \to B$, $g\colon B \to C$, and $f\colon C \to D$.

6. Function composition is not commutative; that is, $f{\circ}g \neq g{\circ}f$ in general. (See Example 12.)

7. *Set operations with functions*: If $f\colon A \to B$ with $S_1, S_2 \subseteq A$ and $T_1, T_2 \subseteq B$, then

- $f(S_1 \cup S_2) = f(S_1) \cup f(S_2)$;
- $f(S_1 \cap S_2) \subseteq f(S_1) \cap f(S_2)$, with equality if f is injective;
- $f(\overline{S_1}) \supseteq \overline{f(S_1)}$ (i.e., $f(A - S_1) \supseteq B - f(S_1)$), with equality if f is injective;

- $f^{-1}(T_1 \cup T_2) = f^{-1}(T_1) \cup f^{-1}(T_2)$;
- $f^{-1}(T_1 \cap T_2) = f^{-1}(T_1) \cap f^{-1}(T_2)$;
- $f^{-1}(\,\overline{T_1}\,) = \overline{f^{-1}(T_1)}$ (i.e., $f^{-1}(B - T_1) = A - f^{-1}(T_1)$);
- $f^{-1}(f(S_1)) \supseteq S_1$, with equality if f is injective;
- $f(f^{-1}(T_1)) \subseteq T_1$, with equality if f is surjective.

8. If $f\colon A \to B$ and $g\colon B \to C$ are both bijective, then $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$.

9. If an operation $*$ (such as addition) is defined on a set B, then that operation can be extended to the set of all functions from a set A to B, by setting $(f * g)(x) = f(x) * g(x)$.

10. *Numbers of functions*: If $|A| = m$ and $|B| = n$, the numbers of different types of functions $f\colon A \to B$ are given in the following list:

- all: n^m (§2.2.1)
- one-to-one: $P(n,m) = n(n-1)(n-2)\dots(n-m+1)$ if $n \geq m$ (§2.2.1)
- onto: $\sum_{j=0}^{n}(-1)^j\binom{n}{j}(n-j)^m$ if $m \geq n$ (§2.4.2)
- partial: $(n+1)^m$ (§2.3.2)

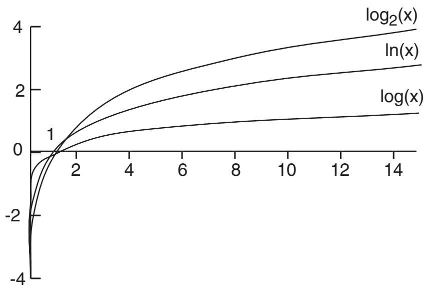
Examples:

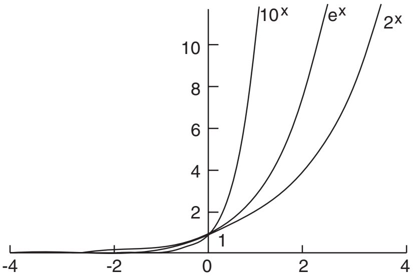
1. The following are some common functions:

- ***exponential function to base*** b (for $b > 0$, $b \neq 1$): the function $f\colon \mathcal{R} \to \mathcal{R}^+$ where $f(x) = b^x$. (See the following figure.) ($\mathcal{R}^+$ is the set of positive real numbers.)
- ***logarithm function with base*** b (for $b > 0$, $b \neq 1$): the function $\log_b\colon \mathcal{R}^+ \to \mathcal{R}$ that is the inverse of the exponential function to base b; that is,

$$\log_b x = y \text{ if and only if } b^y = x.$$

- ***common logarithm function***: the function $\log_{10}\colon \mathcal{R}^+ \to \mathcal{R}$ (also written log) that is the inverse of the exponential function to base 10; i.e., $\log_{10} x = y$ when $10^y = x$. (See the following figure.)
- ***binary logarithm function***: the function $\log_2\colon \mathcal{R}^+ \to \mathcal{R}$ (also denoted log or lg) that is the inverse of the exponential function to base 2; i.e., $\log_2 x = y$ when $2^y = x$. (See the following figure.)
- ***natural logarithm function***: the function $\ln\colon \mathcal{R}^+ \to \mathcal{R}$ is the inverse of the exponential function to base e; i.e., $\ln(x) = y$ when $e^y = x$, where $e = \lim_{n\to\infty}(1+\frac{1}{n})^n \approx 2.718281828459$. (See the following figure.)

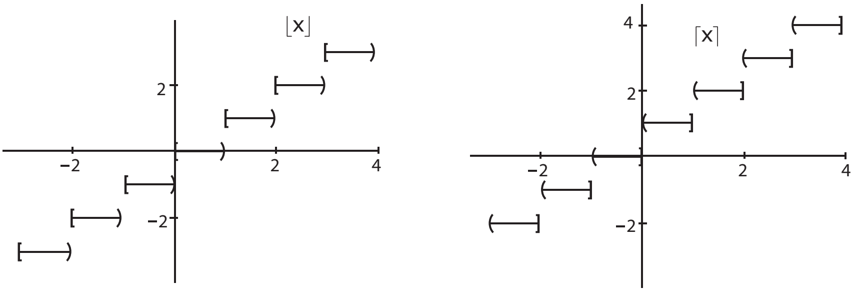




- ***iterated logarithm***: the function $\log^* \colon \mathcal{R}^+ \to \{0, 1, 2, \ldots\}$, where $\log^* x$ is the smallest nonnegative integer k such that $\log^{(k)} x \leq 1$; the function $\log^{(k)}$ is defined recursively by

$$\log^{(k)} x = \begin{cases} x & \text{if } k = 0 \\ \log(\log^{(k-1)} x) & \text{if } \log^{(k-1)} x \text{ is defined and positive} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

- ***mod function***: for a given positive integer n, the function $f \colon \mathcal{Z} \to \mathcal{N}$ defined by the rule $f(k) = k \textbf{ mod } n$, where $k \textbf{ mod } n$ is the remainder when the division algorithm is used to divide k by n. (See §4.1.2.)
- ***identity function*** on a set A: the function $i_A \colon A \to A$ such that $i_A(x) = x$ for all $x \in A$.
- ***characteristic function*** of S: for $S \subseteq A$, the function $\chi_S \colon A \to \{0, 1\}$ given by $\chi_S(x) = 1$ if $x \in S$ and $\chi_S(x) = 0$ if $x \notin S$.
- ***projection function***: the function $\pi_j \colon A_1 \times \cdots \times A_n \to A_j$ $(j = 1, 2, \ldots, n)$ such that $\pi_j(a_1, \ldots, a_n) = a_j$.
- ***permutation***: a function $f \colon A \to A$ that is 1–1 and onto.
- ***floor function*** (sometimes referred to, especially in number theory, as the ***greatest integer function***): the function $\lfloor\ \rfloor \colon \mathcal{R} \to \mathcal{Z}$ where $\lfloor x \rfloor =$ the greatest integer less than or equal to x. The floor of x is also written $[x]$. (See the following figure.) Thus $\lfloor \pi \rfloor = 3$, $\lfloor 6 \rfloor = 6$, and $\lfloor -0.2 \rfloor = -1$.
- ***ceiling function***: the function $\lceil\ \rceil \colon \mathcal{R} \to \mathcal{Z}$ where $\lceil x \rceil =$ the smallest integer greater than or equal to x. (See the following figure.) Thus $\lceil \pi \rceil = 4$, $\lceil 6 \rceil = 6$, and $\lceil -0.2 \rceil = 0$.



2. The floor and ceiling functions are total functions from the reals $\mathcal{R}$ to the integers $\mathcal{Z}$. They are onto, but not one-to-one.

3. *Properties of the floor and ceiling functions* (m and n represent arbitrary integers):

- $\lfloor x \rfloor = n$ if and only if $n \leq x < n + 1$ if and only if $x - 1 < n \leq x$;
- $\lceil x \rceil = n$ if and only if $n - 1 < x \leq n$ if and only if $x \leq n < x + 1$;
- $\lfloor x \rfloor < n$ if and only if $x < n$; $\lceil x \rceil \leq n$ if and only if $x \leq n$;
- $n \leq \lfloor x \rfloor$ if and only if $n \leq x$; $n < \lceil x \rceil$ if and only if $n < x$;
- $x - 1 < \lfloor x \rfloor \leq x \leq \lceil x \rceil < x + 1$;
- $\lfloor x \rfloor = x$ if and only if x is an integer;
- $\lceil x \rceil = x$ if and only if x is an integer;

- $\lfloor -x \rfloor = -\lceil x \rceil$; $\lceil -x \rceil = -\lfloor x \rfloor$;
- $\lfloor x+n \rfloor = \lfloor x \rfloor + n$; $\lceil x+n \rceil = \lceil x \rceil + n$;
- the interval $[x_1, x_2]$ contains $\lfloor x_2 \rfloor - \lceil x_1 \rceil + 1$ integers;
- the interval $[x_1, x_2)$ contains $\lceil x_2 \rceil - \lceil x_1 \rceil$ integers;
- the interval $(x_1, x_2]$ contains $\lfloor x_2 \rfloor - \lfloor x_1 \rfloor$ integers;
- the interval (x_1, x_2) contains $\lceil x_2 \rceil - \lfloor x_1 \rfloor - 1$ integers;
- if $f(x)$ is a continuous, monotonically increasing function, and whenever $f(x)$ is an integer, x is also an integer, then $\lfloor f(x) \rfloor = \lfloor f(\lfloor x \rfloor) \rfloor$ and $\lceil f(x) \rceil = \lceil f(\lceil x \rceil) \rceil$;
- if $n > 0$, then $\lfloor \frac{x+m}{n} \rfloor = \lfloor \frac{\lfloor x \rfloor + m}{n} \rfloor$ and $\lceil \frac{x+m}{n} \rceil = \lceil \frac{\lceil x \rceil + m}{n} \rceil$ (a special case of the preceding fact);
- if $m > 0$, then $\lfloor mx \rfloor = \lfloor x \rfloor + \lfloor x + \frac{1}{m} \rfloor + \cdots + \lfloor x + \frac{m-1}{m} \rfloor$.

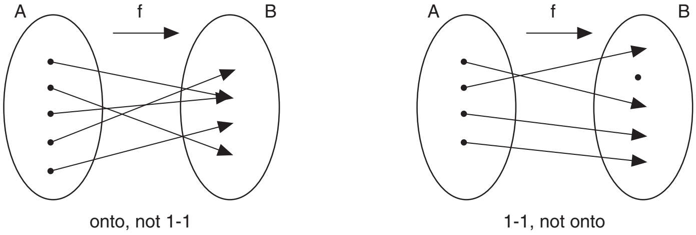
4. The logarithm function $\log_b x$ is bijective from the positive reals $\mathcal{R}^+$ to the reals $\mathcal{R}$.

5. The logarithm function $x \mapsto \log_b x$ is the inverse of the function $x \mapsto b^x$, if the codomain of $x \mapsto b^x$ is the set of positive real numbers. If the domain and codomain are considered to be $\mathcal{R}$, then $x \mapsto \log_b x$ is only a partial function, because the logarithm of a nonpositive number is not defined.

6. All logarithm functions are related according to the following change of base formula: $\log_b x = \frac{\log_a x}{\log_a b}$.

7. $\log^* 2 = 1$, $\log^* 4 = 2$, $\log^* 16 = 3$, $\log^* 65536 = 4$, $\log^* 2^{65536} = 5$.

8. The diagrams in the following figure illustrate a function that is onto but not 1–1 and a function that is 1–1 but not onto.



9. If the domain and codomain are considered to be the nonnegative reals, then the function $x \mapsto x^2$ is a bijection, and $x \mapsto \sqrt{x}$ is its inverse.

10. If the codomain is considered to be the subset of complex numbers with polar coordinate $0 \le \theta < \pi$, then $x \mapsto \sqrt{x}$ can be regarded as a total function.

11. Division of real numbers is a multivariate function from $\mathcal{R} \times (\mathcal{R} - \{0\})$ to $\mathcal{R}$, given by the rule $f(x, y) = \frac{x}{y}$. Similarly, addition, subtraction, and multiplication are functions from $\mathcal{R} \times \mathcal{R}$ to $\mathcal{R}$.

12. If $f(x) = x^2$ and $g(x) = x + 1$, then $(f \circ g)(x) = (x+1)^2$ and $(g \circ f)(x) = x^2 + 1$. (Therefore, composition of functions is not commutative.)

13. *Collatz conjecture*: If $f\colon \{1, 2, 3, \ldots\} \to \{1, 2, 3, \ldots\}$ is defined by the rule $f(n) = \frac{n}{2}$ if n is even and $f(n) = 3n + 1$ if n is odd, then for each positive integer m there is a positive integer k such that the iterated function $f^k(m) = 1$. It is not known whether this conjecture is true.

1.3.2 COMPUTATIONAL REPRESENTATION

A given function may be described by several different rules. These rules can then be used to evaluate specific values of the function. There is often a large difference in the time required to compute the value of a function using different computational rules. The speed usually depends on the representation of the data as well as on the computational process.

Definitions:

A (***computational***) ***representation*** of a function is a way to calculate its values.

A ***closed formula*** for a function value $f(x)$ is an algebraic expression in the argument x.

A ***table of values*** for a function $f\colon A \to B$ with finite domain A is any explicit representation of the set $\{(a, f(a)) \in A \times B \mid a \in A\}$.

An ***infinite sequence*** in a set S is a function from the natural numbers $\{0, 1, 2, \ldots\}$ to the set S. It is commonly represented as a list $x_0, x_1, x_2, \ldots$ such that each $x_j \in S$. Sequences are often permitted to start at the index 1 or elsewhere, rather than 0.

A ***finite sequence*** in a set S is a function from $\{1, 2, \ldots, n\}$ to the set S. It is commonly represented as a list $x_1, x_2, \ldots, x_n$ such that each $x_j \in S$. Finite sequences are often permitted to start at the index 0 (or at some other value of the index), rather than at the index 1.

A value of a sequence is also called an ***entry***, an ***item***, or a ***term***.

A ***string*** is a representation of a sequence as a list in which the successive entries are juxtaposed without intervening punctuation or extra spacing.

A ***recursive definition*** of a function f with domain S has two parts: there is a set of ***base values*** (or ***initial values***) B on which the value of f is specified, and there is a rule for calculating $f(x)$ for every $x \in S - B$ in terms of previously defined values of f.

Ackermann's function (Wilhelm Ackermann, 1896–1962) is defined recursively by

$$A(x,y,z) = \begin{cases} x + y & \text{if } z = 0 \\ 0 & \text{if } y = 0,\ z = 1 \\ 1 & \text{if } y = 0,\ z = 2 \\ x & \text{if } y = 0,\ z > 2 \\ A(x, A(x, y-1, z), z-1) & \text{if } y,\ z > 0. \end{cases}$$

An alternative version of Ackermann's function, with two variables, is defined recursively by

$$A(m,n) = \begin{cases} n + 1 & \text{if } m = 0 \\ A(m-1, 1) & \text{if } m > 0,\ n = 0 \\ A(m-1, A(m, n-1)) & \text{if } m,\ n > 0. \end{cases}$$

Another alternative version of Ackermann's function is defined recursively by the rule $A(n) = A_n(n)$, where $A_1(n) = 2n$ and $A_m(n) = A_{m-1}^{(n)}(1)$ if $m \geq 2$.

The (input-independent) ***halting function*** maps computer programs to the set $\{0, 1\}$, with value 1 if the program always halts, regardless of input, and 0 otherwise.

Facts:

1. If $f\colon \mathcal{N} \to \mathcal{R}$ is recursively defined, the set of base values is frequently the set $\{f(0), f(1), \ldots, f(j)\}$ and there is a rule for calculating $f(n)$ for every $n > j$ in terms of $f(i)$ for one or more $i < n$.

2. There are functions whose values cannot be computed. (See Example 5.)

3. There are recursively-defined functions that cannot be represented by a closed formula.

4. It is possible to find closed formulas for the values of some functions defined recursively. See Chapter 3 for more information.

5. Computer software developers often represent a table as a *binary search tree* (§18.2.3).

6. In Ackermann's function of three variables $A(x, y, z)$, as the variable z ranges from 0 to 3, $A(x, y, z)$ is the sum of x and y, the product of x and y, x raised to the exponent y, and the iterated exponentiation of x y times. That is, $A(x, y, 0) = x + y$, $A(x, y, 1) = xy$, $A(x, y, 2) = x^y$, $A(x, y, 3) = x^{x^{\cdot^{\cdot^{\cdot^{x}}}}}$ (y xs in the exponent).

7. The version of Ackermann's function with two variables, $A(x, y)$, has the following properties: $A(1, n) = n + 2$, $A(2, n) = 2n + 3$, $A(3, n) = 2^{n+3} - 3$.

8. $A(m, n)$ is an example of a well-defined total function that is computable, but not primitive recursive. (See §17.2.1.)

Examples:

1. The function that maps each month to its ordinal position is represented by the table

$$\{(\text{Jan}, 1), (\text{Feb}, 2), \ldots, (\text{Dec}, 12)\}.$$

2. The function defined by the recurrence relation

$$f(0) = 0; \quad f(n) = f(n-1) + 2n - 1 \text{ for } n \geq 1$$

has the closed form $f(x) = x^2$.

3. The function defined by the recurrence relation

$$f(0) = 0,\ f(1) = 1; \quad f(n) = f(n-1) + f(n-2) \text{ for } n \geq 2$$

generates the Fibonacci sequence $0, 1, 1, 2, 3, 5, 8, \ldots$ (see §3.1.2) and has the closed form

$$f(n) = \frac{(1+\sqrt{5})^n - (1-\sqrt{5})^n}{2^n\sqrt{5}}.$$

4. The factorial function $n!$ is recursively defined by the rules

$$0! = 1; \quad n! = n \cdot (n-1)! \ \text{ for } n \geq 1.$$

It has no known closed formula in terms of elementary functions.

5. It is impossible to construct an algorithm to compute the halting function.

6. The halting function from the Cartesian product of the set of computer programs and the set of strings to $\{0, 1\}$ whose value is 1 if the program halts when given that string as input and 0 if the program does not halt when given that string as input is noncomputable.

7. The following is not a well-defined function $f\colon \{1,2,3,\ldots\} \to \{1,2,3,\ldots\}$

$$f(n) = \begin{cases} 1 & \text{if } n = 1 \\ 1 + f(\frac{n}{2}) & \text{if } n \text{ is even} \\ f(3n-1) & \text{if } n \text{ is odd, } n > 1 \end{cases}$$

since evaluating $f(5)$ leads to the contradiction $f(5) = f(5) + 3$.

8. It is not known whether the following is a well-defined function $f\colon \{1,2,3,\ldots\} \to \{1,2,3,\ldots\}$

$$f(n) = \begin{cases} 1 & n = 1 \\ 1 + f(\frac{n}{2}) & n \text{ even} \\ f(3n+1) & n \text{ odd, } n > 1. \end{cases}$$

(See §1.3.1, Example 13.)

1.3.3 ASYMPTOTIC BEHAVIOR

The asymptotic growth of functions is commonly described with various special pieces of notation and is regularly used in the analysis of computer algorithms to estimate the length of time the algorithms take to run and the amount of computer memory they require.

Definitions:

A function $f\colon \mathcal{R} \to \mathcal{R}$ or $f\colon \mathcal{N} \to \mathcal{R}$ is ***bounded*** if there is a constant k such that $|f(x)| \le k$ for all x in the domain of f.

For functions $f, g\colon \mathcal{R} \to \mathcal{R}$ or $f, g\colon \mathcal{N} \to \mathcal{R}$ (sequences of real numbers) the following are used to compare their growth rates:

- f is ***big-oh*** of g (g ***dominates*** f) if there exist constants C and k such that $|f(x)| \le C|g(x)|$ for all $x > k$.

  Notation: f is $O(g)$, $f(x) \in O(g(x))$, $f \in O(g)$, $f = O(g)$.

- f is ***little-oh*** of g if $\lim_{x\to\infty} |\frac{f(x)}{g(x)}| = 0$; i.e., for every $C > 0$ there is a constant k such that $|f(x)| \le C|g(x)|$ for all $x > k$.

  Notation: f is $o(g)$, $f(x) \in o(g(x))$, $f \in o(g)$, $f = o(g)$.

- f is ***big omega of*** g if there are constants C and k such that $|g(x)| \le C|f(x)|$ for all $x > k$.

  Notation: f is $\Omega(g)$, $f(x) \in \Omega(g(x))$, $f \in \Omega(g)$, $f = \Omega(g)$.

- f is ***little omega of*** g if $\lim_{x\to\infty} |\frac{g(x)}{f(x)}| = 0$.

  Notation: f is $\omega(g)$, $f(x) \in \omega(g(x))$, $f \in \omega(g)$, $f = \omega(g)$.

- f is ***theta of*** g if there are positive constants C_1, C_2, and k such that $C_1|g(x)| \le |f(x)| \le C_2|g(x)|$ for all $x > k$.

  Notation: f is $\Theta(g)$, $f(x) \in \Theta(g(x))$, $f \in \Theta(g)$, $f = \Theta(g)$, $f \approx g$.

- f is ***asymptotic*** to g if $\lim_{x\to\infty} \frac{g(x)}{f(x)} = 1$. This relation is sometimes called ***asymptotic equality*** and is denoted $f \sim g$ or $f(x) \sim g(x)$.

Facts:

1. The notations $O(\ )$, $o(\ )$, $\Omega(\ )$, $\omega(\ )$, and $\Theta(\ )$ all stand for *collections* of functions. Hence the equality sign, as in $f = O(g)$, does not mean equality of functions.

2. The symbols $O(g)$, $o(g)$, $\Omega(g)$, $\omega(g)$, and $\Theta(g)$ are frequently used to represent a typical element of the class of functions it represents, as in an expression such as $f(n) = n \log n + o(n)$.

3. *Growth rates*:

- $O(g)$: the set of functions that grow no more rapidly than a positive multiple of g;
- $o(g)$: the set of functions that grow less rapidly than a positive multiple of g;
- $\Omega(g)$: the set of functions that grow at least as rapidly as a positive multiple of g;
- $\omega(g)$: the set of functions that grow more rapidly than a positive multiple of g;
- $\Theta(g)$: the set of functions that grow at the same rate as a positive multiple of g.

4. Asymptotic notation can be used to describe the growth of infinite sequences, since infinite sequences are functions from $\{0, 1, 2, \ldots\}$ or $\{1, 2, 3, \ldots\}$ to $\mathcal{R}$ (by considering the term a_n as $a(n)$, the value of the function $a(n)$ at the integer n).

5. The big-oh notation was introduced in 1892 by Paul Bachmann (1837–1920) in the study of the rates of growth of various functions in number theory.

6. The big-oh symbol is often called a *Landau symbol*, after Edmund Landau (1877–1938), who popularized this notation.

7. *Properties of big-oh*:

- if $f \in O(g)$ and c is a constant, then $cf \in O(g)$;
- if $f_1, f_2 \in O(g)$, then $f_1 + f_2 \in O(g)$;
- if $f_1 \in O(g_1)$ and $f_2 \in O(g_2)$, then
  - ◇ $(f_1 + f_2) \in O(g_1 + g_2)$
  - ◇ $(f_1 + f_2) \in O(\max(|g_1|, |g_2|))$
  - ◇ $(f_1 f_2) \in O(g_1 g_2)$;
- if f is a polynomial of degree n, then $f \in O(x^n)$;
- if f is a polynomial of degree m and g a polynomial of degree n, with $m \geq n$, then $\frac{f}{g} \in O(x^{m-n})$;
- if f is a bounded function, then $f \in O(1)$;
- for all $a, b > 1$, $O(\log_a x) = O(\log_b x)$;
- if $f \in O(g)$ and $|h(x)| \geq |g(x)|$ for all $x > k$, then $f \in O(h)$;
- if $f \in O(x^m)$, then $f \in O(x^n)$ for all $n > m$.

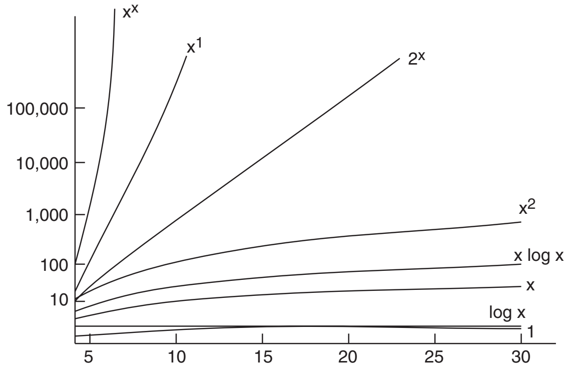
8. Some of the most commonly used benchmark big-oh classes are: $O(1)$, $O(\log x)$, $O(x)$, $O(x \log x)$, $O(x^2)$, $O(2^x)$, $O(x!)$, and $O(x^x)$. If f is big-oh of any function in this list, then f is also big-oh of each of the following functions in the list:

$$O(1) \subset O(\log x) \subset O(x) \subset O(x \log x) \subset O(x^2) \subset O(2^x) \subset O(x!) \subset O(x^x).$$

The benchmark functions are drawn in the following figure.

9. *Properties of little-oh*:

- if $f \in o(g)$, then $cf \in o(g)$ for all nonzero constants c;
- if $f_1 \in o(g)$ and $f_2 \in o(g)$, then $f_1 + f_2 \in o(g)$;



- if $f_1 \in o(g_1)$ and $f_2 \in o(g_2)$, then
  $\diamond$ $(f_1 + f_2) \in o(g_1 + g_2)$
  $\diamond$ $(f_1 + f_2) \in o(\max(|g_1|, |g_2|))$
  $\diamond$ $(f_1 f_2) \in o(g_1 g_2)$;
- if f is a polynomial of degree m and g a polynomial of degree n with $m < n$, then $\frac{f}{g} \in o(1)$;
- the set membership $f(x) \in L + o(1)$ is equivalent to $f(x) \to L$ as $x \to \infty$, where L is a constant.

10. If $f \in o(g)$, then $f \in O(g)$; the converse is not true.

11. If $f \in O(g)$ and $h \in o(f)$, then $h \in o(g)$.

12. If $f \in o(g)$ and $h \in O(f)$, then $h \in O(g)$.

13. If $f \in O(g)$ and $h \in O(f)$, then $h \in O(g)$.

14. If $f_1 \in o(g_1)$ and $f_2 \in O(g_2)$, then $f_1 f_2 \in o(g_1 g_2)$.

15. $f \in O(g)$ if and only if $g \in \Omega(f)$.

16. $f \in \Theta(g)$ if and only if $f \in O(g)$ and $g \in O(f)$.

17. $f \in \Theta(g)$ if and only if $f \in O(g)$ and $f \in \Omega(g)$.

18. If $f(x) = a_n x^n + \cdots + a_1 x + a_0$ ($a_n \neq 0$), then $f \sim a_n x^n$.

19. $f \sim g$ if and only if $\left(\frac{f}{g} - 1\right) \in o(1)$ (provided $g(x) = 0$ only finitely often).

Examples:

1. $5x^8 + 10^{200}x^5 + 3x + 1 \in O(x^8)$.

2. $x^3 \in O(x^4)$, $x^4 \notin O(x^3)$.

3. $x^3 \in o(x^4)$, $x^4 \notin o(x^3)$.

4. $x^3 \notin o(x^3)$.

5. $x^2 \in O(5x^2)$, $x^2 \notin o(5x^2)$.

6. $\sin(x) \in O(1)$.

7. $\frac{x^7 - 3x}{8x^3 + 5} \in O(x^4)$, $\frac{x^7 - 3x}{8x^3 + 5} \in \Theta(x^4)$.

8. $1 + 2 + 3 + \cdots + n \in O(n^2)$.

9. $1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n} \in O(\log n)$.

10. $\log(n!) \in O(n \log n)$.

11. $8x^5 \in \Theta(3x^5)$.

12. $x^3 \in \Omega(x^2)$.

13. $2^n + o(n^2) \sim 2^n$.

14. Sometimes asymptotic equality does not behave like equality: $\ln n \sim \ln(2n)$, but $n \not\sim 2n$ and $\ln n - \ln n \not\sim \ln(2n) - \ln n$.

15. $\pi(n) \sim \frac{n}{\ln n}$ where $\pi(n)$ is the number of primes less than or equal to n.

16. If p_n is the nth prime, then $p_n \sim n \ln n$.

17. *Stirling's formula*: $n! \sim \sqrt{2\pi n}(\frac{n}{e})^n$.

1.4 RELATIONS

Relationships between two sets (or among more than two sets) occur frequently throughout mathematics and its applications. Examples of such relationships include integers and their divisors, real numbers and their logarithms, corporations and their customers, cities and airlines that serve them, people and their relatives. These relationships can be described as subsets of product sets.

Functions are a special type of relation. Equivalence relations can be used to describe similarity among elements of sets and partial order relations describe the relative size of elements of sets.

1.4.1 BINARY RELATIONS AND THEIR PROPERTIES

Definitions:

A ***binary relation*** from set A to set B is any subset R of $A \times B$.

An element $a \in A$ ***is related to*** $b \in B$ in the relation R if $(a, b) \in R$, often written aRb. If $(a, b) \notin R$, write $a \not R b$.

A ***binary relation*** (***relation***) on a set A is a binary relation from A to A; i.e., a subset of $A \times A$.

A binary relation R on A can have the following properties (to have the property, the relation must satisfy the property for all $a, b, c \in A$):

- ***reflexivity***: aRa
- ***irreflexivity***: $a \not R a$
- ***symmetry***: if aRb, then bRa
- ***asymmetry***: if aRb, then $b \not R a$
- ***antisymmetry***: if aRb and bRa, then $a = b$
- ***transitivity***: if aRb and bRc, then aRc
- ***intransitivity***: if aRb and bRc, then $a \not R c$

Binary relations R and S from A to B can be combined in the following ways to yield other relations:

- ***complement*** of R: the relation $\overline{R}$ from A to B where $a\overline{R}b$ if and only if $a \not R b$ (i.e., $\neg(aRb)$)

- ***difference***: the binary relation $R - S$ from A to B such that $a(R-S)b$ if and only if aRb and $\neg(aSb)$
- ***intersection***: the relation $R \cap S$ from A to B where $a(R \cap S)b$ if and only if aRb and aSb
- ***inverse*** (***converse***): the relation R^{-1} from B to A where $bR^{-1}a$ if and only if aRb
- ***symmetric difference***: the relation $R \oplus S$ from A to B where $a(R \oplus S)b$ if and only if exactly one of the following is true: aRb, aSb
- ***union***: the relation $R \cup S$ from A to B where $a(R \cup S)b$ if and only if aRb or aSb.

The ***closure*** of a relation R with respect to a property $\mathcal{P}$ is the relation S, if it exists, that has property $\mathcal{P}$ and contains R, such that S is a subset of every relation that has property $\mathcal{P}$ and contains R.

A relation R on A is ***connected*** if for all $a, b \in A$ with $a \neq b$, either aRb or there are $c_1, c_2, \ldots, c_k \in A$ such that aRc_1, $c_1Rc_2, \ldots,$ $c_{k-1}Rc_k$, c_kRb.

If R is a relation on A, the ***connectivity relation associated with*** R is the relation R' where $aR'b$ if and only if aRb or there are $c_1, c_2, \ldots, c_k \in A$ such that aRc_1, $c_1Rc_2, \ldots,$ $c_{k-1}Rc_k$, c_kRb.

If R is a binary relation from A to B and if S is a binary relation from B to C, then the ***composition*** of R and S is the binary relation $S \circ R$ from A to C where $a(S \circ R)c$ if and only if there is an element $b \in B$ such that aRb and bSc.

The ***nth power*** (n a nonnegative integer) of a relation R on a set A, is the relation R^n, where $R^0 = \{(a,a) \mid a \in A\} = I_A$ (see Example 4), $R^1 = R$ and $R^n = R^{n-1} \circ R$ for all integers $n > 1$.

A ***transitive reduction*** of a relation, if it exists, is a relation with the same transitive closure as the original relation and with a minimal superset of ordered pairs.

Notation:

1. If a relation R is symmetric, aRb is often written $a \sim b$, $a \approx b$, or $a \equiv b$.

2. If a relation R is antisymmetric, aRb is often written $a \leq b$, $a < b$, $a \subset b$, $a \subseteq b$, $a \preceq b$, $a \prec b$, or $a \sqsubseteq b$.

Facts:

1. A binary relation R from A to B can be viewed as a function from the Cartesian product $A \times B$ to the boolean domain $\{\text{TRUE}, \text{FALSE}\}$ (often written $\{T, F\}$). The truth value of the pair (a,b) determines whether a is related to b.

2. Under the *infix convention* for a binary relation, aRb (*a is related to b*) means $R(a,b) = \text{TRUE}$; $a\not{R}b$ (*a is not related to b*) means $R(a,b) = \text{FALSE}$.

3. A binary relation R from A to B can be represented in any of the following ways:

- a set $R \subseteq A \times B$, where $(a,b) \in R$ if and only if aRb (this is the definition of R);
- a directed graph D_R whose vertices are the elements of $A \cup B$, with an edge from vertex a to vertex b if aRb (§8.3.1);
- a matrix (the adjacency matrix for the directed graph D_R): if $A = \{a_1, \ldots, a_m\}$ and $B = \{b_1, \ldots, b_n\}$, the matrix for the relation R is the $m \times n$ matrix M_R with entries m_{ij} where $m_{ij} = 1$ if a_iRb_j and $m_{ij} = 0$ otherwise.

4. R is a reflexive relation on A if and only if $\{(a,a) \mid a \in A\} \subseteq R$; i.e., R is a reflexive relation on A if and only if $I_A \subseteq R$.

5. R is symmetric if and only if $R = R^{-1}$.

6. R is an antisymmetric relation on A if and only if $R \cap R^{-1} \subseteq \{(a,a) \mid a \in A\}$.

7. R is transitive if and only if $R \circ R \subseteq R$.

8. A relation R can be both symmetric and antisymmetric: for example, the equality relation on a set A.

9. For a relation R that is both symmetric and antisymmetric: R is reflexive if and only if R is the equality relation on some set; R is irreflexive if and only if $R = \emptyset$.

10. The closure of a relation R with respect to a property $\mathcal{P}$ is the intersection of all relations Q with property $\mathcal{P}$ such that $R \subseteq Q$, if there is at least one such relation Q.

11. The transitive closure of a relation R is the connectivity relation R' associated with R, which is equal to the union $\bigcup_{i=1}^{\infty} R^i$ of all the positive powers of the relation.

12. A transitive reduction of a relation may contain pairs not in the original relation (Example 8).

13. Transitive reductions are not necessarily unique (Example 9).

14. If R is a relation on A and $x, y \in A$ with $x \neq y$, then x is related to y in the transitive closure of R if and only if there is a nontrivial directed path from x to y in the directed graph D_R of the relation.

15. The following table shows how to obtain various closures of a relation and gives the matrices for the various closures of a relation R with matrix M_R on a set A where $|A| = n$.

relation	*set*	*matrix*
reflexive closure	$R \cup \{(a,a) \mid a \in A\}$	$M_R \vee I_n$
symmetric closure	$R \cup R^{-1}$	$M_R \vee M_{R^{-1}}$
transitive closure	$\bigcup_{i=1}^{n} R^i$	$M_R \vee M_R^{[2]} \vee \cdots \vee M_R^{[n]}$

Here the matrix I_n is the $n \times n$ identity matrix, $M_R^{[i]}$ is the ith boolean power of the matrix M_R for the relation R, and $\vee$ is the join operator (defined by $0 \vee 0 = 0$ and $0 \vee 1 = 1 \vee 0 = 1 \vee 1 = 1$).

16. The following table provides formulas for the number of binary relations with various properties on a set with n elements.

type of relation	*number of relations*
all relations	2^{n^2}
reflexive	$2^{n(n-1)}$
symmetric	$2^{n(n+1)/2}$
transitive	*no known simple closed formula (§3.1.8)*
antisymmetric	$2^n \cdot 3^{n(n-1)/2}$
asymmetric	$3^{n(n-1)/2}$
irreflexive	$2^{n(n-1)}$
equivalence (§1.4.2)	B_n = *Bell number* = $\sum_{k=1}^{n} \left\{ {n \atop k} \right\}$ *where* $\left\{ {n \atop k} \right\}$ *is a Stirling subset number (§2.5.2)*
partial order (§1.4.3)	*no known simple closed formula (§3.1.8)*

Algorithm:

1. Warshall's algorithm, also called the Roy-Warshall algorithm (B. Roy and S. Warshall described the algorithm in 1959 and 1960, respectively), Algorithm 1, is an algorithm of order n^3 for finding the transitive closure of a relation on a set with n elements. (Stephen Warshall, 1935–2006.)

Algorithm 1: **Warshall's algorithm.**

```
input: $M = [m_{ij}]_{n\times n}$ = the matrix representing the binary relation $R$
output: $M$ = the transitive closure of relation $R$
for $k := 1$ to $n$
  for $i := 1$ to $n$
    for $j := 1$ to $n$
      $m_{ij} := m_{ij} \vee (m_{ik} \wedge m_{kj})$
```

Examples:

1. Some common relations and whether they have certain properties are given in the following table:

set	relation	reflexive	symmetric	antisymmetric	transitive
any nonempty set	$=$	yes	yes	yes	yes
any nonempty set	$\neq$	no	yes	no	no
$\mathcal{R}$	$\leq$ (or $\geq$)	yes	no	yes	yes
$\mathcal{R}$	$<$ (or $>$)	no	no	yes	yes
positive integers	is a divisor of	yes	no	yes	yes
nonzero integers	is a divisor of	yes	no	no	yes
integers	congruence mod n	yes	yes	no	yes
any set of sets	$\subseteq$ (or $\supseteq$)	yes	no	yes	yes
any set of sets	$\subset$ (or $\supset$)	no	no	yes	yes

2. If A is any set, the *universal relation* is the relation R on $A \times A$ such that aRb for all $a, b \in A$; i.e., $R = A \times A$.

3. If A is any set, the *empty relation* is the relation R on $A \times A$ where aRb is never true; i.e., $R = \emptyset$.

4. If A is any set, the relation R on A where aRb if and only if $a = b$ is the *identity* (or *diagonal*) *relation* $I = I_A = \{(a, a) \mid a \in A\}$, which is also written Δ or Δ_A.

5. Every function $f\colon A \to B$ induces a binary relation R_f from A to B under the rule aR_fb if and only if $f(a) = b$.

6. For $A = \{2, 3, 4, 6, 12\}$, suppose that aRb means that a is a divisor of b. Then R can be represented by the set

$$\{(2,2), (2,4), (2,6), (2,12), (3,3), (3,6), (3,12), (4,4), (4,12), (6,6), (6,12), (12,12)\}.$$

The relation R can also be represented by the digraph with the adjacency matrix

$$\begin{pmatrix} 1 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

7. The transitive closure of the relation $\{(1,3),(2,3),(3,2)\}$ on $\{1,2,3\}$ is the relation $\{(1,2),(1,3),(2,2),(2,3),(3,2),(3,3)\}$.

8. The transitive closure of the relation $R = \{(1,2),(2,3),(3,1)\}$ on $\{1,2,3\}$ is the universal relation $\{1,2,3\} \times \{1,2,3\}$. A transitive reduction of R is the relation given by $\{(1,3),(3,2),(2,1)\}$. This shows that a transitive reduction may contain pairs that are not in the original relation.

9. If $R = \{(a,b) \mid aRb \text{ for all } a,b \in \{1,2,3\}\}$, then the relations $\{(1,2),(2,3),(3,1)\}$ and $\{(1,3),(3,2),(2,1)\}$ are both transitive reductions for R. Thus, transitive reductions are not unique.

1.4.2 EQUIVALENCE RELATIONS

Equivalence relations are binary relations that describe various types of similarity or "equality" among elements in a set. The elements that look alike or behave in a similar way are grouped together in equivalence classes, resulting in a partition of the set. Any element chosen from an equivalence class essentially "mirrors" the behavior of all elements in that class.

Definitions:

An ***equivalence relation*** on A is a binary relation on A that is reflexive, symmetric, and transitive.

If R is an equivalence relation on A, the ***equivalence class*** of $a \in A$ is the set $R[a] = \{b \in A \mid aRb\}$. When it is clear from context which equivalence relation is intended, the notation for the induced equivalence class can be abbreviated $[a]$.

The ***induced partition*** on a set A under an equivalence relation R is the set of equivalence classes.

Facts:

1. A nonempty relation R is an equivalence relation if and only if $R \circ R^{-1} = R$.

2. The induced partition on a set A actually is a partition of A; i.e., the equivalence classes are all nonempty, every element of A lies in some equivalence class, and two classes $[a]$ and $[b]$ are either disjoint or equal.

3. There is a one-to-one correspondence between the set of all possible equivalence relations on a set A and the set of all possible partitions of A. (Fact 2 shows how to obtain a partition from an equivalence relation. To obtain an equivalence relation from a partition of A, define R by the rule aRb if and only if a and b lie in the same element of the partition.)

4. For any set A, the coarsest partition (with only one set in the partition) of A is induced by the equivalence relation in which every pair of elements are related. The finest partition (with each set in the partition having cardinality 1) of A is induced by the equivalence relation in which no two different elements are related.

5. The set of all partitions of a set A is partially ordered under refinement (§1.2.2 and §1.4.3). This partial ordering is a lattice (§5.7).

6. To find the smallest equivalence relation containing a given relation, first take the transitive closure of the relation, then take the reflexive closure of that relation, and finally take the symmetric closure.

Examples:

1. For any function $f\colon A \to B$, define the relation a_1Ra_2 to mean that $f(a_1) = f(a_2)$. Then R is an equivalence relation. Each induced equivalence class is the inverse image $f^{-1}(b)$ of some $b \in B$.

2. Write $a \equiv b \pmod{n}$ ("a is congruent to b modulo n") when a, b and $n > 0$ are integers such that $n \mid b - a$ (n divides $b - a$). Congruence mod n is an equivalence relation on the integers.

3. The equivalence relation of congruence modulo n on the integers $\mathcal{Z}$ yields a partition with n equivalence classes: $[0] = \{kn \mid k \in \mathcal{Z}\}$, $[1] = \{1 + kn \mid k \in \mathcal{Z}\}$, $[2] = \{2 + kn \mid k \in \mathcal{Z}\}, \ldots, [n-1] = \{(n-1) + kn \mid k \in \mathcal{Z}\}$.

4. The isomorphism relation on any set of groups is an equivalence relation. (The same result holds for rings, fields, etc.) (See Chapter 5.)

5. The congruence relation for geometric objects in the plane is an equivalence relation.

6. The similarity relation for geometric objects in the plane is an equivalence relation.

1.4.3 PARTIALLY ORDERED SETS

Partial orderings extend the relationship of $\leq$ on real numbers and allow a comparison of the relative "size" of elements in various sets. They are developed in greater detail in Chapter 11.

Definitions:

A ***preorder*** on a set S is a binary relation $\leq$ on S that has the following properties for all $a, b, c \in S$:

- *reflexive*: $a \leq a$
- *transitive*: if $a \leq b$ and $b \leq c$, then $a \leq c$.

A ***partial ordering*** (or ***partial order***) on a set S is a binary relation $\leq$ on S that has the following properties for all $a, b, c \in S$:

- *reflexive*: $a \leq a$
- *antisymmetric*: if $a \leq b$ and $b \leq a$, then $a = b$
- *transitive*: if $a \leq b$ and $b \leq c$, then $a \leq c$.

Notation: The expression $c \geq b$ means that $b \leq c$. The symbols $\preceq$ and $\succeq$ are often used in place of $\leq$ and $\geq$. The expression $a < b$ (or $b > a$) means that $a \leq b$ and $a \neq b$.

A ***partially ordered set*** (or ***poset***) is a set with a partial ordering defined on it.

A ***directed ordering*** on a set S is a partial ordering that also satisfies the following property: if $a, b \in S$, then there is a $c \in S$ such that $a \leq c$ and $b \leq c$.

Note: Some authors do not require that antisymmetry hold in the definition of directed ordering.

Two elements a and b in a poset are ***comparable*** if either $a \leq b$ or $b \leq a$. Otherwise, they are ***incomparable***.

A ***totally ordered*** (or ***linearly ordered***) set is a poset in which every pair of elements are comparable.

A ***chain*** is a subset of a poset in which every pair of elements are comparable.

An ***antichain*** is a subset of a poset in which no two distinct elements are comparable.

An ***interval*** in a poset $(S, \leq)$ is a subset $[a, b] = \{x \mid x \in S, a \leq x \leq b\}$.

An element b in a poset is ***minimal*** if there exists no element c such that $c < b$.

An element b in a poset is ***maximal*** if there exists no element c such that $c > b$.

An element b in a poset S is a ***maximum element*** (or ***greatest element***) if every element c satisfies the relation $c \leq b$.

An element b in a poset S is a ***minimum element*** (or ***least element***) if every element c satisfies the relation $c \geq b$.

A ***well-ordered*** set is a poset $(S, \leq)$ in which every nonempty subset contains a minimum element.

An element b in a poset S is an ***upper bound*** for a subset $U \subseteq S$ if every element c of U satisfies the relation $c \leq b$.

An element b in a poset S is a ***lower bound*** for a subset $U \subseteq S$ if every element c of U satisfies the relation $c \geq b$.

A ***least upper bound*** for a subset U of a poset S is an upper bound b such that if c is any other upper bound for U then $c \geq b$.

A ***greatest lower bound*** for a subset U of a poset S is a lower bound b such that if c is any other lower bound for U then $c \leq b$.

A ***lattice*** is a poset in which every pair of elements, x and y, have both a least upper bound $\text{lub}(x, y)$ and a greatest lower bound $\text{glb}(x, y)$ (§5.7).

The ***Cartesian product*** of two posets $(S_1, \leq_1)$ and $(S_2, \leq_2)$ is the poset with domain $S_1 \times S_2$ and relation $\leq_1 \times \leq_2$ given by the rule $(a_1, a_2) \leq_1 \times \leq_2 (b_1, b_2)$ if and only if $a_1 \leq_1 b_1$ and $a_2 \leq_2 b_2$.

The element c ***covers*** another element b in a poset if $b < c$ and there is no element d such that $b < d < c$.

A ***Hasse diagram*** (***cover diagram***) for a poset $(S, \leq)$ is a directed graph (§11.1) whose vertices are the elements of S such that there is an arc from b to c if c covers b, all arcs are directed upward when drawing the diagram, and arrows on the arcs are omitted.

Facts:

1. R is a partial order on a set S if and only if R^{-1} is a partial order on S.

2. The only partial order that is also an equivalence relation is the relation of equality.

3. The Cartesian product of two posets, each with at least two elements, is not totally ordered.

4. In the Hasse diagram for a poset, there is a path from vertex b to vertex c if and only if $b \leq c$. (When $b = c$, it is the path of length 0.)

5. Least upper bounds and greatest lower bounds are unique, if they exist.

Examples:

1. The positive integers are partially ordered under the relation of divisibility, in which $b \leq c$ means that b divides c. In fact, they form a lattice (§5.7.1), called the *divisibility lattice*. The least upper bound of two numbers is their least common multiple, and the greatest lower bound is their greatest common divisor.

2. The set of all powers of two (or of any other positive integer) forms a chain in the divisibility lattice.

3. The set of all primes forms an antichain in the divisibility lattice.

4. The set $\mathcal{R}$ of real numbers with the usual definition of $\leq$ is a totally ordered set.

5. The set of all logical propositions on a fixed set of logical variables $p, q, r, \ldots$ is partially ordered under inverse implication, so that $B \leq A$ means that $A \to B$ is a tautology.

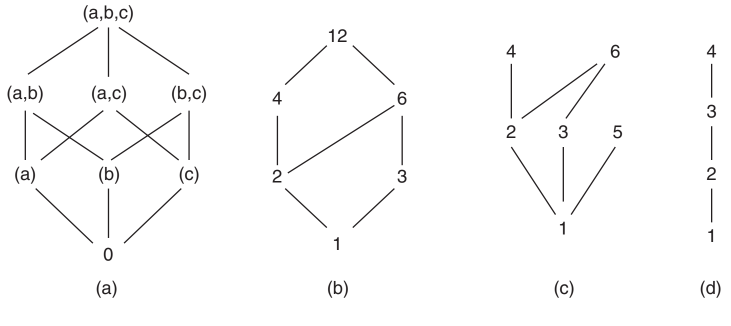
6. The complex numbers, ordered under magnitude, do *not* form a poset, because they do not satisfy the axiom of antisymmetry.

7. The set of all subsets of any set forms a lattice under the relation of subset inclusion. The least upper bound of two subsets is their union, and the greatest lower bound is their intersection. Part (a) in the following figure gives the Hasse diagram for the lattice of all subsets of $\{a, b, c\}$.

8. Part (b) of the following figure shows the Hasse diagram for the lattice of all positive integer divisors of 12.

9. Part (c) of the following figure shows the Hasse diagram for the set $\{1, 2, 3, 4, 5, 6\}$ under divisibility.

10. Part (d) of the following figure shows the Hasse diagram for the set $\{1, 2, 3, 4\}$ with the usual definition of $\leq$.



11. *Multilevel security policy*: The flow of information is often restricted by using security clearances. Documents are put into security classes, (L, C), where L is an element of a totally ordered set of authority levels (such as "unclassified", "confidential", "secret", "top secret") and C is a subset (called a "compartment") of a set of subject areas. The subject areas might consist of topics such as agriculture, Eastern Europe, economy, crime, and trade. A document on how trade affects the economic structure of Eastern Europe might be assigned to the compartment {trade, economy, Eastern Europe}. The set of security classes is made into a lattice by the rule: $(L_1, C_1) \leq (L_2, C_2)$ if and only if $L_1 \leq L_2$ and $C_1 \subseteq C_2$. Information is allowed to flow from class (L_1, C_1) to class (L_2, C_2) if and only if $(L_1, C_1) \leq (L_2, C_2)$. For example, a document with security class (secret, {trade, economy}) flows to both (top secret, {trade, economy}) and (secret, {trade, economy, Eastern Europe}), but not vice versa. This set of security classes forms a lattice (§5.7.1).

1.4.4 n-ARY RELATIONS

Definitions:

An ***n*-ary relation** on sets $A_1, A_2, \ldots, A_n$ is any subset R of $A_1 \times A_2 \times \cdots \times A_n$.

The sets A_i are called the ***domains*** of the relation and the number n is called the ***degree*** of the relation.

A ***primary key*** of an n-ary relation R on $A_1 \times A_2 \times \cdots \times A_n$ is a domain A_i such that each $a_i \in A_i$ is the ith coordinate of at most one n-tuple in R.

A ***composite key*** of an n-ary relation R on $A_1 \times A_2 \times \cdots \times A_n$ is a product of domains $A_{i_1} \times A_{i_2} \times \cdots \times A_{i_m}$ such that for each m-tuple $(a_{i_1}, a_{i_2}, \ldots, a_{i_m}) \in A_{i_1} \times A_{i_2} \times \cdots \times A_{i_m}$, there is at most one n-tuple in R that matches $(a_{i_1}, a_{i_2}, \ldots, a_{i_m})$ in coordinates $i_1, i_2, \ldots, i_m$.

The ***projection function*** $P_{i_1,i_2,\ldots,i_k} : A_1 \times A_2 \times \cdots \times A_n \to A_{i_1} \times A_{i_2} \times \cdots \times A_{i_k}$ is given by the rule

$$P_{i_1,i_2,\ldots,i_k}(a_1, a_2, \ldots, a_n) = (a_{i_1}, a_{i_2}, \ldots, a_{i_k}).$$

That is, $P_{i_1,i_2,\ldots,i_k}$ selects the elements in coordinate positions $i_1, i_2, \ldots, i_k$ from the n-tuple $(a_1, a_2, \ldots, a_n)$.

The ***join*** $J_k(R, S)$ of an m-ary relation R and an n-ary relation S, where $k \leq m$ and $k \leq n$, is a relation of degree $m + n - k$ such that

$$(a_1, \ldots, a_{m-k}, c_1, \ldots, c_k, b_1, \ldots, b_{n-k}) \in J_k(R, S)$$

if and only if

$$(a_1, \ldots, a_{m-k}, c_1, \ldots, c_k) \in R \text{ and } (c_1, \ldots, c_k, b_1, \ldots, b_{n-k}) \in S.$$

Facts:

1. An n-ary relation on sets $A_1, A_2, \ldots, A_n$ can be regarded as a function R from $A_1 \times A_2 \times \cdots \times A_n$ to the Boolean domain $\{\text{TRUE}, \text{FALSE}\}$, where $(a_1, a_2, \ldots, a_n) \in R$ if and only if $R(a_1, a_2, \ldots, a_n) = \text{TRUE}$.

2. n-ary relations are essential models in the construction of database systems.

Examples:

1. Let A_1 be the set of all men and A_2 the set of all women, in a nonpolygamous society. Let mRw mean that m and w are presently married. Then each of A_1 and A_2 is a primary key.

2. Let A_1 be the set of all telephone numbers and A_2 the set of all persons. Let nRp mean that telephone number n belongs to person p. Then A_1 is a primary key if each number is assigned to at most one person, and A_2 is a primary key if each person has at most one phone number.

3. In a conventional telephone directory, the name and address domains can form a composite key, unless there are two persons with the same name (no distinguishing middle initial or suffix such as "Jr.") at the same address.

4. Let $A = B = C = \mathcal{Z}$, and let R be the relation on $A \times B \times C$ such that $(a, b, c) \in R$ if and only if $a + b = c$. The set $A \times B$ is a composite key. There is no primary key.

5. Let $A =$ all students at a certain college, $B =$ all student ID numbers being used at the college, $C =$ all major programs at the college. Suppose a relation R is defined on $A \times B \times C$ by the rule $(a, b, c) \in R$ means student a with ID number b has major c. If each student has exactly one major and if there is a one-to-one correspondence between students and ID numbers, then A and B are each primary keys.

6. Let $A =$ all employee names at a certain corporation, $B =$ all Social Security numbers, $C =$ all departments, $D =$ all job titles, $E =$ all salary amounts, and $F =$ all calendar dates. On $A \times B \times C \times D \times E \times F \times F$ let R be the relation such that $(a, b, c, d, e, f, g) \in R$ means employee named a with Social Security number b works in department c, has job title d, earns an annual salary e, was hired on date f, and had the most recent performance review on date g. The projection $P_{1,5}$ (projection onto $A \times E$) gives a list of employees and their salaries.

1.5 PROOF TECHNIQUES

A proof is a derivation of new facts from old ones. A proof makes possible the derivation of properties of a mathematical model from its definition, or the drawing of scientific inferences based on data that have been gathered. Axioms and postulates capture all basic truths used to develop a theory. Constructing proofs is one of the principal activities of mathematicians.

Furthermore, proofs play an important role in computer science—in such areas as verification of the correctness of computer programs, verification of communications protocols, automatic reasoning systems, and logic programming.

1.5.1 RULES OF INFERENCE

Definitions:

A ***proposition*** is a declarative sentence that is unambiguously either true or false. (See §1.1.1.)

A ***theorem*** is a proposition derived as the conclusion of a valid proof from axioms and definitions.

A ***lemma*** is a theorem that is an intermediate step in the proof of a more important theorem.

A ***corollary*** is a theorem that is derived as an easy consequence of another theorem.

A ***statement form*** is a declarative sentence containing some variables and logical symbols, such that the sentence becomes a proposition if concrete values are substituted for all the free variables.

An ***argument form*** is a sequence of statement forms.

The final statement form in an argument form is called the ***conclusion*** (of the argument). The conclusion is often preceded by the word "therefore" (symbolized $\therefore$).

The statement forms preceding the conclusion in an argument form are called ***premises*** (of the argument).

If concrete values are substituted for the free variables of an argument form, an ***argument of that form*** is obtained.

An ***instantiation*** of an argument is the substitution of concrete values into all free variables of the premises and conclusion.

A ***valid argument form*** is an argument form such that in every instantiation in which all the premises are true, the conclusion is also true.

A ***rule of inference*** is an alternative name for a valid argument form, which is used when the form is frequently applied.

Facts:

1. *Substitution rule*: Any variable occurring in an argument may be replaced by an expression of the same type without affecting the validity of the argument, as long as the replacement is made everywhere the variable occurs.

2. The following table gives rules of inference for arguments with compound statements.

name	*argument form*	*name*	*argument form*
Modus ponens *(method of affirming)*	$p \to q$ p $\therefore q$	*Modus tollens* *(method of denying)*	$p \to q$ $\neg q$ $\therefore \neg p$
Hypothetical syllogism	$p \to q$ $q \to r$ $\therefore p \to r$	*Disjunctive syllogism*	$p \vee q$ $\neg p$ $\therefore q$
Disjunctive addition	p $\therefore p \vee q$	*Dilemma by cases*	$p \vee q$ $p \to r$ $q \to r$ $\therefore r$
Constructive dilemma	$p \vee r$ $p \to q$ $r \to s$ $\therefore q \vee s$	*Destructive dilemma*	$\neg q \vee \neg s$ $p \to q$ $r \to s$ $\therefore \neg p \vee \neg r$
Conjunctive addition	p q $\therefore p \wedge q$	*Conditional proof*	p $p \wedge q \to r$ $\therefore q \to r$
Conjunctive simplification	$p \wedge q$ $\therefore p$	*Rule of contradiction*	*given the contradiction c* $\neg p \to c$ $\therefore p$

3. The following table gives rules of inference for arguments with quantifiers.

name	*argument form*
Universal instantiation	$(\forall x \in D)\, Q(x)$ $\therefore Q(a)$ (a any particular element of D)
Generalizing from the generic particular	$Q(a)$ (a an arbitrarily chosen element of D) $\therefore (\forall x \in D)\, Q(x)$
Existential specification	$(\exists x \in D)\, Q(x)$ $\therefore Q(a)$ (for at least one $a \in D$)
Existential generalization	$Q(a)$ (for at least one element $a \in D$) $\therefore (\exists x \in D)\, Q(x)$

4. Substituting $R(x) \to S(x)$ in place of $Q(x)$ and z in place of x in generalizing from the generic particular gives the following inferential rule:

Universal modus ponens: $R(a) \to S(a)$ *for any particular but arbitrarily chosen* $a \in D$
$\therefore (\forall z \in D)\, [R(z) \to S(z)]$.

5. The rule of generalizing from the generic particular determines the outline of most mathematical proofs.

6. The rule of existential specification is used in deductive reasoning to give names to quantities that are known to exist but whose exact values are unknown.

7. A useful strategy for determining whether a statement is true is to first try to prove it using a variety of approaches and proof methods. If this is unsuccessful, the next step may be to try to disprove the statement, such as by trying to construct or prove the existence of a counterexample. If this does not work, the next step is to try to prove the statement again, and so on. This is one of the many ways in which many mathematicians attempt to develop new results.

Examples:

1. Suppose that D is the set of all objects in the physical universe, $P(x)$ is "x is a human being", $Q(x)$ is "x is mortal", and a is the Greek philosopher Socrates.

argument form	*an argument of that form*
$(\forall x \in D)\ [P(x) \to Q(x)]$	$\forall$ objects x, (x is a human being) → (x is mortal). (*informally*: All human beings are mortal.)
$P(a)$ (for particular $a \in D$)	Socrates is a human being.
$\therefore Q(a)$	$\therefore$Socrates is mortal.

2. The argument form shown below is invalid: there is an argument of this form (shown next to it) that has true premises and a false conclusion.

argument form	*an argument of that form*
$(\forall x \in D)\ [P(x) \to Q(x)]$	$\forall$ objects x, (x is a human being) → (x is mortal). (*informally*: All human beings are mortal.)
$Q(a)$ (for particular $a \in D$)	My cat Bunbury is mortal.
$\therefore P(a)$	$\therefore$My cat Bunbury is a human being.

In this example, D is the set of all objects in the physical universe, $P(x)$ is "x is a human being", $Q(x)$ is "x is mortal", and a is my cat Bunbury.

3. The distributive law for real numbers, $(\forall a, b, c \in \mathcal{R})[ac + bc = (a+b)c]$, implies that $2\sqrt{2} + 3\sqrt{2} = (2+3)\sqrt{2}$ (because 2, 3, and $\sqrt{2}$ are particular real numbers).

4. Since 2 is a prime number that is not odd, the rule of existential generalization implies the truth of the statement "$\exists$ a prime number n such that n is not odd".

5. To prove that the square of every even integer is even, by the rule of generalizing from the generic particular, begin by supposing that n is any particular but arbitrarily chosen even integer. The job of the proof is to deduce that n^2 is even.

6. By definition, every even integer equals twice some integer. So if at some stage of a reasoning process there is a particular even integer n, it follows from the rule of existential specification that $n = 2k$ for *some* integer k (even though the numerical values of n and k may be unknown).

1.5.2 PROOFS

Definitions:

A (***logical***) ***proof*** of a statement is a finite sequence of statements (called the ***steps*** of the proof) leading from a set of premises to the given statement. Each step of the proof must either be a premise or follow from some previous steps by a valid rule of inference.

In a ***mathematical proof***, the set of premises may contain any item of previously proved or agreed upon mathematical knowledge (definitions, axioms, theorems, etc.) as well as the specific hypotheses of the statement to be proved.

A ***direct proof*** of a statement of the form $p \to q$ is a proof that assumes p to be true and then shows that q is true.

An ***indirect proof*** of a statement of the form $p \to q$ is a proof that assumes that $\neg q$ is true and then shows that $\neg p$ is true. That is, a proof of this form is a direct proof of the contrapositive $\neg q \to \neg p$.

A ***proof by contradiction*** assumes the negation of the statement to be proved and shows that this leads to a contradiction.

Facts:

1. A useful strategy to determine if a statement of the form $(\forall x \in D)\,[P(x) \to Q(x)]$ is true or false is to imagine an element $x \in D$ that satisfies $P(x)$ and, using this assumption (and other facts), investigate whether x must also satisfy $Q(x)$. If the answer for all such x is "yes", the given statement is true and the result of the investigation is a direct proof. If it is possible to find an $x \in D$ for which $Q(x)$ is false, the statement is false and this value of x is a counterexample. If the investigation shows that is not possible to find an $x \in D$ for which $Q(x)$ is false, the given statement is true and the result of the investigation is a proof by contradiction.

2. There are many types of techniques that can be used to prove theorems. The following table describes how to approach proofs of various types of statements.

statement	*technique of proof*
$p \to q$	*Direct proof*: Assume that p is true. Use rules of inference and previously accepted axioms, definitions, theorems, and facts to deduce that q is true.
$(\forall x \in D)P(x)$	*Direct proof*: Suppose that x is an arbitrary element of D. Use rules of inference and previously accepted axioms, definitions, and facts to deduce that $P(x)$ is true.
$(\exists x \in D)P(x)$	*Constructive direct proof*: Use rules of inference and previously accepted axioms, definitions, and facts to actually find an $x \in D$ for which $P(x)$ is true. *Nonconstructive direct proof*: Deduce the existence of x from other mathematical facts without a description of how to compute it.
$(\forall x{\in}D)(\exists y{\in}E)P(x,y)$	*Constructive direct proof*: Assume that x is an arbitrary element of D. Use rules of inference and previously accepted axioms, definitions, and facts to show the existence of a $y \in E$ for which $P(x,y)$ is true, in such a way that y can be computed as a function of x. *Nonconstructive direct proof*: Assume x is an arbitrary element of D. Deduce the existence of y from other mathematical facts without a description of how to compute it.
$p \to q$	*Proof by cases*: Suppose $p \equiv p_1 \vee \cdots \vee p_k$. Prove that each conditional $p_i \to q$ is true. The basis for division into cases is the logical equivalence $[(p_1 \vee \cdots \vee p_k) \to q] \equiv [(p_1 \to q) \wedge \cdots \wedge (p_k \to q)]$.
$p \to q$	*Indirect proof or proof by contraposition*: Assume that $\neg q$ is true (that is, assume that q is false). Use rules of inference and previously accepted axioms, definitions, and facts to show that $\neg p$ is true (that is, p is false).
$p \to q$	*Proof by contradiction*: Assume that $p \to q$ is false (that is, assume that p is true and q is false). Use rules of inference and previously accepted axioms, definitions, and facts to show that a contradiction results. This means that $p \to q$ cannot be false, and hence must be true.
$(\exists x \in D)P(x)$	*Proof by contradiction*: Assume that there is no $x \in D$ for which $P(x)$ is true. Show that a contradiction results.
$(\forall x \in D)P(x)$	*Proof by contradiction*: Assume that there is some $x \in D$ for which $P(x)$ is false. Show that a contradiction results.
$p \to (q \vee r)$	*Proof of a disjunction*: Prove that one of its logical equivalences $(p \wedge \neg q) \to r$ or $(p \wedge \neg r) \to q$ is true.
$p_1, \ldots, p_k$ are equivalent	*Proof by cycle of implications*: Prove $p_1 \to p_2$, $p_2 \to p_3$, $\ldots$, $p_{k-1} \to p_k$, $p_k \to p_1$. This is equivalent to proving $(p_1 \to p_2) \wedge (p_2 \to p_3) \wedge \cdots \wedge (p_{k-1} \to p_k) \wedge (p_k \to p_1)$.

Examples:

1. In the following direct proof (see the table in Fact 2, item 2), the domain D is the set of all pairs of integers, x is (m,n), and the predicate $P(m,n)$ is "if m and n are even, then $m+n$ is even".

Theorem: For all integers m and n, if m and n are even, then $m + n$ is even.

Proof: Suppose m and n are arbitrarily chosen even integers. [$m + n$ *must be shown to be even.*]

1. $m = 2r$, $n = 2s$ for some integers r and s (by definition of even)
2. $m + n = 2r + 2s$ (by substitution)
3. $m + n = 2(r + s)$ (by factoring out the 2)
4. $r + s$ is an integer (it is a sum of two integers)
5. $\therefore$ $m + n$ is even (by definition of even)

The following partial expansion of the proof shows how some of the steps are justified by rules of inference combined with previous mathematical knowledge:

1. Every even integer equals twice some integer:
   [$\forall$ even $x \in \mathcal{Z}$ ($x = 2y$ for some $y \in \mathcal{Z}$)]
   m is a particular even integer.
   $\therefore$ $m = 2r$ for some integer r.

3. Every integer is a real number: [$\forall n \in \mathcal{Z}$ ($n \in \mathcal{R}$)]
   r and s are particular integers.
   $\therefore$ r and s are real numbers.
   The distributive law holds for real numbers: [$\forall a, b, c \in \mathcal{R}$ ($ab + ac = a(b + c)$)]
   2, r, and s are particular real numbers.
   $\therefore$ $2r + 2s = 2(r + s)$.

4. Any sum of two integers is an integer: [$\forall m, n \in \mathcal{Z}$ ($m + n \in \mathcal{Z}$)]
   r and s are particular integers.
   $\therefore$ $r + s$ is an integer.

5. Any integer that equals twice some integer is even:
   [$\forall x \in \mathcal{Z}$ (if $x = 2y$ for some $y \in \mathcal{Z}$, then x is even.)]
   $2(r + s)$ equals twice the integer $r + s$.
   $\therefore$ $2(r + s)$ is even.

2. *A constructive existence proof*:

Theorem: Given any integer n, there is an integer m with $m > n$.

Proof: Suppose that n is an integer. Let $m = n + 1$. Then m is an integer and $m > n$.

The proof is constructive because it established the existence of the desired integer m by showing that its value can be computed by adding 1 to the value of n.

3. *A nonconstructive existence proof*:

Theorem: Given a nonnegative integer n, there is always a prime number p that is greater than n.

Proof: Suppose that n is a nonnegative integer. Consider $n! + 1$. Then $n! + 1$ is divisible by some prime number p because every integer greater than 1 is divisible by a prime number, and $n! + 1 > 1$. Also, $p > n$ because when $n! + 1$ is divided by any positive integer less than or equal to n, the remainder is 1 (since any such number is a factor of $n!$).

The proof is a nonconstructive existence proof because it demonstrated the existence of the number p, but it offered no computational rule for finding it.

4. *A proof by cases*:

Theorem: For all odd integers n, the number $n^2 - 1$ is divisible by 8.

Proof: Suppose n is an odd integer. When n is divided by 4, the remainder is 0, 1, 2, or 3. Hence n has one of the four forms $4k$, $4k+1$, $4k+2$, or $4k+3$ for some integer k. But n is odd. So $n \neq 4k$ and $n \neq 4k+2$. Thus either $n = 4k+1$ or $n = 4k+3$ for some integer k.

Case 1 [$n = 4k+1$ for some integer k]: In this case $n^2 - 1 = (4k+1)^2 - 1 = 16k^2 + 8k + 1 - 1 = 16k^2 + 8k = 8(2k^2 + k)$, which is divisible by 8 because $2k^2 + k$ is an integer.

Case 2 [$n = 4k+3$ for some integer k]: In this case $n^2 - 1 = (4k+3)^2 - 1 = 16k^2 + 24k + 9 - 1 = 16k^2 + 24k + 8 = 8(2k^2 + 3k + 1)$, which is divisible by 8 because $2k^2 + 3k + 1$ is an integer.

So in either case $n^2 - 1$ is divisible by 8, and thus the given statement is proved.

5. *A proof by contraposition*:

Theorem: For all integers n, if n^2 is even, then n is even.

Proof: Suppose that n is an integer that is not even. Then when n is divided by 2 the remainder is 1, or, equivalently, $n = 2k+1$ for some integer k. By substitution, $n^2 = (2k+1)^2 = 4k^2 + 4k + 1 = 2(2k^2 + 2k) + 1$. It follows that when n^2 is divided by 2 the remainder is 1 (because $2k^2 + 2k$ is an integer). Thus, n^2 is not even.

In this proof by contraposition, a direct proof was given of the contrapositive "if n is not even, then n^2 is not even".

6. *A proof by contradiction*:

Theorem: $\sqrt{2}$ is irrational.

Proof: Suppose not; that is, suppose that $\sqrt{2}$ were a rational number. By definition of rational, there would exist integers a and b such that $\sqrt{2} = \frac{a}{b}$, or, equivalently, $2b^2 = a^2$. Now the prime factorization of the left-hand side of this equation contains an odd number of factors and that of the right-hand side contains an even number of factors (because every prime factor in an integer occurs twice in the prime factorization of the square of that integer). But this is impossible because the prime factorization of every integer is unique. This yields a contradiction, which shows that the original supposition was false. Hence $\sqrt{2}$ is irrational.

7. *A proof by cycle of implications*:

Theorem: For all positive integers a and b, the following statements are equivalent:

(1) a is a divisor of b;

(2) the greatest common divisor of a and b is a;

(3) $\lfloor \frac{b}{a} \rfloor = \frac{b}{a}$.

Proof : Let a and b be positive integers.

(1) → (2): Suppose that a is a divisor of b. Since a is also a divisor of a, a is a common divisor of a and b. But no integer greater than a is a divisor of a. So the greatest common divisor of a and b is a.

(2) → (3): Suppose that the greatest common divisor of a and b is a. Then a is a divisor of both a and b, so $b = ak$ for some integer k. Then $\frac{b}{a} = k$, an integer, and so by definition of floor, $\lfloor \frac{b}{a} \rfloor = k = \frac{b}{a}$.

(3) → (1): Suppose that $\lfloor \frac{b}{a} \rfloor = \frac{b}{a}$. Let $k = \lfloor \frac{b}{a} \rfloor$. Then $k = \lfloor \frac{b}{a} \rfloor = \frac{b}{a}$, and k is an integer by definition of floor. Multiplying the outer parts of the equality by a gives $b = ak$, so by definition of divisibility, a is a divisor of b.

8. *A proof of a disjunction*:

Theorem: For all integers a and p, if p is prime, then either p is a divisor of a, or a and p have no common factor greater than 1.

Proof: Suppose a and p are integers and p is prime, but p is not a divisor of a. Since p is prime, its only positive divisors are 1 and p. So, since p is not a divisor of a, the only possible positive common divisor of a and p is 1. Hence a and p have no common divisor greater than 1.

1.5.3 DISPROOFS

Definitions:

A ***disproof*** of a statement is a proof that the statement is false.

A ***counterexample*** to a statement of the form $(\forall x \in D)P(x)$ is an element $b \in D$ for which $P(b)$ is false.

Facts:

1. The method of disproof by counterexample is based on the following fact:

$$\neg[(\forall x \in D)\, P(x)] \;\Leftrightarrow\; (\exists x \in D)\,[\neg P(x)].$$

2. The following table describes how to give various types of disproofs.

statement	*technique of disproof*
$(\forall x{\in}D)P(x)$	*Constructive disproof by counterexample*: Exhibit a specific $a \in D$ for which $P(a)$ is false.
$(\forall x{\in}D)P(x)$	*Existence disproof*: Prove the existence of some $a \in D$ for which $P(a)$ is false.
$(\exists x{\in}D)P(x)$	Prove that there is no $a \in D$ for which $P(a)$ is true.
$(\forall x{\in}D)\,[P(x) \to Q(x)]$	Find an element $a \in D$ with $P(a)$ true and $Q(a)$ false.
$(\forall x{\in}D)(\exists y{\in}E)\,P(x,y)$	Find an element $a \in D$ with $P(a,y)$ false for every $y \in E$.
$(\exists x{\in}D)(\forall y{\in}E)\,P(x,y)$	Prove that there is no $a \in D$ for which $P(a,y)$ is true for every possible $y \in E$.

Examples:

1. The statement $(\forall a,b \in \mathcal{R})\ [\,a^2 < b^2 \to a < b\,]$ is disproved by the following counterexample: $a = 2$, $b = -3$. Then $a^2 < b^2$ (because $4 < 9$) but $a \not< b$ (because $2 \not< -3$).

2. The statement "every prime number is odd" is disproved by exhibiting the counterexample $n = 2$, since n is prime and not odd.

1.5.4 MATHEMATICAL INDUCTION

Definitions:

The ***principle of mathematical induction*** (***weak form***) is the following rule of inference for proving that all the items in a list $x_0, x_1, x_2, \ldots$ have some property $P(x)$:

$P(x_0)$ is true	*basis premise*
$(\forall k \geq 0\,)$ [if $P(x_k)$ is true, then $P(x_{k+1})$ is true]	*induction premise*
$\therefore\ (\forall n \geq 0)\,[P(x_n)$ is true].	*conclusion*

The antecedent $P(x_k)$ in the induction premise "if $P(x_k)$ is true, then $P(x_{k+1})$ is true" is called the ***induction hypothesis***.

The ***basis step*** of a proof by mathematical induction is a proof of the basis premise.

The ***induction step*** of a proof by mathematical induction is a proof of the induction premise.

The ***principle of mathematical induction*** (***strong form***) is the following rule of inference for proving that all the items in a list $x_0, x_1, x_2, \ldots$ have some property $P(x)$:

$P(x_0)$ is true	*basis premise*
$(\forall k \geq 0)$ [if $P(x_0), P(x_1), \ldots, P(x_k)$ are all true, then $P(x_{k+1})$ is true]	*(strong) induction premise*
$\therefore\ (\forall n \geq 0)\,[P(x_n)$ is true].	*conclusion*

The ***well-ordering principle for the integers*** is the following axiom: If S is a nonempty set of integers such that every element of S is greater than some fixed integer, then S contains a least element.

Facts:

1. Typically, the principle of mathematical induction is used to prove that one of the following sequences of statements is true: $P(0), P(1), P(2), \ldots$ or $P(1), P(2), P(3), \ldots$. In these cases the principle of mathematical induction has the form: if $P(0)$ is true and $P(n) \rightarrow P(n+1)$ is true for all $n \geq 0$, then $P(n)$ is true for all $n \geq 0$; or if $P(1)$ is true and $P(n) \rightarrow P(n+1)$ is true for all $n \geq 1$, then $P(n)$ is true for all $n \geq 1$.

2. If the truth of $P(n+1)$ can be obtained from the previous statement $P(n)$, the weak form of the principle of mathematical induction can be used. If the truth of $P(n+1)$ requires the use of one or more statements $P(k)$ for $k \leq n$, then the strong form should be used.

3. Mathematical induction can also be used to prove statements that can be phrased in the form "For all integers $n \geq k$, $P(n)$ is true".

4. Mathematical induction can often be used to prove summation formulas and inequalities.

5. There are alternative forms of mathematical induction, such as the following:

- if $P(0)$ and $P(1)$ are true, and if $P(n) \rightarrow P(n+2)$ is true for all $n \geq 0$, then $P(n)$ is true for all $n \geq 0$;
- if $P(0)$ and $P(1)$ are true, and if $[P(n) \wedge P(n+1)] \rightarrow P(n+2)$ is true for all $n \geq 0$, then $P(n)$ is true for all $n \geq 0$.

6. The weak form of the principle of mathematical induction, the strong form of the principle of mathematical induction, and the well-ordering principle for the integers are all regarded as axioms for the integers. This is because they cannot be derived from the usual simpler axioms used in the definition of the integers. (See the Peano definition of the natural numbers in §1.2.3.)

7. The weak form of the principle of mathematical induction, the strong form of the principle of mathematical induction, and the well-ordering principle for the integers are all equivalent. In other words, each of them can be proved from each of the others.

8. The earliest recorded use of mathematical induction occurs in 1575 in the book *Arithmeticorum Libri Duo* by Francesco Maurolico, who used the principle to prove that the sum of the first n odd positive integers is n^2.

Examples:

1. *A proof using the weak form of mathematical induction*: (In this proof, $x_0, x_1, x_2, \ldots$ is the sequence $1, 2, 3, \ldots$, and the property $P(x_n)$ is the equation $1+2+\cdots+n = \frac{n(n+1)}{2}$.)

Theorem: For all integers $n \geq 1$, $1+2+\cdots+n = \frac{n(n+1)}{2}$.

Proof:

Basis Step: For $n = 1$ the left-hand side of the formula is 1, and the right-hand side is $\frac{1(1+1)}{2}$, which is also equal to 1. Hence $P(1)$ is true.

Induction Step: Let k be an integer, $k \geq 1$, and suppose that $P(k)$ is true. That is, suppose that $1+2+\cdots+k = \frac{k(k+1)}{2}$ holds (the induction hypothesis). It must be shown that $P(k+1)$ is true: $1+2+\cdots+(k+1) = \frac{(k+1)((k+1)+1)}{2}$, or, equivalently, that $1+2+\cdots+(k+1) = \frac{(k+1)(k+2)}{2}$. But, by substitution from the induction hypothesis,

$$\begin{aligned} 1+2+\cdots+(k+1) &= (1+2+\cdots+k)+(k+1) \\ &= \tfrac{k(k+1)}{2}+(k+1) \\ &= \tfrac{(k+1)(k+2)}{2}. \end{aligned}$$

Thus, $1+2+\cdots+(k+1) = \frac{(k+1)(k+2)}{2}$ and so $P(k+1)$ is true.

2. *A proof using the weak form of mathematical induction*:

Theorem: For all integers $n \geq 4$, $2^n < n!$.

Proof:

Basis Step: For $n = 4$, $2^4 < 4!$ is true since $16 < 24$.

Induction Step: Let k be an integer, $k \geq 4$, and suppose that $2^k < k!$ is true. The following shows that $2^{k+1} < (k+1)!$ must also be true:

$$2^{k+1} = 2 \cdot 2^k < 2 \cdot k! < (k+1)k! = (k+1)!.$$

3. *A proof using the weak form of mathematical induction*:

Theorem: For all integers $n \geq 8$, n cents in postage can be made using only 3-cent and 5-cent stamps.

Proof: Let $P(n)$ be the predicate "n cents postage can be made using only 3-cent and 5-cent stamps".

Basis Step: $P(8)$ is true since 8 cents in postage can be made using one 3-cent stamp and one 5-cent stamp.

Induction Step: Let k be an integer, $k \geq 8$, and suppose that $P(k)$ is true. The following shows that $P(k+1)$ must also be true. If the pile of stamps for k cents postage has in it any 5-cent stamps, then remove one 5-cent stamp and replace it with two 3-cent stamps. If the pile for k cents postage has only 3-cent stamps, there must be at least three 3-cent stamps in the pile (since $k \neq 3$ or 6). Remove three 3-cent stamps and replace them with two 5-cent stamps. In either case, a pile of stamps for $k+1$ cents postage results.

4. *A proof using an alternative form of mathematical induction* (Fact 5):

Theorem: For all integers $n \geq 0$, $F_n < 2^n$. (F_k are Fibonacci numbers; see §3.1.2.)

Proof: Let $P(n)$ be the predicate "$F_n < 2^n$".

Basis Step: $P(0)$ and $P(1)$ are both true since $F_0 = 0 < 1 = 2^0$ and $F_1 = 1 < 2 = 2^1$.

Induction Step: Let k be an integer, $k \geq 0$, and suppose that $P(k)$ and $P(k+1)$ are true. Then $P(k+2)$ is also true: $F_{k+2} = F_k + F_{k+1} < 2^k + 2^{k+1} < 2^{k+1} + 2^{k+1} = 2 \cdot 2^{k+1} = 2^{k+2}$.

5. *A proof using the strong form of mathematical induction*:

Theorem: Every integer $n \geq 2$ is divisible by some prime number.

Proof: Let $P(n)$ be the sentence "n is divisible by some prime number".

Basis Step: Since 2 is divisible by 2 and 2 is a prime number, $P(2)$ is true.

Induction Step: Let k be an integer with $k > 2$, and suppose that $P(i)$ is true (the induction hypothesis) for all integers i with $2 \leq i < k$. That is, suppose for all integers i with $2 \leq i < k$ that i is divisible by a prime number. (*It must now be shown that k is divisible by a prime number.*)

Now either the number k is prime or k is not prime. If k is prime, then k is divisible by a prime number, namely itself. If k is not prime, then $k = a \cdot b$ where a and b are integers, with $2 \leq a < k$ and $2 \leq b < k$. By the induction hypothesis, the number a is divisible by a prime number p, and so $k = ab$ is also divisible by that prime p. Hence, regardless of whether k is prime or not, k is divisible by a prime number.

6. *A proof using the well-ordering principle*:

Theorem: Every integer $n \geq 2$ is divisible by some prime number.

Proof: Suppose, to the contrary, that there exists an integer $n \geq 2$ that is divisible by no prime number. Thus, the set S of all integers ≥ 2 that are divisible by no prime number is nonempty. Of course, no number in S is prime, since every number is divisible by itself.

By the well-ordering principle for the integers, the set S contains a least element k. Since k is not prime, there must exist integers a and b with $2 \leq a < k$ and $2 \leq b < k$, such that $k = a \cdot b$. Moreover, since k is the least element of the set S and since both a and b are smaller than k, it follows that neither a nor b is in S. Hence, the number a (in particular) must be divisible by some prime number p. But then, since a is a factor of k, the number k is also divisible by p, which contradicts the fact that k is in S. This contradiction shows that the original supposition is false, or, in other words, that the theorem is true.

7. *A proof using the well-ordering principle*:

Theorem: Every decreasing sequence of nonnegative integers is finite.

Proof: Suppose $a_1, a_2, \ldots$ is a decreasing sequence of nonnegative integers: $a_1 > a_2 > \cdots$. By the well-ordering principle, the set $\{a_1, a_2, \ldots\}$ contains a least element a_n. This number must be the last in the sequence (and hence the sequence is finite). If a_n is not the last term, then $a_{n+1} < a_n$, which contradicts the fact that a_n is the smallest element.

1.5.5 DIAGONALIZATION ARGUMENTS

Definitions:

The ***diagonal*** of an infinite list of sequences $s_1, s_2, s_3, \ldots$ is the infinite sequence whose jth element is the jth entry of sequence s_j.

A ***diagonalization proof*** is any proof that involves the diagonal of a list of sequences, or something analogous to this.

Facts:

1. A diagonalization argument can be used to prove the existence of nonrecursive functions.

2. A diagonalization argument can be used to prove that no computer algorithm can ever be developed to determine whether an arbitrary computer program, given as input with a given set of data, will terminate (*the Turing Halting Problem*).

3. A diagonalization argument can be used to prove that every mathematical theory (under certain reasonable hypotheses) will contain statements whose truth or falsity is impossible to determine within the theory (*Gödel's Incompleteness Theorem*).

Example:

1. *A diagonalization proof*:

Theorem: The set of real numbers between 0 and 1 is uncountable. (Georg Cantor, 1845–1918).

Proof: Suppose, to the contrary, that the set of real numbers between 0 and 1 is countable. The decimal representations of these numbers can be written in a list as follows:

$$\begin{gathered}0.a_{11}a_{12}a_{13}\ldots a_{1n}\ldots\\ 0.a_{21}a_{22}a_{23}\ldots a_{2n}\ldots\\ 0.a_{31}a_{32}a_{33}\ldots a_{3n}\ldots\\ \vdots\\ 0.a_{n1}a_{n2}a_{n3}\ldots a_{nn}\ldots\end{gathered}$$

From this list, construct a new decimal number $0.b_1b_2b_3\ldots b_n\ldots$ by specifying that

$$b_i = \begin{cases} 5 & \text{if } a_{ii} \neq 5 \\ 6 & \text{if } a_{ii} = 5. \end{cases}$$

For each integer $i \geq 1$, $0.b_1b_2b_3\ldots b_n\ldots$ differs from the ith number in the list in the ith decimal place, and hence $0.b_1b_2b_3\ldots b_n\ldots$ is not in the list. Consequently, no such listing of all real numbers between 0 and 1 is possible, and hence, the set of real numbers between 0 and 1 is uncountable.

1.6 AXIOMATIC PROGRAM VERIFICATION

Axiomatic program verification is used to prove that a sequence of programming instructions achieves its specified objective. Semantic axioms for the programming language constructs are used in a formal logic argument as rules of inference. Comments called *assertions*, within the sequence of instructions, provide the main details of the argument. The presently high expense of creating verified software can be justified for code that is frequently reused, where the financial benefit is otherwise adequately large, or where human life is concerned, for instance, in airline traffic control. This section presents a representative sample of axioms for typical programming language constructs.

1.6.1 ASSERTIONS AND SEMANTIC AXIOMS

The correctness of a program can be argued formally based on a set of semantic axioms that define the behavior of individual programming language constructs [Ap81], [Fl67], [Ho69]. (Some alternative proofs of correctness use denotational semantics [Sc86], [St77] or operational semantics [We72].) In addition, it is possible to synthesize code, using techniques that permit the axioms to guide the selection of appropriate instructions [Di76], [Gr13]. Code specifications and intermediate conditions are expressed in the form of program assertions.

Definitions:

An ***assertion*** is a program comment containing a logical statement that constrains the values of the computational variables. These constraints are expected to hold when execution flow reaches the location of the assertion.

A ***semantic axiom*** for a type of programming instruction is a rule of inference that prescribes the change of value of the variables of computation caused by the execution of that type of instruction.

The assertion ***false*** represents an inconsistent set of logical conditions. A computer program cannot meet such a specification.

Given two constraints A and B on computational variables, a statement that B follows from A purely for reasons of logic and/or mathematics is called a ***logical implication***.

The ***postcondition*** for an instruction or program fragment is the assertion that immediately follows it in the program.

The ***precondition*** for an instruction or program fragment is the assertion that immediately precedes it in the program.

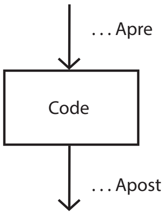
The assertion ***true*** represents the empty set of logical conditions.

Notation:

1. To say that whenever the precondition {Apre} holds, the execution of a program fragment called "Code" will cause the postcondition {Apost} to hold, the following notation styles can be used:

- *Horizontal notation:* {Apre} Code {Apost}

- *Vertical notation:* {Apre}
Code
{Apost}
- Flowgraph notation:



2. Curly braces $\{\ldots\}$ enclose assertions in generic program code. They do not denote a set.

3. Semantic axioms have a finite list of premises and a conclusion. They are represented in the following format:

$$\begin{array}{c}\{\text{Premise 1}\}\\ \vdots \\ \{\text{Premise } n\}\\ \text{- - - - - - - - - -}\\ \{\text{Conclusion}\}\end{array}$$

4. The circumstance that A logically implies B is denoted $A \Rightarrow B$.

1.6.2 NOP, ASSIGNMENT, AND SEQUENCING AXIOMS

Formal axioms of pure mathematical consequence (no operation, from a computational perspective) and of straight-line sequential flow are used as auxiliaries to verify correctness, even of sequences of simple assignment statements.

Definitions:

A ***NOP*** ("no-op") is a (possibly empty) program fragment whose execution does not alter the state of any computational variables or the sequence of flow.

The ***Axiom of NOP*** states

$$\begin{array}{ll}\{\text{Apre}\} \Rightarrow \{\text{Apost}\} & \text{Premise 1}\\ \text{- - - - - - - - - - - - - -} & \\ \{\text{Apre}\}\ \text{NOP}\ \{\text{Apost}\} & \text{Conclusion}\end{array}$$

Note: The Axiom of NOP is frequently applied to empty program fragments in order to facilitate a clear logical argument.

An ***assignment instruction*** $X := E$; means that the variable X is to be assigned the value of the expression E.

In a logical assertion $A(X)$ with possible instances of the program variable X, the ***result of replacing each instance*** of X in A by the program expression E is denoted $A(X \leftarrow E)$.

The ***Axiom of Assignment*** states

{true}	No premises
- - - - - - - - - - - - - -	
$\{A(X \leftarrow E)\}X := E; \{A(X)\}$	Conclusion

The following ***Axiom of Sequence*** provides that two consecutive instructions in the program code are executed one immediately after the other:

{Apre} Code1 {Amid}	Premise 1
{Amid} Code2 {Apost}	Premise 2
- - - - - - - - - - - - - - - -	
{Apre} Code1, Code2 {Apost}	Conclusion

(Commas are used as separators in program code.)

Examples:

1. *Example of NOP*: Suppose that X is a numeric program variable.

$\{X = 3\} \Rightarrow \{X > 0\}$	mathematical fact
- - - - - - - - - - - - - - -	
$\{X = 3\}$ NOP $\{X > 0\}$	by Axiom of NOP

2. Suppose that X and Y are integer-type program variables. The Axiom of Assignment alone implies correctness of all the following examples:

(a) $\{X = 4\} \quad X := X * 2; \quad \{X = 8\}$
$A(X)$ is $\{X = 8\}$; E is $X * 2$; $A(X \leftarrow E)$ is $\{X * 2 = 8\}$, which is equivalent to $\{X = 4\}$.

(b) {true} X := 2; $\{X = 2\}$
$A(X)$ is $\{X = 2\}$; E is 2; $A(X \leftarrow E)$ is $\{2 = 2\}$, which is equivalent to {true}.

(c) $\{(-9 < X) \wedge (X < 0)\} \quad Y := X; \quad \{(-9 < Y) \wedge (Y < 0)\}$
$A(Y)$ is $\{(-9 < Y) \wedge (Y < 0)\}$; E is X; $A(Y \leftarrow E)$ is $\{(-9 < X) \wedge (X < 0)\}$.

(d) $\{Y = 1\} \quad X := 0; \quad \{Y = 1\}$
$A(X)$ is $\{Y = 1\}$; E is 0; $A(X \leftarrow E)$ is $\{Y = 1\}$.

(e) {false} X := 8; $\{X = 2\}$
$A(X)$ is $\{X = 2\}$; E is 8; $A(X \leftarrow E)$ is $\{8 = 2\}$, which is equivalent to {false}.

3. *Examples of sequence*:

(a) $\{X = 1\}\ X := X + 1;\ \{X > 0\}$

i.	$\{X = 1\} \Rightarrow \{X > -1\}$	mathematics
ii.	$\{X = 1\}\ NOP\ \{X > -1\}$	Axiom of NOP
iii.	$\{X > -1\}\ X := X + 1;\ \{X > 0\}$	Axiom of Assignment
iv.	$\{X = 1\}\ NOP,\ X := X + 1;\ \{X > 0\}$	Axiom of Sequence ii, iii
v.	$\{X = 1\}\ X := X + 1;\ \{X > 0\}$	definition of NOP.

(b) $\{Y = a\ \wedge\ X = b\}\ Z := Y;\ Y := X;\ X := Z;\ \{X = a\ \wedge\ Y = b\}$

i.	$\{Y = a\ \wedge\ X = b\}\ Z := Y;\ \{Z = a\ \wedge\ X = b\}$	Axiom of Assignment
ii.	$\{Z = a\ \wedge\ X = b\}\ Y := X;\ \{Z = a\ \wedge\ Y = b\}$	Axiom of Assignment
iii.	$\{Y = a\ \wedge\ X = b\}\ Z := Y,\ Y := X,$ $\{Z = a\ \wedge\ Y = b\}$	Axiom of Sequence i, ii
iv.	$\{Z = a\ \wedge\ Y = b\}\ X := Z;\ \{X = a\ \wedge\ Y = b\}$	Axiom of Assignment
v.	$\{Y = a\ \wedge\ X = b\}\ Z := Y,\ Y := X,\ X := Z,$ $\{X = a\ \wedge\ Y = b\}$	Axiom of Sequence iii, iv.

1.6.3 AXIOMS FOR CONDITIONAL EXECUTION CONSTRUCTS

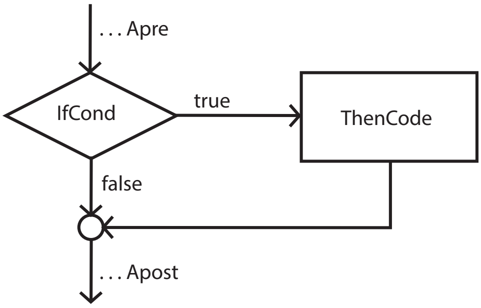
Definitions:

A ***conditional assignment construct*** is any type of program instruction containing a logical condition and an imperative clause such that the imperative clause is to be executed if and only if the logical condition is true. Some types of conditional assignment contain more than one logical condition and more than one imperative clause.

An ***if-then*** instruction ***if IfCond then ThenCode*** has one logical condition (which follows the keyword if) and one imperative clause (which follows the keyword then).

The ***Axiom of If-then*** states

$$\begin{array}{ll} \{\text{Apre} \wedge \text{IfCond}\}\ \text{ThenCode}\ \{\text{Apost}\} & \text{Premise 1} \\ \{\text{Apre} \wedge \neg\text{IfCond}\} \Rightarrow \{\text{Apost}\} & \text{Premise 2} \\ \text{- -} & \\ \{\text{Apre}\}\ \underline{\text{if}}\ \text{IfCond}\ \underline{\text{then}}\ \text{ThenCode}\ \{\text{Apost}\} & \text{Conclusion} \end{array}$$



An ***if-then-else*** instruction ***if IfCond then ThenCode else ElseCode*** has one logical condition, which follows the keyword if, and two imperative clauses, one after the keyword then, and the other after the keyword else.

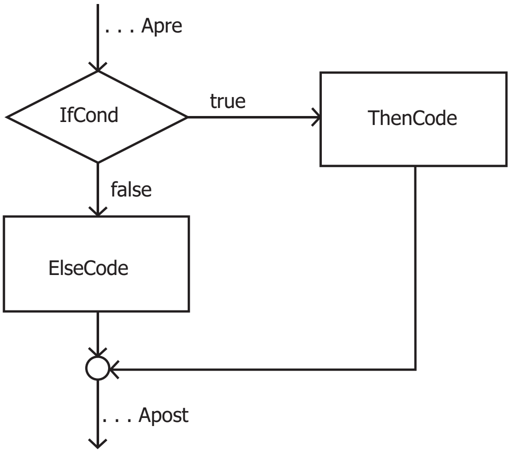
The ***Axiom of If-then-else*** states

$$\begin{array}{ll} \{\text{Apre} \wedge \text{IfCond}\}\ \text{ThenCode}\ \{\text{Apost}\} & \text{Premise 1} \\ \{\text{Apre} \wedge \neg\text{IfCond}\}\ \text{ElseCode}\ \{\text{Apost}\} & \text{Premise 2} \\ \text{- -} & \\ \{\text{Apre}\}\ \underline{\text{if}}\ \text{IfCond}\ \underline{\text{then}}\ \text{ThenCode}\ \underline{\text{else}}\ \text{ElseCode}\ \{\text{Apost}\} & \text{Conclusion} \end{array}$$

Examples:

1. *If-then*:

$\{\text{true}\}\ \underline{\text{if}}\ X = 3\ \underline{\text{then}}\ Y := X;\ \{X = 3 \to Y = 3\}$



i. $\{X = 3\}\ Y := X;\ \{X = 3\ \wedge\ Y = 3\}$ Axiom of Assignment

ii. $\{X = 3\ \wedge\ Y = 3\}\ NOP\ \{(X = 3) \rightarrow (Y = 3)\}$ Axiom of NOP

(Step ii uses a logic fact: $p \wedge q \Rightarrow p \rightarrow q$)

iii. $\{X = 3\}\ Y := X; \{X = 3 \rightarrow Y = 3\}$ Axiom of Sequence i, ii

(Step iii establishes Premise 1 for Axiom of If-then)

iv. $\{\neg(X = 3)\} \Rightarrow \{X = 3 \rightarrow Y = 3\}$ Logic fact

(Step iv establishes Premise 2 for Axiom of If-then)

v. $\{\text{true}\}\ \underline{\text{if}}\ X = 3\ \underline{\text{then}}\ Y := X;\ \{X = 3 \rightarrow Y = 3\}$ Axiom of If-then iii, iv.

2. *If-then-else*:

$\{X > 0\}$

$\quad\underline{\text{if}}\ (X > Y)\ \underline{\text{then}}\ M := X;\ \underline{\text{else}}\ M := Y;$

$\{(X > 0) \wedge (X > Y \rightarrow M = X) \wedge (X \leq Y \rightarrow M = Y)\}$

i. $\{X > 0\ \wedge\ X > Y\}\ M := X;\ \{X > 0\ \wedge\ (X > Y \rightarrow M = X)\ \wedge\ (X \leq Y \rightarrow M = Y)\}$

by Axiom of Assignment and Axiom of NOP (establishes Premise 1)

ii. $\{X > 0\ \wedge\ \neg(X > Y)\}\ M := Y;\ \{X > 0\ \wedge\ (X > Y \rightarrow M = X)\ \wedge\ (X \leq Y \rightarrow M = Y)\}$

by Axiom of Assignment and Axiom of NOP (establishes Premise 2)

iii. Conclusion now follows from Axiom of If-then-else.

1.6.4 AXIOMS FOR LOOP CONSTRUCTS

Definitions:

A ***while-loop*** instruction ***while WhileCond do LoopBody*** has one logical condition called the ***while-condition***, which follows the keyword while, and a sequence of instructions called the ***loop-body***. At the outset of execution, the while condition is tested for its truth value. If it is true, then the loop body is executed. This two-step process of test and execute continues until the while condition becomes false, after which the flow of execution passes to whatever program instruction follows the while-loop.

A loop is ***weakly correct*** if whenever the precondition is satisfied at the outset of execution and the loop is executed to termination, the resulting computational state satisfies the postcondition.

A loop is ***strongly correct*** if it is weakly correct and if whenever the precondition is satisfied at the outset of execution, the computation terminates.

The ***Axiom of While*** defines weak correctness of a while-loop (i.e., the axiom ignores the possibility of an infinite loop) in terms of a logical condition called the ***loop invariant*** denoted "LoopInv" satisfying the following condition:

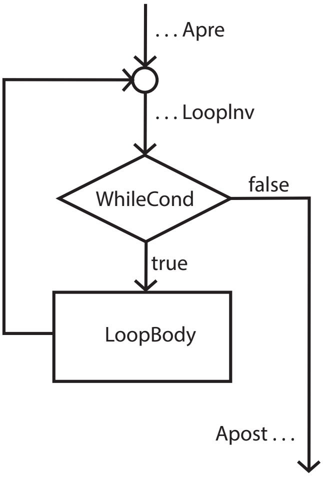
$\{\text{Apre}\} \Rightarrow \{\text{LoopInv}\}$ "Initialization" Premise

$\{\text{LoopInv} \wedge \text{WhileCond}\}\ \text{LoopBody}\ \{\text{LoopInv}\}$ "Preservation" Premise

$\{\text{LoopInv} \wedge \neg\text{WhileCond}\} \Rightarrow \{\text{Apost}\}$ "Finalization" Premise

- -

$\{\text{Apre}\}$ <u>while</u> $\{\text{LoopInv}\}$ WhileCond <u>do</u> LoopBody $\{\text{Apost}\}$ Conclusion



Example:

1. Suppose that J, N, and P are integer-type program variables.

```
{Apre : $J = 0 \ \wedge \ P = 1 \ \wedge \ N \geq 0$}
while {LoopInv : $P = 2^J \ \wedge \ J \leq N$} ($J < N$) do
    $P := P * 2$;
    $J := J + 1$;
endwhile
{Apost : $P = 2^N$}
```

i. $\{\text{Apre} : J = 0 \ \wedge \ P = 1 \ \wedge \ N \geq 0\} \Rightarrow \{\text{LoopInv} : P = 2^J \ \wedge \ J \leq N\}$

Initialization Premise trivially true by mathematics

ii. $\{\text{LoopInv} \wedge \text{WhileCond} : \ (P = 2^J \ \wedge \ J \leq N) \ \wedge \ (J < N)\}$

$P := P * 2;$

$J := J + 1;$

$\{\text{LoopInv} : \ P = 2^J \ \wedge \ J \leq N\}$

Preservation Premise proved by using Axiom of Assignment twice and Axiom of Sequence

iii. $\{\text{LoopInv} \wedge \neg\text{WhileCond} : (P = 2^J \wedge J \leq N) \wedge \neg(J < N)\} \Rightarrow \{\text{Apost} : P = 2^N\}$

Finalization Premise provable by mathematics

iv. Conclusion now follows from Axiom of While.

Fact:

1. Proof of termination of a loop is usually achieved by mathematical induction.

1.6.5 AXIOMS FOR SUBPROGRAM CONSTRUCTS

The parameterless procedure is the simplest subprogram construct. Procedures with parameters and functional subprograms have somewhat more complicated semantic axioms.

Definitions:

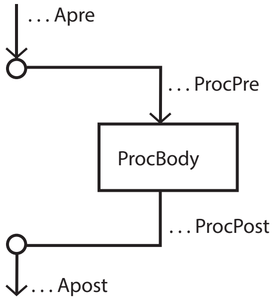
A ***procedure*** is a sequence of instructions that lies outside the main sequence of instructions in a program. It consists of a ***procedure name***, followed by a ***procedure body***.

A ***call*** instruction ***call ProcName*** is executed by transferring control to the first executable instruction of the procedure ProcName.

A ***return*** instruction causes a procedure to transfer control to the executable instruction immediately following the most recently executed call to that procedure. An implicit return is executed after the last instruction in the procedure body is executed. It is good programming style to put a *return* there.

In the following ***Axiom of Procedure*** (**parameterless**), *Apre* and *Apost* are the precondition and postcondition of the instruction *call ProcName*; *ProcPre* and *ProcPost* are the precondition and postcondition of the procedure whose name is *ProcName*.

$$\begin{array}{ll}
\{\text{Apre}\} \Rightarrow \{\text{ProcPre}\} & \text{“Call” Premise} \\
\{\text{ProcPre}\}\ \text{ProcBody}\ \{\text{ProcPost}\} & \text{“Body” Premise} \\
\{\text{ProcPost}\} \Rightarrow \{\text{Apost}\} & \text{“Return” Premise} \\
\hline
\{\text{Apre}\}\ \underline{\text{call}}\ \text{ProcName};\ \{\text{Apost}\} & \text{Conclusion}
\end{array}$$



1.7 LOGIC-BASED COMPUTER PROGRAMMING PARADIGMS

Mathematical logic is the basis for several different computer software paradigms. These include logic programming, fuzzy reasoning, production systems, artificial intelligence, and expert systems.

1.7.1 LOGIC PROGRAMMING

A computer program in the imperative paradigm (familiar in languages like C, BASIC, FORTRAN, and ALGOL) is a list of instructions that describes a precise sequence of actions that a computer should perform. To initiate a computation, one supplies the iterative program plus specific input data to the computer. *Logic programming* provides an alternative paradigm in which a program is a list of “clauses”, written in predicate logic, that describe an allowed range of behavior for the computer. To initiate a computation, the computer is supplied with the logic program plus another clause called a “goal”. The aim of the computation is to establish that the goal is a logical consequence of the clauses constituting the logic program. The computer simplifies the goal by executing the program repeatedly until the goal becomes empty, or until it cannot be further simplified.

Definitions:

A ***term*** in a domain S is either a fixed element of S or an S-valued variable.

An ***n-ary predicate*** on a set S is a function $P\colon S^n \to \{T, F\}$.

An ***atomic formula*** (or ***atom***) is an expression of the form $P(t_1, \ldots, t_n)$, where $n \geq 0$, P is an n-ary predicate, and $t_1, \ldots, t_n$ are terms.

A ***formula*** is a logical expression constructed from atoms with conjunctions, disjunctions, and negations, possibly with some logical quantifiers.

A ***substitution*** for a formula is a finite set of the form $\{v_1/t_1, \ldots, v_n/t_n\}$, where each v_i is a distinct variable, and each t_i is a term distinct from v_i.

The ***instance*** of a formula ψ using the substitution $\theta = \{v_1/t_1, \ldots, v_n/t_n\}$ is the formula obtained from ψ by simultaneously replacing each occurrence of the variable v_i in ψ by the term t_i. The resulting formula is denoted by $\psi\theta$.

A ***closed formula*** in logic programming is a program without any free variables.

A ***ground formula*** is a formula without any variables at all.

A ***clause*** is a formula of the form $\forall x_1 \ldots \forall x_s (A_1 \vee \cdots \vee A_n \leftarrow B_1 \wedge \cdots \wedge B_m)$ with no free variables, where $s, n, m \geq 0$, and A’s and B’s are atoms. In logic programming, such a clause may be denoted by $A_1, \ldots, A_n \leftarrow B_1, \ldots, B_m$.

The ***head*** of a clause $A_1, \ldots, A_n \leftarrow B_1, \ldots, B_m$ is the sequence $A_1, \ldots, A_n$.

The ***body*** of a clause $A_1, \ldots, A_n \leftarrow B_1, \ldots, B_m$ is the sequence $B_1, \ldots, B_m$.

A ***definite clause*** is a clause of the form $A \leftarrow B_1, \ldots, B_m$ or $\leftarrow B_1, \ldots, B_m$, which contains at most one atom in its head.

An ***indefinite clause*** is a clause that is not definite.

A ***logic program*** is a finite sequence of definite clauses.

A ***goal*** is a definite clause $\leftarrow B_1, \ldots, B_m$ whose head is empty. (Prescribing a goal for a logic program P tells the computer to derive an instance of that goal by manipulating the logical clauses in P.)

An ***answer*** to a goal G for a logic program P is a substitution θ such that $G\theta$ is a logical consequence of P.

A ***definite answer*** to a goal G for a logic program P is an answer in which every variable is substituted by a constant.

Facts:

1. A definite clause $A \leftarrow B_1, \ldots, B_m$ represents the following logical constructs:

If every B_i is true, then A is also true;
Statement A can be proved by proving every B_i.

2. *Definite answer property*: If a goal G for a logic program P has an answer, then it has a definite answer.

3. The definite answer property does not hold for indefinite clauses. For example, although $G = \exists x Q(x)$ is a logical consequence of $P = \{Q(a), Q(b) \leftarrow\}$, no ground instance of G is a logical consequence of P.

4. Logic programming is Turing-complete (§17.5); i.e., any computable function can be represented using a logic program.

5. Building on the work of logician J. Alan Robinson in 1965, computer scientists Robert Kowalski and Alain Colmerauer of Imperial College and the University of Marseille-Aix, respectively, in 1972 independently developed the programming language PROLOG (PROgramming in LOGic) based on a special subset of predicate logic.

6. The first PROLOG interpreter was implemented in ALGOL-W in 1972 at the University of Marseille-Aix. Since then, several variants of PROLOG have been introduced, implemented, and used in practical applications. The basic paradigm behind all these languages is called Logic Programming.

7. In PROLOG, the relation "is" means equality.

Examples:

1. The following three clauses are definite:

$$P \leftarrow Q, R \qquad P \leftarrow \qquad \leftarrow Q, R.$$

2. The clause $P, S \leftarrow Q, R$ is indefinite.

3. The substitution $\{X/a, Y/b\}$ for the atom $P(X, Y, Z)$ yields the instance $P(a, b, Z)$.

4. The goal $\leftarrow P$ to the program $\{P \leftarrow\}$ has a single answer, given by the empty substitution. This means the goal can be achieved.

5. The goal $\leftarrow P$ to the program $\{Q \leftarrow\}$ has no answer. This means it cannot be derived from that program.

6. The logic program consisting of the following two definite clauses P1 and P2 computes a complete list of the pairs of vertices in an arbitrary graph that have a path joining them:

P1. $\text{path}(V, V) \leftarrow$
P2. $\text{path}(U, V) \leftarrow \text{path}(U, W),\ \text{edge}(W, V)$

Definite clauses P3 and P4 comprise a representation of a graph with nodes 1, 2, and 3, and edges $(1, 2)$ and $(2, 3)$:

P3. edge(1,2) ←
P4. edge(2,3) ←

The goal G represents a query asking for a complete list of the pairs of vertices in an arbitrary graph that have a path joining them:

G. ← path(Y, Z)

There are three distinct answers of the goal G to the logic program consisting of definite clauses P1 to P4, corresponding to the paths $(1, 2)$, $(1, 2, 3)$, and $(2, 3)$, respectively:

A1. $\{Y/1, Z/2\}$
A2. $\{Y/1, Z/3\}$
A3. $\{Y/2, Z/3\}$

7. The following logic program computes the Fibonacci sequence $0, 1, 1, 2, 3, 5, 8, 13, \ldots,$ where the predicate $fib(N, X)$ is true if X is the Nth number in the Fibonacci sequence:

$fib(0, 0) \leftarrow$
$fib(1, 1) \leftarrow$
$fib(N, X + Y) \leftarrow N > 1, fib(N - 1, X), fib(N - 2, Y)$

The goal "$\leftarrow fib(6, X)$" is answered $\{X/8\}$, the goal "$\leftarrow fib(X, 8)$" is answered $\{X/6\}$, and the goal "$\leftarrow fib(N, X)$" has the following infinite sequence of answers:

$\{N/0, X/0\}$
$\{N/1, X/1\}$
$\{N/2, X/1\}$
⋮

8. Consider the problem of finding an assignment of digits (integers $0, 1, \ldots, 9$) to letters such that adding two given words produces the third given word, as in this example:

$$\begin{array}{ccccc} & S & E & N & D \\ + & M & O & R & E \\ \hline M & O & N & E & Y \end{array}$$

One solution to this particular puzzle is given by the following assignment:

$$D = 0,\ E = 0,\ M = 1,\ N = 0,\ O = 0,\ R = 0,\ S = 9,\ Y = 0.$$

The following PROLOG program solves all such puzzles:

$between(X, X, Z) \leftarrow X < Z.$
$between(X, Y, Z) \leftarrow between(K, Y, Z), X$ is $K - 1$.
$val([\,], 0) \leftarrow.$
$val([X|Y], A) \leftarrow val(Y, B),\ between(0, X, 9),\ A$ is $10 * B + X$.
$solve(X, Y, Z) \leftarrow val(X, A),\ val(Y, B),\ val(Z, C),\ C$ is $A + B$.

The specific example given above is captured by the following goal:

$\leftarrow solve([D, N, E, S], [E, R, O, M], [Y, E, N, O, M]).$

The predicate $between(X, Y, Z)$ means $X \leq Y \leq Z$. The predicate $val(L, N)$ means that the number N is the value of L, where L is the kind of list of letters that occurs on a line of these puzzles. The notation $[X|L]$ means the list obtained by writing list L after item X. The predicate $solve(X, Y, Z)$ means that the value of list Z equals the sum of the values of list X and list Y.

This example illustrates the ease of writing logic programs for some problems where conventional imperative programs are more difficult to write.

1.7.2 FUZZY SETS AND LOGIC

Fuzzy set theory and fuzzy logic are used to model imprecise meanings, such as "tall", that are not easily represented by predicate logic. In particular, instead of assigning either "true" or "false" to the statement "John is tall", fuzzy logic assigns a real number between 0 and 1 that indicates the degree of "tallness" of John. Fuzzy set theory assigns a real number between 0 and 1 to John that indicates the extent to which he is a member of the set of tall people. See [Ka86], [Ka92], [KaLa94], [YaFi94], [YaZa94], [Za65], [Zi01].

Definitions:

A ***fuzzy set*** $F = (X, \mu)$ consists of a set X (the ***domain***) and a ***membership function*** $\mu\colon X \to [0, 1]$. Sometimes the set is written $\{\, (x, \mu(x)) \mid x \in X \,\}$ or $\{\, \mu(x)\, x \mid x \in X \,\}$.

The ***fuzzy intersection*** of fuzzy sets (A, μ_A) and (B, μ_B) is the fuzzy set $A \cap B$ with domain $A \cap B$ and membership function $\mu_{A\cap B}(x) = \min(\mu_A(x), \mu_B(x))$.

The ***fuzzy union*** of fuzzy sets (A, μ_A) and (B, μ_B) is the fuzzy set $A \cup B$ with domain $A \cup B$ and membership function $\mu_{A\cup B}(x) = \max(\mu_A(x), \mu_B(x))$.

The ***fuzzy complement*** of the fuzzy set (A, μ) is the fuzzy set $\neg A$ or $\overline{A}$ with domain A and membership function $\mu_{\overline{A}}(x) = 1 - \mu(x)$.

The ***nth constructor*** $con(\mu, n)$ of a membership function μ is the function μ^n. That is, $con(\mu, n)(x) = (\mu(x))^n$.

The ***nth dilutor*** $dil(\mu, n)$ of a membership function μ is the function $\mu^{1/n}$. That is, $dil(\mu, n)(x) = (\mu(x))^{1/n}$.

A ***T-norm operator*** is a function $f\colon [0, 1] \times [0, 1] \to [0, 1]$ with the following properties:

- $f(x, y) = f(y, x)$ *commutativity*
- $f(f(x, y), z) = f(x, f(y, z))$ *associativity*
- if $x \leq v$ and $y \leq w$, then $f(x, y) \leq f(v, w)$ *monotonicity*
- $f(a, 1) = a$. 1 *is a unit element*

The ***fuzzy intersection*** $A \cap_f B$ of fuzzy sets (A, μ_A) and (B, μ_B) ***relative to the T-norm operator*** f is the fuzzy set with domain $A \cap B$ and membership function $\mu_{A\cap_f B}(x) = f(\mu_A(x), \mu_B(x))$.

An ***S-norm operator*** is a function $f\colon [0, 1] \times [0, 1] \to [0, 1]$ with the following properties:

- $f(x, y) = f(y, x)$ *commutativity*
- $f(f(x, y), z) = f(x, f(y, z))$ *associativity*
- if $x \leq v$ and $y \leq w$, then $f(x, y) \leq f(v, w)$ *monotonicity*
- $f(a, 1) = 1$.

The ***fuzzy union*** $A \cup_f B$ of fuzzy sets (A, μ_A) and (B, μ_B) ***relative to the S-norm operator*** f is the fuzzy set with domain $A \cup B$ and membership function $\mu_{A \cup_f B}(x) = f(\mu_A(x), \mu_B(x))$.

A ***complement operator*** is a function $f\colon [0,1] \to [0,1]$ with the following properties:

- $f(0) = 1$
- if $x < y$ then $f(x) > f(y)$
- $f(f(x)) = x$.

The ***fuzzy complement*** $\neg_f A$ of the fuzzy set (A, μ) ***relative to the complement operator*** f is the fuzzy set with domain A and membership function $\mu_{\neg_f}(x) = f(\mu(x))$.

A ***fuzzy system*** consists of a base collection of fuzzy sets, intersections, unions, complements, and implications.

A ***hedge*** is a monadic operator corresponding to linguistic adjectives such as "very", "about", "somewhat", or "quite" that modify membership functions.

A ***two-valued logic*** is a logic where each statement has exactly one of the two values: true or false.

A ***multi-valued logic*** (***n-valued logic***) is a logic with a set of n (≥ 2) truth values; i.e., there is a set of n numbers $v_1, v_2, \ldots, v_n \in [0,1]$ such that every statement has exactly one truth value v_i.

Fuzzy logic is the study of statements where each statement has assigned to it a truth value in the interval $[0,1]$ that indicates the extent to which the statement is true.

If statements p and q have truth values v_1 and v_2 respectively, the ***truth value*** of $p \vee q$ is $\max(v_1, v_2)$, the truth value of $p \wedge q$ is $\min(v_1, v_2)$, and the truth value of $\neg p$ is $1 - v_1$.

Facts:

1. Fuzzy set theory and fuzzy logic were developed by Lofti Zadeh in 1965.

2. Fuzzy set theory and fuzzy logic are parallel concepts: given a predicate $P(x)$, the fuzzy truth value of the statement $P(a)$ is the fuzzy set value assigned to a as an element of $\{\, x \mid P(x) \,\}$.

3. The usual minimum function $\min(x, y)$ is a T-norm. The usual real maximum function $\max(x, y)$ is an S-norm. The function $c(x) = 1 - x$ is a complement operator.

4. Several other kinds of T-norms, S-norms, and complement operators have been defined.

5. The words "T-norm" and "S-norm" come from multi-valued logics.

6. The only difference between T-norms and S-norms is that the T-norm specifies $f(a, 1) = a$, whereas the S-norm specifies $f(a, 1) = 1$.

7. Several standard classes of membership functions have been defined, including step, sigmoid, and bell functions.

8. Constructors and dilutors of membership functions are also membership functions.

9. The large number of practical applications of fuzzy set theory can generally be divided into three types: machine systems, human-based systems, human-machine systems. Some of these applications are based on fuzzy set theory alone and some on a variety of hybrid configurations involving neurofuzzy approaches, or in combination with neural networks, genetic algorithms, or case-based reasoning.

10. The first fuzzy expert system that set a trend in practical fuzzy thinking was the design of a cement kiln called Linkman, produced by Blue Circle Cement and SIRA in Denmark in the early 1980s. The system incorporates the experience of a human operator in a cement production facility.

11. The Sendai Subway Automatic Train Operations Controller was designed by Hitachi in Japan. In that system, speed control during cruising, braking control near station zones, and switching of control are determined by fuzzy IF-THEN rules that process sensor measurements and consider factors related to travelers' comfort and safety. In operation since 1986, this most celebrated application encouraged many applications based on fuzzy set controllers in the areas of home appliances (refrigerators, vacuum cleaners, washers, dryers, rice cookers, air conditioners, shavers, blood-pressure measuring devices), video cameras (including fuzzy automatic focusing, automatic exposure, automatic white balancing, image stabilization), automotive (fuzzy cruise control, fuel injection, transmission and brake systems), robotics, and aerospace.

12. Applications to finance started with the Yamaichi Fuzzy Fund, which is a fuzzy trading system. This was soon followed by a variety of financial applications world-wide.

13. Research activities will soon result in commercial products related to the use of fuzzy set theory in the areas of audio and video data compression (such as HDTV), robotic arm movement control, computer vision, coordination of visual sensors with mechanical motion, aviation (such as unmanned platforms), and telecommunication.

14. *Current status*: Most applications of fuzzy sets and logic are directly related to structured numerical model-free estimators. Presently, most applications are designed with linguistic variables, where proper levels of granularity are being used in the evaluations of those variables, expressing the ambiguity and subjectivity in human thinking. Fuzzy systems capture expert knowledge and through the processing of fuzzy IF-THEN rules are capable of processing knowledge combining the antecedents of each fuzzy rule, calculating the conclusions, and aggregating them to the final decision.

15. One way to model *fuzzy implication* $A \to B$ is to define $A \to B$ as $\neg_c A \cup_f B$ relative to some complement operator c and to some S-norm operator f. Several other ways have also been considered.

16. A fuzzy system is used computationally to control the behavior of an external system.

17. Large fuzzy systems have been used in specifying complex real-world control systems. The success of such systems depends crucially on the specific engineering parameters. The correct values of these parameters are usually obtained by trial-and-readjustment.

18. A two-valued logic is a logic that assumes the law of the excluded middle: $p \vee \neg p$ is a tautology.

19. Every n-valued logic is a fuzzy logic.

Examples:

1. A committee consisting of five people met ten times during the past year. Person A attended 7 meetings, B attended all 10 meetings, C attended 6 meetings, D attended no meetings, and E attended 9 meetings. The set of committee members can be described by the following fuzzy set that reflects the degree to which each of the members attended meetings, using the function μ: $\{A, B, C, D, E\} \to [0, 1]$ with the rule $\mu(x) = \frac{1}{10}$(number of meetings attended):

$$\{(A, 0.7), (B, 1.0), (C, 0.6), (D, 0.0), (E, 0.9)\},$$

which can also be written as

$$\{0.7A, 1.0B, 0.6C, 0.0D, 0.9E\}.$$

Person B would be considered a “full” member and person D a “nonmember”.

2. Four people are rated on amount of activity in a political party, yielding the fuzzy set

$$P_1 = \{0.8A, 0.45B, 0.1C, 0.75D\},$$

and based on their degree of conservatism in their political beliefs, as

$$P_2 = \{0.6A, 0.85B, 0.7C, 0.35D\}.$$

The fuzzy union of the sets is

$$P_1 \cup P_2 = \{0.8A, 0.85B, 0.7C, 0.75D\},$$

the fuzzy intersection is

$$P_1 \cap P_2 = \{0.6A, 0.45B, 0.1C, 0.35D\}$$

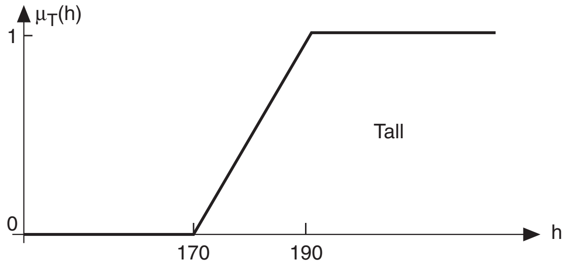
and the fuzzy complement of P_1 (measurement of political inactivity) is

$$\overline{P_1} = \{0.2A, 0.55B, 0.9C, 0.25D\}.$$

3. In the fuzzy set with domain T and membership function

$$\mu_T(h) = \begin{cases} 0 & \text{if } h \le 170 \\ \frac{h-170}{20} & \text{if } 170 < h < 190 \\ 1 & \text{otherwise} \end{cases}$$

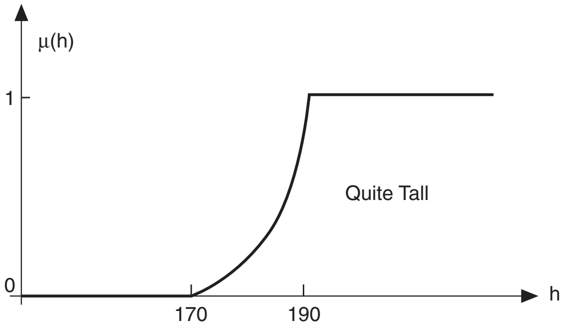
the number 160 is not a member, the number 195 is a member, and the membership of 182 is 0.6. The graph of μ_T is given in the following figure.

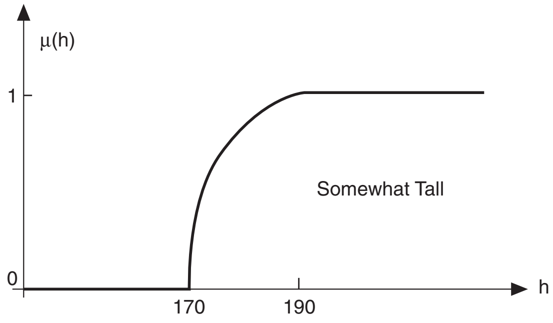


4. The fuzzy set (T, μ_T) of Example 3 can be used to define the fuzzy set “Tall” $=$ (H, μ_H) of tall people, by the rule $\mu_H(x) = \mu_T(height(x))$ where $height(x)$ is the height of person x calibrated in centimeters.

5. The second constructor $con(\mu_H, 2)$ of the fuzzy set “Tall” can be used to define a fuzzy set “Quite tall”, whose graph is given in the following figure.

6. The second dilutor $dil(\mu_H, 2)$ of the fuzzy set “Tall” defines the fuzzy set “Somewhat tall”, whose graph is given in the following figure.





7. The concept of "being healthy" can be modeled using fuzzy logic. The truth value 0.95 could be assigned to "Fran is healthy" if Fran is almost always healthy. The truth value 0.4 could be assigned to "Leslie is healthy" if Leslie is healthy somewhat less than half the time. The truth of the statements "Fran and Leslie are healthy" would be 0.4 and "Fran is not healthy" would be 0.05.

8. *Behavior closed-loop control systems*: The behavior of some closed-loop control systems can be specified using fuzzy logic. For example, consider an automated heater whose output setting is to be based on the readings of a temperature sensor. A fuzzy set "cold" and the implication "very cold → high" could be used to relate the temperature to the heater settings. The exact behavior of this system is determined by the degree of the constructor used for "very" and by the specific choices of S-norm and complement operators used to define the fuzzy implication—the "engineering parameters" of the system.

1.7.3 PRODUCTION SYSTEMS

Production systems are a logic-based computer programming paradigm introduced by Allen Newell and Herbert Simon in 1975. They are commonly used in intelligent systems for representing an expert's knowledge used in solving some real-world task, such as a physician's knowledge of making medical diagnoses.

Definitions:

A ***fact set*** is a set of ground atomic formulas. These formulas represent the information relevant to the system.

A ***condition*** is a disjunction $A_1 \vee \cdots \vee A_n$, where $n \geq 0$ and each A_i is a literal.

A condition C is ***true*** in a fact set S if:

- C is empty, or
- C is a positive literal and $C \in S$, or
- C is a negative literal $\neg A$, and $B \notin S$ for each ground instance B of A, or
- $C = A_1 \vee \cdots \vee A_n$, and some condition A_i is true in S.

A ***print command*** "print(x)", means that the value of the term x is to be printed.

An ***action*** is either a literal or a print command.

A ***production rule*** is of the form $C_1, \ldots, C_n \rightarrow A_1, \ldots, A_m$, where $n, m \geq 1$, each C_i is a condition, each A_i is an action, and each variable in each action appears in some positive literal in some condition.

The ***antecedent*** of the rule $C_1, \ldots, C_n \rightarrow A_1, \ldots, A_m$ is $C_1, \ldots, C_n$.

The ***consequent*** of the rule $C_1, \ldots, C_n \rightarrow A_1, \ldots, A_m$ is $A_1, \ldots, A_m$.

An ***instantiation*** of a production rule is the rule obtained by replacing each variable in each positive literal in each condition of the rule by a constant.

A ***production system*** consists of a fact set and a set of production rules.

Facts:

1. Given a fact set S, an instantiation $C_1, \ldots, C_n \rightarrow A_1, \ldots, A_m$ of a production rule denotes the following operation:

```
if each condition $C_i$ is true in $S$ then
  for each $A_i$:
    if $A_i$ is an atom, add it to $S$
    if $A_i$ is a negative literal $\neg B$, then remove $B$ from $S$
    if $A_i$ is "print(c)", then print $c$.
```

2. In addition to "print", production systems allow several other system-level commands.

3. OPS5 and CLIPS are currently the most popular languages for writing production systems. They are available for most operating systems, including UNIX and DOS.

4. To initialize a computation prescribed by a production system, the initial fact set and all the production rules are supplied as input. The command "run1" non-deterministically selects an instantiation of a production rule such that all conditions in the antecedent hold in the fact set, and it "fires" the rule by carrying out the actions in the consequent. The command "run" keeps on selecting and firing rules until no more rule instantiations can be selected.

5. Production systems are Turing complete.

Examples:

1. The fact set $S = \{N(3), 3 > 2, 2 > 1\}$ may represent that "3 is a natural number", that "3 is greater than 2", and that "2 is greater than 1".

2. If the fact set S of Example 1 and the production $N(x) \rightarrow \text{print}(x)$ are supplied as input, the command "run" will yield the instantiation $N(3) \rightarrow \text{print}(3)$ and fire it to print 3.

3. The production rule $N(x), x > y \rightarrow \neg N(x), N(y)$ has $N(3), 3 > 2 \rightarrow \neg N(3), N(2)$ as an instantiation. If operated on fact set S of Example 1, this rule will change S to $\{3 > 2, 2 > 1, N(2)\}$.

4. The production system consisting of the following two production rules can be used to add a set of numbers in a fact set:

$$\neg S(x) \rightarrow S(0)$$
$$S(x), N(y) \rightarrow \neg S(x), \neg N(y), S(x+y).$$

For example, starting with the fact set $\{N(1), N(2), N(3), N(4)\}$, this production system will produce the fact set $\{S(10)\}$.

1.7.4 AUTOMATED REASONING

Computers have been used to help prove theorems by verifying special cases. But even more, they have been used to carry out reasoning without external intervention. Developing computer programs that can draw conclusions from a given set of facts is the goal of automated reasoning. There are now automated reasoning programs that can prove results that people have not been able to prove. Automated reasoning can help in verifying the correctness of computer programs, verifying protocol design, verifying hardware design, creating software using logic programming, solving puzzles, and proving new theorems.

Definitions:

Automated reasoning is the process of using a computer program to draw conclusions which follow logically from a set of given facts.

Automated theorem proving is the use of automated reasoning to prove theorems.

A ***proof assistant*** is a computer program that attempts to prove a theorem with the help of user input.

A ***computer-assisted proof*** is a proof that relies on checking the validity of a large number of cases using a special-purpose computer program.

A ***proof done by hand*** is a proof done by a human without the use of a computer.

Facts:

1. Computer-assisted proofs have been used to settle several well-known conjectures, including the Four Color Theorem (§8.6.4), the nonexistence of a finite projective plane of order 10 (§12.2.3), and the densest packing of unit balls in $\mathcal{R}^3$ (§13.2.1).

2. The computer-assisted proofs of both the Four Color Theorem and the nonexistence of a finite projective plane of order 10 rely on having a computer verify certain facts about a large number of cases using special-purpose software.

3. Hardware, system software, and special-purpose program errors can invalidate a computer-assisted proof. This makes the verification of computer-assisted proofs important. However, such verification may be impractical.

4. Automated reasoning software has been developed for both first-order and higher-order logics. A database of automated reasoning systems can be found at

- `http://www-formal.stanford.edu/clt/ARS/systems.html`

5. Automated theorem provers in first-order logic are computer programs that, when given a statement in predicate logic (a conjecture), attempt to find a proof that the statement is always true (and hence, a theorem) or that is sometimes false. Generally, the search for the proof is automatic, that is, without any intervention by a user.

6. Higher-order logic (HOL) extends first-order logic (FOL) by allowing the use of quantifiers over functions and predicates. Computer programs designed to find proofs of statements in HOL are often proof assistants rather than automated theorem provers. These systems rely on user input to help guide their operation.

7. The class of problems an automated theorem prover is designed to solve is known as the *problem domain* of this solver. Some automated theorem provers, such as most FOL provers, have a wide problem domain, but other automated theorem provers are built to solve problems in specific domains or of a specific form.

8. Proofs by mathematical induction pose particular problems for automated proof systems, because of the difficulty in searching how to apply an induction hypotheses, the problem of identifying all cases required for the basis step of a proof, and complications from the use of recursion. Automated proof systems have been built for mathematical induction with varying degrees of success. (See Example 4.)

9. Automated reasoning software has been used to prove new results in many areas, including settling long-standing, well-known open conjectures (such as the Robbins problem described in Example 2).

10. Proofs generated by automated reasoning software can usually be checked without using computers or by using software programs that check the validity of proofs.

11. Proofs done by humans often use techniques ill-suited for implementation in automated proof software.

12. Automated proof systems rely on proof procedures suitable for computer implementation, such as resolution and the semantic tableaux procedure. (See [Fi13] or [Wo96] for details.)

13. The effectiveness of automated proof systems depends on following strategies that help programs prove results efficiently.

14. Restriction strategies are used to block paths of reasoning that are considered to be unpromising.

15. Direction strategies are used to help programs select the approaches to take next.

16. Look-ahead strategies let programs draw conclusions before they would ordinarily be drawn following the basic rules of the program.

17. Redundancy-control strategies are used to eliminate some of the redundancy in retained information.

18. Several efforts have been focused on capturing mathematical knowledge that has been proved by automated reasoning into a database that can be used in automated reasoning systems. (See Examples 6-7.)

19. Automated theorem proving and automated reasoning are useful for verifying that computer programs are correct and that hardware incorporates the functions for which it is intended. Automated theorem proving can also be used to establish that network protocols are secure.

20. To learn more about automated reasoning and automated theorem proving, consult [Fi13] and [RoVo01].

Examples:

1. The OTTER system (now known as Prover9) is an automated reasoning system based on resolution for first-order logic that was developed at Argonne National Laboratory [Wo96]. It was used to establish many previously unknown results in a wide variety of areas, including algebraic curves, lattices, Boolean algebra, groups, semigroups, and logic. A summary of these results can be found at

- http://www.cs.unm.edu/~mccune/prover9

2. The automated reasoning system EQP, developed at Argonne National Laboratory, settled the Robbins problem in 1996. This problem was first proposed in the 1930s by Herbert Robbins and was actively worked on by many mathematicians. The Robbins problem can be stated as follows. Can the equivalence

$$\neg(\neg p) \Leftrightarrow p$$

be derived from the commutative and associative laws for the "or" operator $\vee$ and the identity

$$\neg(\neg(p \vee q) \vee \neg(p \vee \neg q)) \Leftrightarrow p?$$

The EQP system, using some earlier work that established a sufficient condition for the truth of Robbins' problem, found a 15-step proof of the theorem after approximately 8 days of searching on a UNIX workstation when provided with one of several different search strategies.

3. Isabelle is an interactive theorem prover developed at the University of Cambridge and Technische Universität München. Isabelle can be used to encode first-order logic, higher-order logic, Zermelo-Fraenkel set theory, and other logics. Isabelle's main proof method is a higher-order version of resolution. Isabelle is interactive and also features efficient automatic reasoning tools. It comes with a large library of formally verified proofs from number theory, analysis, algebra, and set theory. It can be accessed at

- https://isabelle.in.tum.de/index.html

4. The Boyer-Mayer theorem prover (NQTHM) has had some notable successes with automating the proofs of theorems using mathematical induction. (See [BoMo79].)

5. The WZ computer-assisted and automated theorem prover, developed by H. Wilf and D. Zeilberger, has become a valuable tool for proving combinatorial identities. (See Section 3.7 for details.)

6. The goal of the QED Project, active from 1993 until 1996 was to build a repository that represents all important, established mathematical knowledge. It was hoped that it could help mathematicians cope with the explosion of mathematical knowledge and help in developing and verifying computer systems.

7. The Mizar system, founded by A. Trybulec, has a formal language for writing mathematical definitions and proofs, a proof assistant for mechanically checking proofs in this language, and a library of formalized theorems, called the Mizar Mathematical Library (MML), that can be used to help prove new results. In 2014 the MML included more than 10,000 formalized definitions and more than 50,000 theorems. This library is available at

- http://mizar.uwb.edu.pl/library

COUNTING METHODS

INTRODUCTION

Many problems in mathematics, computer science, and engineering involve counting objects with particular properties. Although there are no absolute rules that can be used to solve all counting problems, many counting problems that occur frequently can be solved using a few basic rules together with a few important counting techniques. This chapter provides information on how many standard counting problems are solved.

GLOSSARY

binomial coefficient: the coefficient $\binom{n}{k}$ of $x^k y^{n-k}$ in the expansion of $(x+y)^n$.

coloring pattern (with respect to a set of symmetries of a figure): a set of mutually equivalent colorings.

combination (from a set S): a subset of S; any unordered selection from S. A ***k-combination*** from a set is a subset of k elements of the set.

combination coefficient: the number $C(n,k)$ (equal to $\binom{n}{k}$) of ways to make an unordered choice of k items from a set of n items.

combination-with-replacement (from a set S): any unordered selection with replacement; a multiset of objects from S.

combination-with-replacement coefficient: the number of ways to choose a multiset of k items from a set of n items, written $C^R(n,k)$.

composition: a partition in which the order of the parts is taken into account.

cycle index: for a permutation group G, the multivariate polynomial P_G obtained by dividing the sum of the cycle structure representations of all the permutations in G by the number of elements of G.

cycle structure (of a permutation): a multivariate monomial whose exponents record the number of cycles of each size.

derangement: a permutation on a set that leaves no element fixed.

exponential generating function (for $\{a_k\}_0^\infty$): the formal sum $\sum_{k=0}^{\infty} a_k \frac{x^k}{k!}$, or any equivalent closed-form expression.

falling power: the product $x^{\underline{k}} = x(x-1)\dots(x-k+1)$ of k consecutive factors starting with x, each factor decreasing by 1.

Ferrers diagram: a geometric, left-justified, and top-justified array of cells, boxes, dots or nodes representing a partition of an integer, in which each row of dots corresponds to a part of the partition.

Gaussian binomial coefficient: the algebraic expression $\begin{bmatrix} n \\ k \end{bmatrix}$ in the variable q defined for nonnegative integers n and k by $\begin{bmatrix} n \\ k \end{bmatrix} = \frac{q^n-1}{q-1} \cdot \frac{q^{n-1}-1}{q^2-1} \cdots \frac{q^{n+1-k}-1}{q^k-1}$ for $0 < k \leq n$ and $\begin{bmatrix} n \\ 0 \end{bmatrix} = 1$.

generating function (or ***ordinary generating function***) for $\{a_k\}_0^\infty$: the formal sum $\sum_{k=0}^{\infty} a_k x^k$, or any equivalent closed-form expression.

hook (of a cell in a Ferrers diagram): the set of cells directly to the right or directly below a given cell, together with the cell itself.

hooklength (of a cell in a Ferrers diagram): the number of cells in the hook of that cell.

Kronecker delta function: the function $\delta(x, y)$ defined by the rule $\delta(x, y) = 1$ if $x = y$ and 0 otherwise.

lexicographic order: the order in which a list of strings would appear in a dictionary.

Möbius function: the function $\mu(m)$ where

$$\mu(m) = \begin{cases} 1 & \text{if } m = 1 \\ (-1)^k & \text{if } m \text{ is a product of } k \text{ distinct primes} \\ 0 & \text{if } m \text{ is divisible by the square of a prime,} \end{cases}$$

or a generalization of this function to partially ordered sets.

multinomial coefficient: the coefficient $\binom{n}{k_1\ k_2\ \ldots\ k_m}$ of $x_1^{k_1} x_2^{k_2} \ldots x_m^{k_m}$ in the expansion of $(x_1 + x_2 + \cdots + x_m)^n$.

ordered selection (of k items from a set S): a nonrepeating list of k items from S.

ordered selection with replacement (of k items from a set S): a possibly-repeating list of k items from S.

ordinary generating function (for the sequence $\{a_k\}_0^\infty$): See *generating function*.

overpartition: a partition in which at most one occurrence of each integer appearing as a part is distinguished as being overlined.

partially ordered set (or ***poset***): a set S together with a binary relation $\leq$ that is reflexive, antisymmetric, and transitive, written $(S, \leq)$.

partition: an unordered decomposition of an integer into a sum of positive integers.

Pascal's triangle: a triangular table with the binomial coefficient $\binom{n}{k}$ appearing in row n, column k.

pattern inventory: a generating function that enumerates the number of coloring patterns.

permutation: a one-to-one mapping of a set of elements onto itself, or an arrangement of the set into a list. A ***k-permutation*** of a set is an ordered nonrepeating sequence of k elements of the set.

permutation coefficient: the number of ways to choose a nonrepeating list of k items from a set of n items, written $P(n, k)$.

permutation group: a nonempty set P of permutations on a set S, such that P is closed under composition and under inversion.

permutation-with-replacement coefficient: the number of ways to choose a possibly repeating list of k items from a set of n items, written $P^R(n, k)$.

poset: See *partially ordered set*.

problème des ménages: the problem of finding the number of ways that married couples can be seated around a circular table so that no men are adjacent, no women are adjacent, and no husband and wife are adjacent.

problème des rencontres: given balls 1 through n drawn out of an urn one at a time, the problem of finding the probability that ball i is never the ith one drawn.

Stirling cycle number: the number $\left[{n \atop k}\right]$ of ways to partition n objects into k nonempty cycles.

Stirling number of the first kind: the coefficient $s(n,k)$ of x^k in the polynomial $x(x-1)(x-2)\dots(x-n+1)$.

Stirling number of the second kind: the coefficient $S(n,k)$ of $x^{\underline{k}}$ in the representation $x^n = \sum_k S(n,k)x^{\underline{k}}$ of x^n as a linear combination of falling powers.

Stirling subset number: the number $\left\{ {n \atop k} \right\}$ of ways to partition n objects into k nonempty subsets.

symmetry (of a figure): a spatial motion that maps the figure onto itself.

tree diagram: a tree that displays the different alternatives in some counting process.

unordered selection (of k items from a set S): a subset of k items from S.

unordered selection (of k items from a set S with replacement): a selection of k objects in which each object in the selection set S can be chosen arbitrarily often and such that the order in which the objects are selected does not matter.

Young tableau: an array obtained by replacing each cell of a Ferrers diagram by a positive integer.

2.1 SUMMARY OF COUNTING PROBLEMS

Table 1 lists many important counting problems, gives the number of objects being counted, together with a reference to the section of this *Handbook* where details can be found. Table 2 lists several important counting rules and methods, and gives the types of counting problems that can be solved using these rules and methods. Notation used in this table is given at the end of the table.

Table 1: Counting problems.

objects	*number of objects*	*reference*
Arranging objects in a row:		
n distinct objects	$n! = P(n,n) = n(n-1)\dots 2\cdot 1$	§2.3.1
k out of n distinct objects	$n^{\underline{k}} = P(n,k) = n(n-1)\dots(n-k+1)$	§2.3.1
some of the n objects are identical: k_1 of a first kind, k_2 of a second kind, …, k_j of a jth kind, and where $k_1+k_2+\dots+k_j=n$	$\binom{n}{k_1\,k_2\,\dots\,k_j} = \frac{n!}{k_1!\,k_2!\dots k_j!}$	§2.3.2
none of the n objects remains in its original place (derangements)	$D_n = n!\left(1-\frac{1}{1!}+\dots+(-1)^n\frac{1}{n!}\right)$	§2.4.2
Arranging objects in a circle (where rotations, but not reflections, are equivalent):		
n distinct objects	$(n-1)!$	§2.2.1
k out of n distinct objects	$\frac{P(n,k)}{k}$	§2.2.1
Choosing k objects from n distinct objects:		
order matters, no repetitions	$P(n,k) = \frac{n!}{(n-k)!} = n^{\underline{k}}$	§2.3.1

objects	*number of objects*	*reference*
order matters, repetitions allowed	$P^R(n,k) = n^k$	§2.3.3
order does not matter, no repetitions	$C(n,k) = \binom{n}{k} = \frac{n!}{k!(n-k)!}$	§2.3.2
order does not matter, repetitions allowed	$C^R(n,k) = \binom{n+k-1}{k}$	§2.3.3
Subsets:		
of size k from a set of size n	$\binom{n}{k}$	§2.3.2
of all sizes from a set of size n	2^n	§2.3.4
of $\{1,\ldots,n\}$, without consecutive elements	F_{n+2}	§3.1.2
Placing n objects into k cells:		
distinct objects, distinct cells	k^n	§2.2.1
distinct objects, distinct cells, no cell empty	$\left\{ {n \atop k} \right\} k!$	§2.5.2
distinct objects, identical cells	$\left\{ {n \atop 1} \right\} + \left\{ {n \atop 2} \right\} + \cdots + \left\{ {n \atop k} \right\} = B_n$	§2.5.2
distinct objects, identical cells, no cell empty	$\left\{ {n \atop k} \right\}$	§2.5.2
distinct objects, distinct cells, with k_i in cell i ($i = 1,\ldots,n$), where $k_1 + k_2 + \cdots + k_j = n$	$\binom{n}{k_1\, k_2 \ldots k_j}$	§2.3.2
identical objects, distinct cells	$\binom{n+k-1}{n}$	§2.3.3
identical objects, distinct cells, no cell empty	$\binom{n-1}{k-1}$	§2.3.3
identical objects, identical cells	$p_k(n)$	§2.5.1
identical objects, identical cells, no cell empty	$p_k(n) - p_{k-1}(n)$	§2.5.1
Placing n distinct objects into k nonempty cycles	$\left[{n \atop k} \right]$	§2.5.2
Solutions to $x_1 + \cdots + x_n = k$:		
nonnegative integers	$\binom{k+n-1}{k} = \binom{k+n-1}{n-1}$	§2.3.3
positive integers	$\binom{k-1}{n-1}$	§2.3.3
integers where $0 \le a_i \le x_i$ for all i	$\binom{k-(a_1+\cdots+a_n)+n-1}{n-1}$	§2.3.3
integers where $0 \le x_i \le a_i$ for one or more i	inclusion/exclusion principle	§2.4.2
integers with $x_1 \ge \cdots \ge x_n \ge 1$	$p_n(k) - p_{n-1}(k)$	§2.5.1
integers with $x_1 \ge \cdots \ge x_n \ge 0$	$p_n(k)$	§2.5.1
Solutions to $x_1 + x_2 + \cdots + x_n = n$ in nonnegative integers where $x_1 \ge x_2 \ge \cdots \ge x_n \ge 0$	$p(n)$	§2.5.1
Solutions to $x_1 + 2x_2 + 3x_3 + \cdots + nx_n = n$ in nonnegative integers	$p(n)$	§2.5.1

objects	*number of objects*	*reference*
Functions from a k-element set to an n-element set:		
all functions	n^k	§2.2.1
one-to-one functions ($n \geq k$)	$n^{\underline{k}} = \frac{n!}{(n-k)!} = P(n,k)$	§2.2.1
onto functions ($n \leq k$)	inclusion/exclusion	§2.4.2
partial functions	$\binom{k}{0}+\binom{k}{1}n+\cdots+\binom{k}{k}n^k = (n+1)^k$	§2.3.2
Bit strings of length n:		
all strings	2^n	§2.2.1
with given entries in k positions	2^{n-k}	§2.2.1
with exactly k 0s	$\binom{n}{k}$	§2.3.2
with at least k 0s	$\binom{n}{k}+\binom{n}{k+1}+\cdots+\binom{n}{n}$	§2.3.2
with equal numbers of 0s and 1s	$\binom{n}{n/2}$	§2.3.2
Palindromes	$2^{\lceil n/2 \rceil}$	§2.2.1
with an even number of 0s	2^{n-1}	§2.3.4
without consecutive 0s	F_{n+2}	§3.1.2
Partitions of a positive integer n into positive summands:		§2.5.1
total number	$p(n)$	
into at most k parts	$p_k(n)$	
into exactly k parts	$p_k(n) - p_{k-1}(n)$	
into parts each of size $\leq k$	$p_k(n)$	
Partitions of a set of size n:		
all partitions	$B(n)$	§2.5.2
into k parts	$\left\{ {n \atop k} \right\}$	§2.5.2
into k parts, each part having at least two elements	$b(n,k)$	§3.1.8
Paths:		
from $(0,0)$ to $(2n,0)$ made up of line segments from (i,y_i) to $(i+1,y_{i+1})$; integer $y_i \geq 0$, $y_{i+1} = y_i \pm 1$	C_n	§3.1.3
from $(0,0)$ to $(2n,0)$ made up of line segments from (i,y_i) to $(i+1,y_{i+1})$; integer $y_i > 0$ (for $0 < i < 2n$), $y_{i+1} = y_i \pm 1$	C_{n-1}	§3.1.3
from $(0,0)$ to (m,n) that move 1 unit up or right at each step	$\binom{m+n}{n}$	§2.3.2
Permutations of $\{1,\ldots,n\}$:		
all permutations	$n!$	§2.3.1
with k cycles, all cycles of length ≥ 2	$d(n,k)$	§3.1.8
with k descents	$E(n,k)$	§3.1.5
with k excedances	$E(n,k)$	§3.1.5
alternating, n even	$(-1)^{n/2}E_n$	§3.1.7

objects	*number of objects*	*reference*
alternating, n odd	T_n	§3.1.7
Symmetries of regular figures:		§2.6
n-gon	$2n$	
tetrahedron	12	
cube	24	
octahedron	24	
dodecahedron	60	
icosahedron	60	
Coloring regular 2-dimensional & 3-dimensional figures with $\leq k$ colors:		§2.6
corners of an n-gon, allowing rotations and reflections	$\frac{1}{2n}\sum_{d\mid n}\varphi(d)k^{\frac{n}{d}} + \frac{1}{2}k^{\frac{(n+1)}{2}}$, n odd $\frac{1}{2n}\sum_{d\mid n}\varphi(d)k^{\frac{n}{d}}+\frac{1}{4}(k^{\frac{n}{2}} + k^{\frac{(n+2)}{2}})$, n even	
corners of an n-gon, allowing only rotations	$\frac{1}{n}\sum_{d\mid n}\varphi(d)k^{\frac{n}{d}}$	
corners of a triangle, allowing rotations and reflections	$\frac{1}{6}[k^3 + 3k^2 + 2k]$	
corners of a triangle, allowing only rotations	$\frac{1}{3}[k^3 + 2k]$	
corners of a square, allowing rotations and reflections	$\frac{1}{8}[k^4 + 2k^3 + 3k^2 + 2k]$	
corners of a square, allowing only rotations	$\frac{1}{4}[k^4 + k^2 + 2k]$	
corners of a pentagon, allowing rotations and reflections	$\frac{1}{10}[k^5 + 5k^3 + 4k]$	
corners of a pentagon, allowing only rotations	$\frac{1}{5}[k^5 + 4k]$	
corners of a hexagon, allowing rotations and reflections	$\frac{1}{12}[k^6 + 3k^4 + 4k^3 + 2k^2 + 2k]$	
corners of a hexagon, allowing only rotations	$\frac{1}{6}[k^6 + k^3 + 2k^2 + 2k]$	
corners of a tetrahedron	$\frac{1}{12}[k^4 + 11k^2]$	
edges of a tetrahedron	$\frac{1}{12}[k^6 + 3k^4 + 8k^2]$	
faces of a tetrahedron	$\frac{1}{12}[k^4 + 11k^2]$	
corners of a cube	$\frac{1}{24}[k^8 + 17k^4 + 6k^2]$	
edges of a cube	$\frac{1}{24}[k^{12} + 6k^7 + 3k^6 + 8k^4 + 6k^3]$	
faces of a cube	$\frac{1}{24}[k^6 + 3k^4 + 12k^3 + 8k^2]$	
Number of sequences of wins/ losses in $\frac{n+1}{2}$-out-of-n playoff series (n odd)	$2C(n, \frac{n+1}{2})$	§2.3.2
Sequences $a_1, \ldots, a_{2n}$ having n 1s and n -1s; each partial sum $a_1 + \cdots + a_k \geq 0$	C_n	§3.1.3

objects	*number of objects*	*reference*
Well-formed sequences of parentheses of length $2n$	C_n	§3.1.3
Well-parenthesized products of $n+1$ variables	C_n	§3.1.3
Triangulations of a convex $(n+2)$-gon	C_n	§3.1.3

Notation:

$B(n)$ or B_n: Bell number

$b(n,k)$: associated Stirling number of the second kind

$C_n = \frac{1}{n+1}\binom{2n}{n}$: Catalan number

$C(n,k) = \binom{n}{k} = \frac{n!}{k!(n-k)!}$: binomial coefficient

$d(n,k)$: associated Stirling number of the first kind

E_n: Euler number

φ: Euler phi-function

$E(n,k)$: Eulerian number

F_n: Fibonacci number

$n^{\underline{k}} = n(n-1)\dots(n-k+1) = P(n,k)$: falling power

$P(n,k) = \frac{n!}{(n-k)!}$: k-permutation

$p(n)$: number of partitions of n

$p_k(n)$: number of partitions of n into at most k summands

$p_k^*(n)$: number of partitions of n into exactly k summands

$\left[{n \atop k}\right]$: Stirling cycle number

$\left\{{n \atop k}\right\}$: Stirling subset number

T_n: tangent number

Table 2: Methods of counting and the problems they solve.

statement	*technique of proof*
rule of sum (§2.2.1)	problems that can be broken into disjoint cases, each of which can be handled separately
rule of product (§2.2.1)	problems that can be broken into sequences of independent counting problems, each of which can be solved separately
rule of quotient (§2.2.1)	problems of counting arrangements, where the arrangements can be divided into collections that are all of the same size
pigeonhole principle (§2.2.3)	problems with two sets of objects, where one set of objects needs to be matched with the other
inclusion/exclusion principle (§2.4)	problems that involve finding the size of a union of sets, where some or all the sets in the union may have common elements
permutations (§2.2.1, §2.3.1, §2.3.3)	problems that require counting the number of selections or arrangements, where order within the selection or arrangement matters
combinations (§2.3.2, §2.3.3)	problems that require counting the number of selections or sets of choices, where order within the selection does not matter

statement	*technique of proof*
recurrence relations (§2.2.4)	problems that require an answer depending on the integer n, where the solution to the problem for a given size n can be related to one or more cases of the problem for smaller sizes
generating functions (§2.2.5)	problems that can be solved by finding a closed form for a function that represents the problem and then manipulating the closed form to find a formula for the coefficients
Pólya counting (§2.6.5)	problems that require a listing or number of patterns, where the patterns are not to be regarded as different under certain types of motions (such as rotations and reflections)
Möbius inversion (§2.7.1)	problems that involve counting certain types of circular permutations

2.2 BASIC COUNTING TECHNIQUES

Most counting methods are based directly or indirectly on the fundamental principles and techniques presented in this section. The rules of sum, product, and quotient are the most basic and are applied more often than any other. The section also includes some applications of the pigeonhole principle, a brief introduction to generating functions, and several examples illustrating the use of tree diagrams and Venn diagrams.

2.2.1 RULES OF SUM, PRODUCT, AND QUOTIENT

Definitions:

The ***rule of sum*** states that when there are m cases such that the ith case has n_i options, for $i = 1, \ldots, m$, and no two of the cases have any options in common, the total number of options is $n_1 + n_2 + \cdots + n_m$.

The ***rule of product*** states that when a procedure can be broken down into m steps, such that there are n_1 options for Step 1, and such that after the completion of Step $i-1$ $(i = 2, \ldots, m)$ there are n_i options for Step i, the number of ways of performing the procedure is $n_1 n_2 \ldots n_m$.

The ***rule of quotient*** states that when a set S is partitioned into equal-sized subsets of m elements each, there are $\frac{|S|}{m}$ subsets.

An ***m-permutation*** of a set S with n elements is a nonrepeating ordered selection of m elements of S, that is, a sequence of m distinct elements of S. An n-permutation is simply called a ***permutation*** of S.

Facts:

1. The rule of sum can be stated in set-theoretic terms: if sets $S_1, \ldots, S_m$ are finite and pairwise disjoint, then $|S_1 \cup S_2 \cup \cdots \cup S_m| = |S_i| + |S_2| + \cdots + |S_m|$.

2. The rule of product can be stated in set-theoretic terms: if sets $S_1, \ldots, S_m$ are finite, then $|S_1 \times S_2 \times \cdots \times S_m| = |S_1| \cdot |S_2| \cdot \cdots \cdot |S_m|$.

3. The rule of quotient can be stated in terms of the equivalence classes of an equivalence relation on a finite set S: if every class has m elements, then there are $|S|/m$ equivalence classes.

4. Venn diagrams (§1.2.2) are often used as an aid in counting the elements of a subset, as an auxiliary to the rule of sum. This generalizes to the principle of inclusion/exclusion (§2.4).

5. Counting problems can often be solved by using a combination of counting methods, such as the rule of sum and the rule of product.

Examples:

1. *Counting bit strings*: There are 2^n bit strings of length n, since such a bit string consists of n bits, each of which is either 0 or 1.

2. *Counting bit strings with restrictions*: There are 2^{n-2} bit strings of length n ($n \geq 2$) that begin with two 1s, since forming such a bit string consists of filling in $n-2$ positions with 0s or 1s.

3. *Counting palindromes*: A palindrome is a string of symbols that is unchanged if the symbols are written in reverse order, such as *rpnbnpr* or 10011001. There are $k^{\lceil n/2 \rceil}$ palindromes of length n where the symbols are chosen from a set of k symbols.

4. *Counting the number of variable names*: Determine the number of variable names, subject to the following rules: a variable name has four or fewer characters, the first character is a letter, the second and third are letters or digits, and the fourth must be X or Y or Z. Partition the names into four sets, S_1, S_2, S_3, S_4, containing names of length 1, 2, 3, and 4 respectively. Then $|S_1| = 26$, $|S_2| = 26 \times 36$, $|S_3| = 26 \times 36^2$, and $|S_4| = 26 \times 36^2 \times 3$. Therefore the total number of names equals $|S_1|+|S_2|+|S_3|+|S_4| = 135{,}746$.

5. *Counting functions*: There are n^m functions from a set $A = \{a_1, \ldots, a_m\}$ to a set $B = \{b_1, \ldots, b_n\}$. (Construct each function $f : A \to B$ by an m-step process, where Step i involves selecting the value $f(a_i)$.)

6. *Counting one-to-one functions*: There are $n(n-1)\ldots(n-m+1)$ one-to-one functions from $A = \{a_1, \ldots, a_m\}$ to $B = \{b_1, \ldots, b_n\}$. If values $f(a_1), \ldots, f(a_{i-1})$ have already been selected in set B during the first $i-1$ steps, then there are $n-i+1$ possible values remaining for $f(a_i)$.

7. *Counting permutations*: There are $n(n-1)\ldots(n-m+1) = \frac{n!}{(n-m)!}$ m-permutations of an n-element set. (Each one-to-one function in Example 6 may be viewed as an m-permutation of B.) (Permutations are discussed in §2.3.)

8. *Counting circular permutations*: There are $(n-1)!$ ways to seat n people around a round table (where rotations are regarded as equivalent, but the clockwise/counterclockwise distinction is maintained). The total number of arrangements is $n!$ and each equivalence class contains n configurations. By the rule of quotient, the number of arrangements is $\frac{n!}{n} = (n-1)!$.

9. *Counting restricted circular permutations*: If n women and n men are to be seated around a circular table, with no two of the same sex seated next to each other, the number of possible arrangements is $n(n-1)!^2$.

2.2.2 TREE DIAGRAMS

When a counting problem can be decomposed into cases, a tree can be used to make sure that every case is counted, and that no case is counted twice.

Definitions:

A ***tree diagram*** is a line-drawing of a tree, often with its branches and/or nodes labeled. The ***root*** represents the start of a procedure and the ***branches*** at each node represent the options for the next step.

Facts:

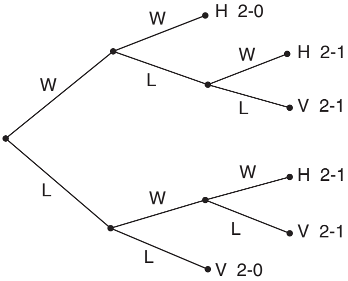
1. Tree diagrams can be used as an important auxiliary to the rules of sum and product.

2. The objective in a tree-counting approach is often one of the following:

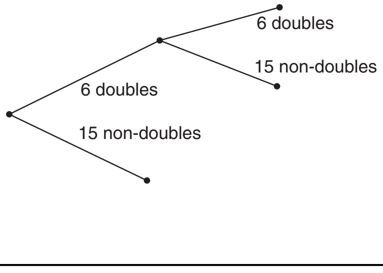
- the number of leaves (endnodes);
- the number of nodes;
- the sum of the path products.

Examples:

1. There are six possible sequences of wins and losses when the home team (H) plays the visiting team (V) in a best 2-out-of-3 playoff. In the following tree diagram each edge label indicates whether the home team won or lost the corresponding game, and the label at each final node is the outcome of the playoff. The number of different possible sequences equals the number of endnodes, namely 6.



2. Suppose that an experimental process begins by tossing two identical dice. If the dice match, the process continues for a second round; if not, the process stops at one round. Thus, an experimental outcome sequence consists of one or two unordered pairs of numbers from 1 to 6. The three paths in the following tree represent the three different kinds of outcome sequences. The total number of possible outcomes is the sum of the path products $6^2 + 6 \cdot 15 + 15 = 141$.



2.2.3 PIGEONHOLE PRINCIPLE

Definitions:

The ***pigeonhole principle*** (***Dirichlet drawer principle***) states that if $n + 1$ objects (pigeons) are placed into n boxes (pigeonholes), then some box contains more than one object. (Peter Gustav Lejeune Dirichlet, 1805–1859)

The ***generalized pigeonhole principle*** states that if m objects are placed into k boxes, then some box contains at least $\lceil \frac{m}{k} \rceil$ objects.

The ***set-theoretic form of the pigeonhole principle*** states that if $f\colon S \to T$, where S and T are finite and any two of the following conditions hold, then so does the third:

- f is one-to-one;
- f is onto;
- $|S| = |T|$.

Examples:

1. Among any group of eight people, at least two were born on the same day of the week. This follows since there are seven pigeonholes (the seven days of the week) and more than seven pigeons (the eight people).

2. Among any group of 25 people, at least four were born on the same day of the week. This follows from the generalized pigeonhole principle with $m = 25$ and $k = 7$, yielding $\lceil \frac{m}{k} \rceil = \lceil \frac{25}{7} \rceil = 4$.

3. Suppose that a dresser drawer contains many black socks and blue socks. If choosing in total darkness, a person must grab at least three socks to be absolutely certain of having a pair of the same color. The two colors are pigeonholes; the pigeonhole principle says that three socks (the pigeons) are enough.

4. What is the minimum number of points whose placement in the interior of a 2×2 square guarantees that at least two of them are less than $\sqrt{2}$ units apart? Four points are not enough, since they could be placed near the respective corners of the 2×2 square. To see that five is enough, partition the 2×2 square into four 1×1 squares. By the pigeonhole principle, one of these 1×1 squares must contain at least two of the points, and these two must be less than $\sqrt{2}$ units apart.

5. In any set of $n+1$ positive integers, each less than or equal to $2n$, there are at least two such that one is a multiple of the other. To see this, express each of the $n+1$ numbers in the form $2^k \cdot q$, where q is odd. Since there are only n possible odd values for q between 1 and $2n$, at least two of the $n+1$ numbers must have the same q, and the result follows.

6. Let B_1 and B_2 be any two bit strings, each consisting of five ones and five zeros. Then there is a cyclic shift of bit string B_2 so that the resulting string B_2' matches B_1 in at least five of its positions. For example, if $B_1 = 1010101010$ and $B_2 = 0001110101$, then $B_2' = 1000111010$ satisfies the condition. Observe that there are 10 possible cyclic shifts of bit string B_2. For $i = 1, \ldots, 10$, the ith bit of exactly five of these strings will match the ith bit of B_1. Thus, there is a total of 50 bitmatches over the set of 10 cyclic shifts. The generalized pigeonhole principle implies that there is at least one cyclic shift having $\lceil \frac{50}{10} \rceil = 5$ matching bits.

7. Every sequence of n^2+1 distinct real numbers must have an increasing or decreasing subsequence of length $n+1$. Given a sequence $a_1, \ldots, a_{n^2+1}$, for each a_j let d_j and i_j be the lengths of the longest decreasing and increasing subsequences beginning with a_j. This gives a sequence of n^2+1 ordered pairs (d_j, i_j). If there were no increasing or decreasing subsequence of length $n+1$, then there are only n^2 possible ordered pairs (d_j, i_j), since $1 \le d_j \le n$ and $1 \le i_j \le n$. By the pigeonhole principle, at least two ordered pairs must be identical. Hence there are p and q such that $d_p = d_q$ and $i_p = i_q$. If $a_p < a_q$, then the sequence a_p followed by the increasing subsequence starting at a_q gives an increasing subsequence of length greater than i_q, a contradiction. A similar contradiction to the choice of d_p follows if $a_q < a_p$. Hence a decreasing or increasing subsequence of length $n+1$ must exist.

2.2.4 SOLVING COUNTING PROBLEMS USING RECURRENCE RELATIONS

Certain types of counting problems can be solved by modeling the problem using a recurrence relation (§3.3) and then working with the recurrence relation.

Facts:

1. The following general procedure is used for solving a counting problem using a recurrence relation:

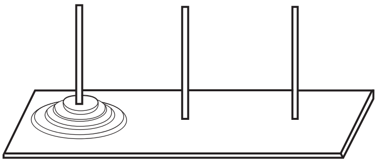
- Let a_n be the solution of the counting problem for the parameter n;
- Determine a recurrence relation for a_n, together with the appropriate number of initial conditions;
- Find the particular value of the sequence that solves the original counting problem by repeated use of the recurrence relation or by finding an explicit formula for a_n and evaluating it at n.

2. There are many techniques for solving recurrence relations which may be useful in the solution of counting problems. Section 3.3 provides general material on recurrence relations and contains many examples illustrating how counting problems are solved using recurrence relations.

Examples:

1. *Tower of Hanoi*: The Tower of Hanoi puzzle consists of three pegs mounted on a board and n disks of different sizes. Initially the disks are on the first peg in order of decreasing size. See the following figure, using four disks. The rules allow disks to be moved one at a time from one peg to another, with no disk ever placed atop a smaller one. The goal of the puzzle is to move the tower of disks to the second peg, with the largest on the bottom. How many moves are needed to solve this puzzle for 64 disks?

Let a_n be the minimum number of moves to solve the Tower of Hanoi puzzle with n disks. Transferring the $n-1$ smallest disks from peg 1 to peg 3 requires a_{n-1} moves. One move is required to transfer the largest disk to peg 2, and transferring the $n-1$ disks now on peg 3 to peg 2, placing them atop the largest disk, requires a_{n-1} moves. Hence the puzzle with n disks can be solved using $2a_{n-1}+1$ moves. The puzzle for n disks cannot be solved in fewer steps, since then the puzzle with $n-1$ disks could be solved using fewer than a_{n-1} moves. Hence $a_n = 2a_{n-1}+1$. The initial condition is $a_1 = 1$. Iterating shows that $a_n = 2a_{n-1}+1 = 2^2a_{n-2}+2+1 = \cdots = 2^{n-1}a_1 + 2^{n-2} + \cdots + 2^2 + 2 + 1 = 2^n - 1$. So $2^{64}-1$ moves are required to solve this problem for 64 disks. (Example 3 of §3.3.3 and Example 1 of §3.3.4 provide alternative methods for solving this recurrence relation.)



2. *Reve's puzzle*: The Reve's puzzle is the variation of the Tower of Hanoi puzzle that follows the same rules as the Tower of Hanoi puzzle, but uses four pegs.

The minimum number of moves needed to solve the Reve's puzzle for n disks is not known, but it is conjectured that this number is $R(n) = \sum_{i=1}^{k} i2^{i-1} - \left(\frac{k(k+1)}{2} - n\right)2^{k-1}$ where k is the smallest integer such that $n \leq \frac{k(k+1)}{2}$.

The following recursive approach, the *Frame-Stewart algorithm*, gives a method for solving the Reve's puzzle by moving n disks from peg 1 to peg 4 in $R(n)$ moves. If $n = 1$, move the single disk from peg 1 to peg 4. If $n > 1$: recursively move the $n - k$ smallest disks from peg 1 to peg 2 using the Frame-Stewart algorithm; then move the k largest disks from peg 1 to peg 4 using the 3-peg algorithm from Example 1 on pegs 1, 3, and 4; and finally recursively move the $n - k$ smallest disks from peg 2 to peg 4 using the Frame-Stewart algorithm.

3. How many strings of four decimal digits contain an even number of 0s? Let a_n be the number of strings of n decimal digits that contain an even number of 0s. To obtain such a string: (1) append a nonzero digit to a string of $n-1$ decimal digits that has an even number of 0s, which can be done in $9a_{n-1}$ ways; or (2) append a 0 to a string of $n-1$ decimal digits that has an odd number of 0s, which can be done in $10^{n-1} - a_{n-1}$ ways. Hence $a_n = 9a_{n-1} + (10^{n-1} - a_{n-1}) = 8a_{n-1} + 10^{n-1}$. The initial condition is $a_1 = 9$. It follows that $a_2 = 8a_1 + 10 = 82$, $a_3 = 8a_2 + 100 = 756$, and $a_4 = 8a_3 + 1{,}000 = 7{,}048$.

2.2.5 SOLVING COUNTING PROBLEMS USING GENERATING FUNCTIONS

Some counting problems can be solved by finding a closed form for the function that represents the problem and then manipulating the closed form to find the relevant coefficient.

Facts:

1. Use the following procedure for solving a counting problem by using a generating function:

- Let a_n be the solution of the counting problem for the parameter n;
- Find a closed form for the generating function $f(x)$ that has a_n as the coefficient of x^n in its power series;
- Solve the counting problem by computing a_n by expanding the closed form and examining the coefficient of x^n.

2. Generating functions can be used to solve counting problems that reduce to finding the number of solutions to an equation of the form $x_1 + x_2 + \cdots + x_n = k$, where k is a positive integer and the x_is are integers subject to constraints.

3. There are many techniques for manipulating generating functions (§3.2, §3.3.4) which may be useful in the solution of counting problems. Section 3.2 contains examples of counting problems solved using generating functions.

Examples:

1. How many ways are there to distribute eight identical cookies to three children if each child receives at least two and no more than four cookies. Let c_n be the number of ways to distribute n identical cookies in this way. Then c_n is the coefficient of x^n in $(x^2 + x^3 + x^4)^3$, since a distribution of n cookies to the three children is equivalent to a solution of $x_1 + x_2 + x_3 = 8$ with $2 \le x_i \le 4$ for $i = 1, 2, 3$. Expanding this product shows that c_8, the coefficient of x_8, is 6. Hence there are six ways to distribute the cookies.

2. An urn contains colored balls, where each ball is either red, blue, or black, there are at least ten balls of each color, and balls of the same color are indistinguishable. Find the number of ways to select ten balls from the urn so that an odd number of red balls, an even number of blue balls, and at least five black balls are selected. If x_1, x_2, and x_3 denote the number of red balls, blue balls, and black balls selected, respectively, the answer is provided by the number of nonnegative integer solutions of $x_1 + x_2 + x_3 = 10$ with x_1 odd, x_2 even, $x_3 \geq 5$. This is the coefficient of x^{10} in the generating function $f(x) = (x+x^3+x^5+x^7+x^9+\cdots)(1+x^2+x^4+x^6+x^8+x^{10}+\cdots)(x^5+x^6+x^7+x^8+x^9+x^{10}+\cdots)$. Since the coefficient of x^{10} in the expansion is 6, there are six ways to select the balls as specified.

2.3 PERMUTATIONS AND COMBINATIONS

Permutations count the number of arrangements of objects, and combinations count the number of ways to select objects from a set. A permutation coefficient counts the number of ways to arrange a set of objects, whereas a combination coefficient counts the number of ways to select a subset.

2.3.1 ORDERED SELECTION: FALLING POWERS

Falling powers mathematically model the process of selecting k items from a collection of n items in circumstances where the ordering of the selection matters and repetition is not allowed.

Definitions:

An ***ordered selection*** of k items from a set S is a nonrepeating list of k items from S.

The ***falling power*** $x^{\underline{k}}$ is the product $x(x-1)\dots(x-k+1)$ of k decreasing factors starting at the real number x.

The number ***n-factorial***, $n!$ (n a nonnegative integer), is defined by the rule $0! = 1$, $n! = n(n-1)\dots3{\cdot}2{\cdot}1$ if $n \geq 1$.

A ***permutation of a list*** is any rearrangement of the list.

A ***permutation of a set*** of n items is an arrangement of those items into a list. (Often, such a list and/or the permutation itself is represented by a string whose entries are in the list order.)

A ***k-permutation of a set*** of n items is an ordered selection of k items from that set. A k-permutation can be written as a sequence or a string.

The ***permutation coefficient*** $P(n,k)$ is the number of ways to choose an ordered selection of k items from a set of n items: that is, the number of k-permutations.

A ***derangement of a list*** is a permutation of the entries such that no entry remains in the original position.

Facts:

1. The falling power $x^{\underline{k}}$ is analogous to the ordinary power x^k, which is the product of k constant factors x. The underline in the exponent of the falling power is a reminder that consecutive factors drop.

2. $P(n,k) = n^{\underline{k}} = \frac{n!}{(n-k)!}$.

3. For any integer n, $n^{\underline{n}} = n!$.

4. The numbers $P(n,k) = n^{\underline{k}}$ are given in Table 1.

5. A repetition-free list of length n has approximately $n!/e$ derangements.

Table 1: Permutation coefficients $P(n,k) = n^{\underline{k}}$.

$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10
0	1										
1	1	1									
2	1	2	2								
3	1	3	6	6							
4	1	4	12	24	24						
5	1	5	20	60	120	120					
6	1	6	30	120	360	720	720				
7	1	7	42	210	840	2,520	5,040	5,040			
8	1	8	56	336	1,680	6,720	20,160	40,320	40,320		
9	1	9	72	504	3,024	15,120	60,480	181,440	362,880	362,880	
10	1	10	90	720	5,040	30,240	151,200	604,800	1,814,400	3,628,800	3,628,800

Examples:

1. $(4.2)^{\underline{3}} = 4.2 \cdot 3.2 \cdot 2.2 = 29.568$.

2. *Dealing a row of playing cards*: Suppose that five cards are to be dealt from a deck of 52 cards and placed face up in a row. There are $P(52,5) = 52^{\underline{5}} = 52 \cdot 51 \cdot 50 \cdot 49 \cdot 48 =$ 311,875,200 ways to do this.

3. *Placing distinct balls into distinct bins*: k differently-colored balls are to be placed into n bins ($n \geq k$), with at most one ball to a bin. The number of different ways to arrange the balls is $P(n,k) = n^{\underline{k}}$. (Think of the balls as if they were numbered 1 to k, so that placing ball j into a bin corresponds to placing that bin into the jth position of the list.)

4. *Counting ballots*: Voters are asked to rank their three top choices from the eleven candidates running for office. A first choice vote is worth 3 points, second choice 2 points, and third choice 1 point. Since a completed ballot is an *ordered* selection in this situation, each voter has $P(11,3) = 11^{\underline{3}} = 11 \cdot 10 \cdot 9 = 990$ distinct ways to cast a vote.

5. *License plate combinations*: The license plates in a state have three letters (from the upper-case Roman alphabet of 26 letters) followed by four digits. There are $P(26,3) =$ 15,600 ways to select the letters and $P(10,4) =$ 5,040 ways to select the digits. By the rule of product there are $P(26,3)P(10,4) =$ 15,600 $\cdot$ 5,040 $=$ 78,624,000 strings.

6. *Circular permutations of distinct objects*: See Example 8 of §2.2.1. Also see Example 3 of §2.7.1 for problems that allow identical objects.

7. *Increasing and decreasing subsequences of permutations*: Young tableaux (§2.8) can be used to find the number of permutations of $\{1, 2, \ldots, n\}$ with specified lengths of their longest increasing subsequences and longest decreasing subsequences.

2.3.2 UNORDERED SELECTION: BINOMIAL COEFFICIENTS

Binomial coefficients mathematically model the process of selecting k items from a collection of n items in circumstances where the ordering of the selection does not matter, and repetitions are not allowed.

Definitions:

An ***unordered selection*** of k items from a set S is a subset of k items from S.

A ***k-combination*** from a set S is an unordered selection of k items.

The ***combination coefficient*** $C(n,k)$ is the number of k-combinations of n objects.

The ***binomial coefficient*** $\binom{n}{k}$ is the coefficient of $x^k y^{n-k}$ in the expansion of $(x+y)^n$.

The ***extended binomial coefficient*** (***generalized binomial coefficient***) $\binom{n}{k}$ is zero whenever k is negative. When n is a negative integer and k is a nonnegative integer, its value is $(-1)^k\binom{k-n-1}{k}$.

The ***multicombination coefficient*** $C(n\colon k_1, k_2, \ldots, k_m)$, where $n = k_1 + k_2 + \cdots + k_m$, denotes the number of ways to partition n items into subsets of sizes $k_1, k_2, \ldots, k_m$.

The ***multinomial coefficient*** $\binom{n}{k_1\ k_2\ \ldots\ k_m}$ is the coefficient of $x_1^{k_1}x_2^{k_2}\ldots x_m^{k_m}$ in the expansion of $(x_1 + x_2 + \cdots + x_m)^n$.

The ***Gaussian binomial coefficient*** is defined for nonnegative integers n and k by

$$\begin{bmatrix} n \\ k \end{bmatrix} = \frac{q^n - 1}{q - 1} \cdot \frac{q^{n-1} - 1}{q^2 - 1} \cdot \frac{q^{n-2} - 1}{q^3 - 1} \cdots \frac{q^{n+1-k} - 1}{q^k - 1} \quad \text{for } 0 < k \le n$$

and $\begin{bmatrix} n \\ 0 \end{bmatrix} = 1$, where q is a variable. (See also §2.5.1.)

Facts:

1. $C(n,k) = \frac{P(n,k)}{k!} = \frac{n^{\underline{k}}}{k!} = \frac{n!}{k!(n-k)!} = \binom{n}{k}$.

2. *Pascal's recursion*: $\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k}$, where $n > 0$ and $k > 0$.

3. *Subsets*: There are $C(n,k)$ subsets of size k that can be chosen from a set of size n.

4. The numbers $C(n,k) = \binom{n}{k}$ are given in Table 2.

Table 2: Combination coefficients (binomial coefficients) $C(n,k) = \binom{n}{k}$.

$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10	11	12
0	1												
1	1	1											
2	1	2	1										
3	1	3	3	1									
4	1	4	6	4	1								
5	1	5	10	10	5	1							
6	1	6	15	20	15	6	1						
7	1	7	21	35	35	21	7	1					
8	1	8	28	56	70	56	28	8	1				
9	1	9	36	84	126	126	84	36	9	1			
10	1	10	45	120	210	252	210	120	45	10	1		
11	1	11	55	165	330	462	462	330	165	155	11	1	
12	1	12	66	220	495	792	924	792	495	220	66	12	1

Sometimes the entries in Table 2 are arranged into the form called *Pascal's triangle*, in which each entry is the sum of the two numbers diagonally above the number (Pascal's recursion, Fact 2).

$$\begin{array}{ccccccccccccccccccccc}
&&&&&&&&&&1&&&&&&&&&& \\
&&&&&&&&&1&&1&&&&&&&&& \\
&&&&&&&&1&&2&&1&&&&&&&& \\
&&&&&&&1&&3&&3&&1&&&&&&& \\
&&&&&&1&&4&&6&&4&&1&&&&&& \\
&&&&&1&&5&&10&&10&&5&&1&&&&& \\
&&&&1&&6&&15&&20&&15&&6&&1&&&& \\
&&&1&&7&&21&&35&&35&&21&&7&&1&&& \\
&&1&&8&&28&&56&&70&&56&&28&&8&&1&& \\
&1&&9&&36&&84&&126&&126&&84&&36&&9&&1& \\
1&&10&&45&&120&&210&&252&&210&&120&&45&&10&&1
\end{array}$$

5. The extended binomial coefficients satisfy Pascal's recursion. Their definition is constructed precisely to achieve this purpose.

6. $C(n\colon k_1, k_2, \ldots, k_m) = \frac{n!}{k_1!k_2!\ldots k_m!} = \binom{n}{k_1\ k_2\ \ldots\ k_m}$. The number of strings of length n with k_i objects of type i ($i = 1, 2, \ldots, m$) is $\frac{n!}{k_1!k_2!\ldots k_m!}$.

7. $C(n, k) = C(n\colon k, n-k) = C(n, n-k)$. That is, the number of unordered selections of k objects chosen from n objects is equal to the number of unordered selections of $n-k$ objects chosen from n objects.

8. *Gaussian binomial coefficient identities*:

- $\left[{n \atop k}\right] = \left[{n \atop n-k}\right]$;
- $\left[{n \atop k}\right] + \left[{n \atop k-1}\right]q^{n+1-k} = \left[{n+1 \atop k}\right]$.

9. $(1+x)(1+qx)(1+q^2x)\ldots(1+q^{n-1}x) = \sum_{k=0}^{n} \left[{n \atop k}\right] q^{k(k-1)/2}x^k$.

10. $\lim_{q\to 1} \left[{n \atop k}\right] = \binom{n}{k}$.

11. $\left[{n \atop k}\right] = a_0 + a_1q + a_2q^2 + \cdots + a_{k(n-k)}q^{k(n-k)}$ where each a_i is an integer and $\sum_{i=0}^{k(n-k)} a_i = \binom{n}{k}$.

Examples:

1. *Subsets*: A set with 20 elements has $C(20, 4)$ subsets with four elements. The total number of subsets of a set with 20 elements is equal to $C(20,0)+C(20,1)+\cdots+C(20,20)$, which is equal to 2^{20}. (See §2.3.4.)

2. *Nondistinct balls into distinct bins*: Suppose k identically colored balls are to be placed into n bins ($n \geq k$), at most one ball to a bin. The number of different ways to do this is $C(n, k) = \frac{n^{\underline{k}}}{k!}$. (This amounts to selecting from the n bins the k bins into which the balls are placed.)

3. *Counting ballots*: Each voter is asked to identify three choices for trustee from eleven candidates nominated for the position, without specifying any order of preference. Since a completed ballot is an *unordered* selection in this situation, each voter has $C(11, 3) = \frac{11\cdot 10\cdot 9}{3!} = 165$ distinct ways to cast a vote.

4. *Counting bit strings with exactly k 0s*: There are $\binom{n}{k}$ bit strings of length n with exactly k 0s, since each such bit string is determined by choosing a subset of size k from the n positions; 0s are placed in these k positions, and 1s in the remaining positions.

5. *Counting bit strings with at least k 0s*: There are $\binom{n}{k} + \binom{n}{k+1} + \cdots + \binom{n}{n}$ bit strings of length n with at least k 0s, since each such bit string is determined by choosing a subset of size $k, k+1, \ldots,$ or n from the n positions; 0s are placed in these positions, and 1s in the remaining positions.

6. *Counting bit strings with equal numbers of* 0s *and* 1s: For n even, there are $\binom{n}{n/2}$ bit strings of length n with equal numbers of 0s and 1s, since each such bit string is determined by choosing a subset of size $\frac{n}{2}$ from the n positions; 0s are placed in these positions, and 1s in the remaining positions.

7. *Counting strings with repeated letters*: The word "MISSISSIPPI" has eleven letters, with "I" and "S" appearing four times each, "P" appearing twice, and "M" once. There are $C(11\colon 4,4,2,1) = \frac{11!}{4!4!2!1!} = 34{,}650$ possible different strings obtainable by permuting the letters. This counting problem is equivalent to partitioning 11 items into subsets of sizes 4, 4, 2, 1.

8. *Counting circular strings with repeated letters*: See §2.7.1.

9. *Counting paths*: The number of paths in the plane from $(0,0)$ to a point (m,n) $(m,n \geq 0)$ that move one unit upward or one unit to the right at each step is $\binom{m+n}{n}$. Using U for "up" and R for "right", each path can be described by a string of m Rs and n Us.

10. *Playoff series*: In a series of playoff games, such as the World Series or Stanley Cup finals, the winner is the first team to win more than half the maximum number of games possible, n (odd). The winner must win $\frac{n+1}{2}$ games. The number of possible win-loss sequences of such a series is $2C(n, \frac{n+1}{2})$. For example, in the World Series between teams A and B, any string of length 7 with exactly 4 As represents a winning sequence for A. (The string $AABABBA$ means that A won a seven-game series by winning the first, second, fourth, and seventh games; the string $AAAABBB$ means that A won the series by winning the first four games.) There are $C(7,4)$ ways for A to win the World Series, and $C(7,4)$ ways for B to win the World Series.

11. *Dealing a hand of playing cards*: A hand of five cards (where order does not matter) can be dealt from a deck of 52 cards in $C(52,5) = \frac{52^{\underline{5}}}{5!} = 2{,}598{,}960$ ways.

12. *Poker hands*: Table 3 contains the number of combinations of five cards that form various poker hands (where an ace can be high or low).

13. *Counting partial functions*: There are $\binom{k}{0} + \binom{k}{1}n + \binom{k}{2}n^2 + \cdots + \binom{k}{k}n^k$ partial functions $f\colon A \to B$ where $|A| = k$ and $|B| = n$. Each partial function is determined by choosing a domain of definition for the function, which can be done, for each $j = 0, \ldots, n$, in $\binom{k}{j}$ ways. Once a domain of definition is determined, there are n^j ways to define a function on that set. (The sum can be simplified to $(n+1)^k$.)

14. $\left[\begin{smallmatrix}3\\1\end{smallmatrix}\right] = \frac{q^3-1}{q-1} = 1 + q + q^2$.

15. $\left[\begin{smallmatrix}6\\2\end{smallmatrix}\right] = \frac{q^6-1}{q-1} \cdot \frac{q^5-1}{q^2-1} = \frac{q^6-1}{q^2-1} \cdot \frac{q^5-1}{q-1} = (q^4+q^2+1)(q^4+q^3+q^2+q+1) = 1 + q + 2q^2 + 2q^3 + 3q^4 + 2q^5 + 2q^6 + q^7 + q^8$. The sum of these coefficients is $15 = \binom{6}{2}$, as Fact 11 predicts.

16. A particle moves in the plane from $(0,0)$ to $(n-k,k)$ by moving one unit at a time in either the positive x or positive y direction. The number of such paths where the area bounded by the path, the x-axis, and the vertical line $x = n-k$ is i units is equal to a_i, where a_i is the coefficient of q^i in the expansion of the Gaussian binomial coefficient $\left[\begin{smallmatrix}n\\k\end{smallmatrix}\right]$ in Fact 11.

Table 3: Number of poker hands.

type of hand	*formula*	*explanation*
royal flush (ace, king, queen, jack, 10 in same suit)	4	4 choices for a suit, and 1 royal flush in each suit
straight flush (5 cards of five consecutive ranks, all in one suit, but not a royal flush)	$\binom{4}{1}9$	4 choices for a suit, and in each suit there are 9 ways to get five cards in a row
four of a kind (4 cards in one rank and a fifth card)	$\binom{13}{1}\binom{48}{1}$	13 choices for a rank, only 1 way to select the four cards in that rank, and 48 ways to select a fifth card
full house (3 cards of one rank, 2 of another rank)	$13\binom{4}{3}12\binom{4}{2}$	13 ways to select a rank for the 3-of-a-kind, and $\binom{4}{3}$ ways to choose 3 of this rank; 12 ways to select a rank for the pair, and $\binom{4}{2}$ ways to get a pair of this rank
flush (5 cards in one suit, but neither royal nor straight flush)	$4\binom{13}{5}-4\cdot 10$	4 ways to select a suit, $\binom{13}{5}$ ways to choose five cards in that suit; then subtract royal and straight flushes
straight (5 cards in five consecutive ranks, but not all of the same suit)	$10\cdot 4^5-4\cdot 10$	10 ways to choose five ranks in a row, and 4 ways to choose a card from each rank; then subtract royal and straight flushes
three of a kind (3 cards of one rank, and 2 cards of two different ranks)	$13\binom{4}{3}\binom{12}{2}4^2$	13 ways to select one rank, $\binom{4}{3}$ ways to choose 3 cards of that rank; $\binom{12}{2}$ ways to pick two other ranks; and 4^2 ways to pick a card of each of those two ranks
two pairs (2 cards in each of two different ranks, and a fifth card of a third rank)	$\binom{13}{2}\binom{4}{2}\binom{4}{2}44$	$\binom{13}{2}$ ways to select two ranks, $\binom{4}{2}$ ways to choose 2 cards in each of these ranks, and $\binom{44}{1}$ way to pick a nonmatching fifth card
one pair (2 cards in one rank, plus 3 cards from three other ranks)	$13\binom{4}{2}\binom{12}{3}4^3$	13 ways to select a rank, $\binom{4}{2}$ ways to choose two cards in that rank; $\binom{12}{3}$ ways to pick three other ranks, and 4^3 ways to pick one card from each of those ranks

2.3.3 SELECTION WITH REPETITION

Some problems concerning counting the number of ways to select k objects from a set of n objects permit choices of objects to be repeated. Some of these situations are also modeled by binomial coefficients.

Definitions:

An ***ordered selection with replacement*** is an ordered selection in which each object in the selection set can be chosen arbitrarily often.

An ***ordered selection with specified replacement*** fixes the number of times each object is to be chosen.

An ***unordered selection with replacement*** is a selection in which each object in the selection set can be chosen arbitrarily often.

The ***permutation-with-replacement coefficient*** $P^R(n,k)$ is the number of ways to choose a possibly repeating list of k items from a set of n items.

The ***combination-with-replacement coefficient*** $C^R(n,k)$ is the number of ways to choose a multiset of k items from a set of n items.

Facts:

1. An ordered selection with replacement can be thought of as obtaining an ordered list of names, obtained by selecting an object from a set, writing its name, placing it back in the set, and repeating the process.

2. The number of ways to make an ordered selection with replacement of k items from n distinct items (with arbitrary repetition) is n^k. Thus $P^R(n,k) = n^k$.

3. The number of ways to make an ordered selection of n items from a set of q distinct items, with exactly k_i selections of object i, is $\frac{n!}{k_1!k_2!\ldots k_q!}$.

4. An unordered selection with replacement can be thought of as obtaining a collection of names, obtained by selecting an object from a set, writing its name, placing it back in the set, and repeating the process. The resulting collection is a multiset (§1.2.1).

5. The number of ways to make an unordered selection with replacement of k items from a set of n items is $C(n+k-1,k)$. Thus $C^R(n,k) = C(n+k-1,k)$.

Combinatorial interpretation: It is sufficient to show that the k-multisets that can be chosen from a set of n items are in one-to-one correspondence with the bit strings of length $(n+k-1)$ with k ones. To indicate that k_j copies of item j are selected, for $j = 1,\ldots,n$, write a string of k_1 ones, then a "0", then a string of k_2 ones, then another "0", then a string of k_3 ones, then another "0", and so on, until after the string of k_{n-1} ones and the last "0", there appears the final string of k_n ones. The resulting bit string has length $n+k-1$ (since it has k ones and $n-1$ zeros). Every such bit string describes a possible selection. Thus the number of possible selections is $C(n+k-1,k) = C(n+k-1,n-1)$.

6. *Integer solutions to the equation* $x_1 + x_2 + \cdots + x_n = k$:

- The number of nonnegative integer solutions is $C(n+k-1,k) = C(n+k-1,n-1)$. [In the combinatorial argument of Fact 5, there are n strings of ones. The first string of ones can be regarded as the value for x_1, the second string of ones as the value for x_2, etc.]
- The number of positive integer solutions is $C(k-1,n-1)$.
- The number of nonnegative integer solutions where $x_i \geq a_i$ for $i = 1,\ldots,n$ is $C(n+k-1-(a_1+\cdots+a_n), n-1)$ (if $a_1+\cdots+a_n \leq k$). [Let $x_i = y_i + a_i$ for each i, yielding the equation $y_1+y_2+\cdots+y_n = k-(a_1+\cdots+a_n)$ to be solved in nonnegative integers.]
- The number of nonnegative integer solutions where $x_i \leq a_i$ for $i = 1,\ldots,n$ can be obtained using the inclusion/exclusion principle. See §2.4.2.

Examples:

1. *Distinct balls into distinct bins*: k differently colored balls are to be placed into n bins, with arbitrarily many balls to a bin. The number of different ways to do this is n^k. (Apply the rule of product to the number of possible bin choices for each ball.)

2. *Binary strings*: The number of sequences (bit strings) of length n that can be constructed from the symbol set $\{0, 1\}$ is 2^n.

3. *Colored balls into distinct bins with colors repeated*: k balls are colored so that k_1 balls have color 1, k_2 have color 2, ..., and k_q have color q. The number of ways these k balls can be placed into n distinct bins ($n \geq k$), at most one per bin, is $\frac{P(n,k)}{k_1!k_2!\ldots k_q!}$.

Note: This is more general than Fact 2, since n can exceed the sum of all the k_is. If n equals this sum, then $P(n, n) = n!$ and the two formulas agree.

4. When three dice are rolled, the "outcome" is the number of times each of the numbers 1 to 6 appears. For instance, two 3s and a 5 is an outcome. The number of different possible outcomes is $C(6 + 3 - 1, 3) = \binom{8}{3} = 56$.

5. *Nondistinct balls into distinct bins with multiple balls per bin allowed*: The number of ways that k identical balls can be placed into n distinct bins, with any number of balls allowed in each bin, is $C(n + k - 1, k)$.

6. *Nondistinct balls into distinct bins with no bin allowed to be empty*: The number of ways that k identical balls can be placed into n distinct bins, with any number of balls allowed in each bin and no bin allowed to remain empty, is $C(k - 1, n - 1)$.

7. How many ways are there to choose one dozen donuts when there are 7 different kinds of donuts, with at least 12 of each type available? Order is not important, so a multiset of size 12 is being constructed from 7 distinct types. Accordingly, there are $C(7 + 12 - 1, 12) = 18{,}564$ ways to choose the dozen donuts.

8. The number of nonnegative integer solutions to the equation $x_1 + x_2 + \cdots + x_7 = 12$ is $C(7 + 12 - 1, 12)$, since this is a rephrasing of Example 7.

9. The number of nonnegative integer solutions to $x_1 + x_2 + \cdots + x_5 = 36$, where $x_1 \geq 4$, $x_3 = 11$, and $x_4 \geq 7$ is $C(17, 3)$. [It is easiest to think of purchasing 36 donuts, where at least 4 of type 1, exactly 11 of type 3, and at least 7 of type 4 must be purchased. Begin with an empty bag, and put in 4 of type 1, 11 of type 3, and 7 of type 4. This leaves 14 donuts to be chosen, and they must be of types 1, 2, 4, or 5, which is equivalent to finding the number of nonnegative integer solutions to $x_1 + x_2 + x_4 + x_5 = 14$.]

2.3.4 BINOMIAL COEFFICIENT IDENTITIES

Facts:

1. Table 4 lists some identities involving binomial coefficients.

2. Combinatorial identities, such as those in Table 4, can be proved algebraically by using techniques such as substitution, differentiation, or the principle of mathematical induction (see Facts 4 and 5); they can also be proved by using combinatorial proofs. (See Fact 3.)

Table 4: Binomial coefficient identities.

Factorial expansion	$\binom{n}{k} = \frac{n!}{k!(n-k)!}$, $k = 0, 1, 2, \ldots, n$
Symmetry	$\binom{n}{k} = \binom{n}{n-k}$, $k = 0, 1, 2, \ldots, n$
Monotonicity	$\binom{n}{0} < \binom{n}{1} < \cdots < \binom{n}{\lfloor n/2 \rfloor}$, $n \geq 0$
Pascal's identity	$\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k}$, $k = 0, 1, 2, \ldots, n$
Binomial theorem	$(x+y)^n = \sum_{k=0}^{n} \binom{n}{k} x^k y^{n-k}$, $n \geq 0$
Counting all subsets	$\sum_{k=0}^{n} \binom{n}{k} = 2^n$, $n \geq 0$
Even and odd subsets	$\sum_{k=0}^{n} (-1)^k \binom{n}{k} = 0$, $n \geq 0$
Sum of squares	$\sum_{k=0}^{n} \binom{n}{k}^2 = \binom{2n}{n}$, $n \geq 0$
Square of row sums	$\left[\sum_{k=0}^{n} \binom{n}{k}\right]^2 = \sum_{k=0}^{2n} \binom{2n}{k}$, $n \geq 0$
Absorption/extraction	$\binom{n}{k} = \frac{n}{k} \binom{n-1}{k-1}$, $k \neq 0$
Trinomial revision	$\binom{n}{m}\binom{m}{k} = \binom{n}{k}\binom{n-k}{m-k}$, $0 \leq k \leq m \leq n$
Parallel summation	$\sum_{k=0}^{m} \binom{n+k}{k} = \binom{n+m+1}{m}$, $m, n \geq 0$
Diagonal summation	$\sum_{k=0}^{n-m} \binom{m+k}{m} = \binom{n+1}{m+1}$, $n \geq m \geq 0$
Vandermonde convolution	$\sum_{k=0}^{r} \binom{m}{k}\binom{n}{r-k} = \binom{m+n}{r}$, $m, n, r \geq 0$
Diagonal sums in Pascal's triangle (§2.3.2)	$\sum_{k=0}^{\lfloor n/2 \rfloor} \binom{n-k}{k} = F_{n+1}$ *(Fibonacci numbers)*, $n \geq 0$
Other common identities	$\sum_{k=0}^{n} k\binom{n}{k} = n2^{n-1}$, $n \geq 0$
	$\sum_{k=0}^{n} k^2\binom{n}{k} = n(n+1)2^{n-2}$, $n \geq 0$
	$\sum_{k=0}^{n} (-1)^k k\binom{n}{k} = 0$, $n \geq 0$
	$\sum_{k=0}^{n} \frac{\binom{n}{k}}{k+1} = \frac{2^{n+1}-1}{n+1}$, $n \geq 0$
	$\sum_{k=0}^{n} (-1)^k \frac{\binom{n}{k}}{k+1} = \frac{1}{n+1}$, $n \geq 0$
	$\sum_{k=1}^{n} (-1)^{k-1} \frac{\binom{n}{k}}{k} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n}$, $n > 0$
	$\sum_{k=0}^{n-1} \binom{n}{k}\binom{n}{k+1} = \binom{2n}{n-1}$, $n > 0$
	$\sum_{k=0}^{m} \binom{m}{k}\binom{n}{p+k} = \binom{m+n}{m+p}$, $m, n, p \geq 0$, $n \geq p + m$

3. The following give combinatorial interpretations of some of the identities involving binomial coefficients in Table 4.

- *Symmetry*: In choosing a subset of k items from a set of n items, the number of ways to select which k items to include must equal the number of ways to select which $n-k$ items to exclude.
- *Pascal's recursion*: In choosing k objects from a list of n distinct objects, the number of ways that include the last object is $\binom{n-1}{k-1}$, and the number of ways that exclude the last object is $\binom{n-1}{k}$. Their sum is then the total number of ways to choose k objects from a set of n, namely $\binom{n}{k}$.
- *Binomial theorem*: The coefficient of $x^k y^{n-k}$ in the expansion $(x+y)^n = (x+y)(x+y)\ldots(x+y)$ equals the number of ways to choose k factors from among the n factors $(x+y)$ in which x contributes to the resultant term.
- *Counting all subsets*: Summing the numbers of subsets of all possible sizes yields the total number of different possible subsets.
- *Sum of squares*: Choose a committee of size n from a group of n men and n women. The left side, rewritten as $\binom{n}{k}\binom{n}{n-k}$, describes the process of selecting committees according to the number of men, k, and the number of women, $n-k$, on the committee. The right side gives the total number of committees possible.

- *Absorption/extraction*: From a group of n people, choose a committee of size k and a person on the committee to be its chairperson. Equivalently, first select a chairperson from the entire group, and then select the remaining $k-1$ committee members from the remaining $n-1$ people.
- *Trinomial revision*: The left side describes the process of choosing a committee of size m from n people and then a subcommittee of size k. The right side describes the process where the subcommittee of size k is first chosen from the n people and then the remaining $m-k$ members of the committee are selected from the remaining $n-k$ people.
- *Vandermonde convolution*: Given m men and n women, form committees of size r. The summands give the numbers of committees broken down by number of men, k, and number of women, $r-k$, on the committee; the right side gives the total number of committees.

4. The formula for counting all subsets can be obtained from the binomial theorem by substituting 1 for x and 1 for y.

5. The formula for even and odd subsets can be obtained from the binomial theorem by substituting 1 for x and -1 for y.

6. A set A of size n has 2^{n-1} subsets with an even number of elements and 2^{n-1} subsets with an odd number of elements. (The *even and odd subsets* identity in Table 4 shows that $\sum \binom{n}{k}$ for k even is equal to $\sum \binom{n}{k}$ for k odd. Since the total number of subsets is 2^n, each side must equal 2^{n-1}.)

2.3.5 GENERATING PERMUTATIONS AND COMBINATIONS

There are various systematic ways to generate permutations and combinations of the set $\{1, \ldots, n\}$.

Definitions:

A list of strings from an ordered set is in ***lexicographic order*** if the strings are sorted as they would appear in a dictionary.

If the elements in the strings are ordered by a relation $<$, string $a_1a_2\ldots a_m$ ***precedes*** $b_1b_2\ldots b_n$ if any of the following happens: $a_1 < b_1$; there is a positive integer k such that $a_1 = b_1, \ldots, a_k = b_k$ and $a_{k+1} < b_{k+1}$; or $m < n$ and $a_1 = b_1, \ldots, a_m = b_m$.

Algorithms:

Here k is a given positive integer less than or equal to n and $r(k)$ is a randomly chosen integer in the range $\{1, 2, \ldots, k\}$ Algorithms 1, 2, and 5 give ways to generate all permutations, k-permutations, and k-combinations of $\{1, 2, \ldots, n\}$ in lexicographic order. Algorithms 3, 4, and 6 give ways to randomly generate a permutation, k-permutation, and k-combination of $\{1, 2, \ldots, n\}$.

Algorithm 1: **Generate permutations of $\{1, \ldots, n\}$ in lexicographic order**

```
$a_1a_2\ldots a_n := 1\,2\,\ldots\,n$
while $a_1a_2\ldots a_n \neq n\;n{-}1\;\ldots\;1$
    $m :=$ the rightmost location such that $a_m$ is followed by a larger number
    $a'_1a'_2\ldots a'_{m-1} := a_1a_2\ldots a_{m-1}$    {Retain everything to the left of $a_m$}
    $a'_m$ := the smallest number larger than $a_m$ to the right of $a_m$
    $a'_{m+1}a'_{m+2}\dots a'_n$ := everything else, in ascending order
    $a_1a_2\dots a_n := a'_1a'_2\dots a'_n$
    output $a_1a_2\dots a_n$
```

```
Algorithm 2: Generate $k$-permutations of $\{1,\dots,n\}$ in lexicographic order
  $a_1a_2\dots a_k := 1\,2\,\dots\,k$
  while $a_1a_2\dots a_k \neq n\ n{-}1\ \dots\ n-(k-1)$
    $m$ := the rightmost location such that $a_m$ is followed by a larger number
    $a'_1a'_2\dots a'_{m-1} := a_1a_2\dots a_{m-1}$   {Retain everything to the left of $a_m$}
    $a'_m$ := the smallest number larger than $a_m$ to the right of $a_m$
    $a'_{m+1}a'_{m+2}\dots a'_k$ := everything else, in ascending order
    $a_1a_2\dots a_k := a'_1a'_2\dots a'_k$
    output $a_1a_2\dots a_k$
```

```
Algorithm 3: Generate a random permutation of $\{1,\dots,n\}$.
  $a_1a_2\dots a_n := 1\,2\,\dots\,n$
  for $i := 0$ to $n-2$
    interchange $a_{n-i}$ and $a_{r(n-i)}$
  output $a_1a_2\dots a_n$
```

```
Algorithm 4: Generate a random $k$-permutation of $\{1,\dots,n\}$.
  $a_1a_2\dots a_n$ := a random permutation of $\{1,\dots,n\}$ generated from Algorithm 3
  output $a_1a_2\dots a_k$
```

```
Algorithm 5: Generate $k$-combinations of $\{1,\dots,n\}$ in lexicographic order.
  $a_1a_2\dots a_k := 1\,2\,\dots\,k$   {First combination in lexicographic order}
  while $a_1a_2\dots a_k \neq n{-}k{+}1\ n{-}k{+}2\ \dots\ n$
    $m$ := the rightmost location among $1,\dots,k$ such that a number larger than
      $a_m$ but smaller than $n$ is not in the combination
    $a'_1a'_2\dots a'_{m-1} := a_1a_2\dots a_{m-1}$   {Retain everything to the left of $a_m$}
    $a'_m := a_m + 1$
    $a'_{m+1}\,a'_{m+2}\ \dots\ a'_k := a_m{+}2\ a_m{+}3\dots a_m{+}k{-}m{+}1$   {Continue consecutively}
    output $a_1a_2\dots a_k := a'_1a'_2\dots a'_k$
```

```
Algorithm 6: Generate a random $k$-combination of $\{1,\dots,n\}$.
  $a_1a_2\dots a_k$ := a $k$-permutation of $\{1,\dots,n\}$ generated by Algorithm 4
  output $a_1a_2\dots a_k$   {Ignore the order in which elements are written}
```

Examples:

1. The lexicographic order for the 3-permutations of $\{1,2,3\}$ is 123, 132, 213, 231, 312, 321.

2. The lexicographic order of the $C(5,3) = 10$ 3-combinations of $\{1,2,3,4,5\}$ is 123, 124, 125, 134, 135, 145, 234, 235, 245, 345.

3. *Generating permutations*: What permutation follows 3142765 in the lexicographic ordering of the permutations of $\{1,\ldots,7\}$? Step 1 of the while-loop of Algorithm 1 leads to the fourth digit, namely the digit 2, as the first digit from the right that has larger digits following it. Steps 2 and 3 show that the next permutation starts with 3145 since 5 is the smallest digit greater than 2 and following it. Finally, Step 4 yields 2, 6, and 7 (in numerical order) as the digits that follow. Thus, the permutation immediately following 3142765 is 3145267.

4. *Generating combinations*: What 5-combination follows 12478 in the lexicographic ordering of 5-combinations of $\{1,\ldots,8\}$? Step 1 of the while-loop of Algorithm 5 leads to the third digit, namely the digit 4, as the first digit from the right that can be safely increased by 1. Step 2 shows that the next permutation starts with 125 since the third digit is increased by 1. Finally, Step 3 yields 6 and 7 as the following digits (add 1 to the newly-listed previous digit until the new selection of k digits is complete). Thus, the combination after 12478 is 12567.

2.4 INCLUSION/EXCLUSION

The principle of inclusion/exclusion is used to count the elements in a non-disjoint union of finite sets. Many counting problems can be solved by applying this principle to a well-chosen collection of sets. The techniques involved in this process are best illustrated with examples.

2.4.1 PRINCIPLE OF INCLUSION/EXCLUSION

The number of elements in the union of two finite sets A and B is $|A| + |B|$, provided that the sets have no element in common. In the general case, however, some elements in common to both sets have been included in the sum twice. The sum is adjusted to exclude the double-counting of these common elements by subtracting their number:

$$|A \cup B| = |A| + |B| - |A \cap B|.$$

Similarly, the number of elements in the union of three finite sets is

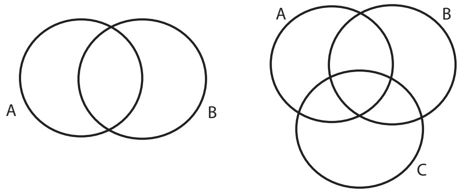
$$|A \cup B \cup C| = |A| + |B| + |C| - |A \cap B| - |A \cap C| - |B \cap C| + |A \cap B \cap C|.$$

The following Venn diagram (§1.2.2) illustrates these two cases. These simple equations generalize to the case of n sets.

Facts:

1. *Inclusion/exclusion principle*: The number of elements in the union of n finite sets $A_1, A_2, \ldots, A_n$ is

$$\begin{aligned} |A_1 \cup A_2 \cup \cdots \cup A_n| &= \sum_{1 \le i \le n} |A_i| - \sum_{1 \le i < j \le n} |A_i \cap A_j| + \sum_{1 \le i < j < k \le n} |A_i \cap A_j \cap A_k| \\ &\quad - \cdots + (-1)^{n+1} |A_1 \cap A_2 \cap \cdots \cap A_n| \end{aligned}$$



or, alternatively,

$$|A_1 \cup A_2 \cup \cdots \cup A_n| = \sum_{k=1}^{n} (-1)^{k+1} \sum_{1 \le i_1 < \cdots < i_k \le n} |A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}|\,.$$

Sometimes the inner sum of the alternative formula is denoted S_k.

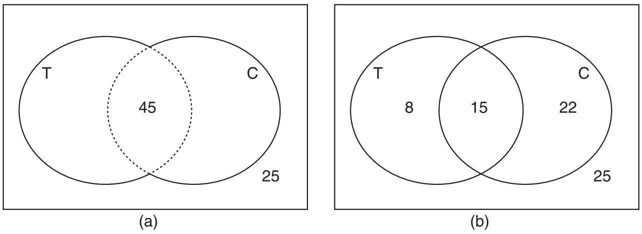
2. The inclusion/exclusion formula for n sets has $2^n - 1$ terms, one for each possible nonempty intersection. The coefficient of a term is -1 if the term corresponds to intersections of an even number of sets, and $+1$ otherwise.

3. The principle is often applied to the complement of a set. Let A_i be the subset of elements in a universal set U that have property P_i. The number of elements that have properties $P_{i_1}, P_{i_2}, \ldots, P_{i_k}$ is often written $N(P_{i_1}P_{i_2}\ldots P_{i_k})$ and the number of elements that have none of these properties is often written $N(P'_{i_1}P'_{i_2}\ldots P'_{i_k})$. The number of elements in U that have none of the properties is

$$N(P'_1P'_2\ldots P'_n) = |U| - \sum_{1\le i\le n} N(P_i) + \sum_{1\le i<j\le n} N(P_iP_j) - \cdots + (-1)^n N(P_1P_2\ldots P_n).$$

Examples:

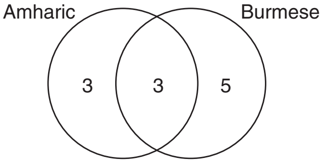
1. Of 70 people surveyed, 37 drink coffee, 23 drink tea, and 25 drink neither. Find the number who drink both coffee and tea. Using C to represent the set of coffee drinkers and T to represent the set of tea drinkers, the size of $C \cap T$ must be found. Since $|\overline{T \cup C}| = 25$, the Venn diagram in part (a) of the following figure shows that $|C \cup T| = 45$. According to the inclusion/exclusion principle, $|C \cap T| = |C| + |T| - |C \cup T| = 37 + 23 - 45 = 15$, illustrated in part (b) of the figure.



2. Suppose that 16 high-school juniors enroll in Algebra, 17 in Biology, and 30 in Chemistry; that 5 students enroll in both Algebra and Biology, 4 in both Algebra and Chemistry, and 7 in both Biology and Chemistry; that 3 students enroll in all three; and that every junior takes at least one of these three subjects. Then the total number of students in the junior class is $16 + 17 + 30 - (5 + 4 + 7) + 3 = 50$.

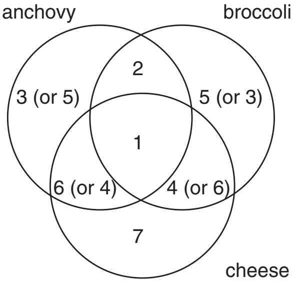
3. Each of 11 linguists translates at least one of the languages Amharic and Burmese into English. The numbers who translate only Amharic or Burmese are both odd primes. More linguists translate Burmese than Amharic. How many can translate Amharic?

Based on experimentation or on an analytic approach, the only possible assignment of numbers to regions that fits all these facts leads to 6, as shown in the following figure.



4. At a party for 28 people, three kinds of pizza were served: anchovy, broccoli, and cheese. Everyone ate at least one kind. No two of the seven different possible selections of one or more kinds of pizza were eaten by the same number of partygoers. Each of the three possible exclusive selections (one kind of pizza only) was eaten by an odd number of partygoers, and each of the three possible combinations of two kinds of pizza was eaten by an even number of partygoers. If a total of 18 partygoers ate cheese pizza, how many ate both anchovy and broccoli?

The answer is 2. Experimentation or an analytic approach leads to the possible assignments of numbers to regions that fit all these facts, shown in the following figure.



5. To count the number of ways to select a 5-card hand from a standard 52-card deck so that the hand contains at least one card from each of the four suits, let A_1, A_2, A_3, and A_4 be the subsets of 5-card hands that do not contain a club, diamond, heart, or spade, respectively. Then

$$\begin{aligned}|A_i| &= \tbinom{52-13}{5} = \tbinom{39}{5} && \text{with } \tbinom{4}{1} \text{ choices for } i\\ |A_i \cap A_j| &= \tbinom{52-26}{5} = \tbinom{26}{5} && \text{with } \tbinom{4}{2} \text{ choices for } i \text{ and } j\\ |A_i \cap A_j \cap A_k| &= \tbinom{52-39}{5} = \tbinom{13}{5} && \text{with } \tbinom{4}{3} \text{ choices for } i,\ j, \text{ and } k.\end{aligned}$$

There are $\binom{52}{5}$ possible 5-card hands, so by complementation and the principle of inclusion/exclusion, those that contain at least one card from each suit is

$$\tbinom{52}{5} - \tbinom{4}{1}\tbinom{39}{5} + \tbinom{4}{2}\tbinom{26}{5} - \tbinom{4}{3}\tbinom{13}{5} = 685{,}464.$$

2.4.2 APPLYING INCLUSION/EXCLUSION TO COUNTING PROBLEMS

Definitions:

A ***derangement*** on a set is a permutation that leaves no element fixed. The number of derangements on a set of cardinality n is denoted D_n.

A ***rencontre number*** $D_{n,k}$ is the number of permutations on a set of n elements that leave exactly k elements fixed.

Facts:

1. The number of onto functions from an n-element set to a k-element set ($n \geq k$) is

$$\textstyle\sum_{j=0}^{k}(-1)^j\binom{k}{j}(k-j)^n$$

(See Example 3.)

2. The following binomial coefficient identities can all be derived by combinatorial arguments using inclusion/exclusion:

- $\sum_{k=0}^{m}(-1)^k\binom{n}{k}\binom{n-k}{m-k} = 0$
- $\sum_{k=m}^{n}(-1)^{k-m}\binom{n}{k} = \binom{n-1}{m-1}$
- $\sum_{k=0}^{n}(-1)^k\binom{n}{k}(\frac{n-k+r-1}{r}) = \binom{r-1}{n-1}$.

3. $D_n = n!(1 - \frac{1}{1!} + \frac{1}{2!} - \cdots + (-1)^n\frac{1}{n!})$. (See Example 8.)

4. $\frac{D_n}{n!} \to e^{-1} \approx 0.368$ as $n \to \infty$.

5. $D_n = nD_{n-1} + (-1)^n$ for $n \geq 1$.

6. $D_n = (n-1)(D_{n-1} + D_{n-2})$ for $n \geq 2$.

7. The following table gives some values of D_n:

n	D_n	n	D_n	n	D_n	n	D_n
1	0	4	9	7	1,854	10	1,334,961
2	1	5	44	8	14,833	11	14,684,570
3	2	6	265	9	133,496	12	176,214,841

8. $D_{n,0} = D_n$.

9. $D_{n,k} = \binom{n}{k}D_{n-k}$

10. The following table gives some values of $D_{n,k}$:

$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10
0	1										
1	0	1									
2	1	0	1								
3	2	3	0	1

Examples:

1. The inclusion/exclusion principle can be used to establish the binomial coefficient identity

$$\binom{n}{m} = \sum_{k=1}^{m}(-1)^{k+1}\binom{n-k}{m-k}\binom{n}{k}.$$

Let A_i denote the subset of m-combinations that contain object i. Thus, the k-fold intersection $A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}$ consists of all the m-combinations that contain all the objects $i_1, i_2, \ldots, i_k$. Since there are $\binom{n-k}{m-k}$ ways to complete an m-combination in this intersection, it follows that $|A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}| = \binom{n-k}{m-k}$. Since the k objects themselves can be specified in $\binom{n}{k}$ ways, it follows that

$$\sum_{1 \le i_1 < i_2 < \cdots < i_k \le n} |A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}| = \binom{n-k}{m-k}\binom{n}{k}, \qquad k \le m.$$

Since $A_1 \cup A_2 \cup \cdots \cup A_n$ is the set of all m-combinations selected from $1, 2, \ldots, n$ that contain at least one of the objects $1, 2, \ldots, n$, it must be the set of all m-combinations.

2. *Sieve of Eratosthenes*: The sieve of Eratosthenes (276–194 BCE) is a method for finding all primes less than or equal to a given positive integer n. Begin with the list of integers 2 through n, and delete all multiples of the first number in the list, 2, but not including 2. The first integer remaining after 2 is 3; delete all multiples of 3, not including 3. The first integer remaining after 3 is 5; delete all multiples of 5, not including 5. Continue the process. The remaining integers are the primes less than or equal to n. (See §4.4.2.)

The inclusion/exclusion principle can be used to obtain the number of primes less than or equal to n. (A number $x \le n$ is *prime* if and only if x has a prime factor less than or equal to $\lfloor \sqrt{n} \rfloor$.) Let P_i be the property: a number is greater than the ith prime and divisible by the ith prime. Then the number of primes less than or equal to n is $N(P_1'P_2' \ldots P_k')$, where there are k primes less than or equal to $\lfloor \sqrt{n} \rfloor$. (§2.4.1, Fact 3.)

For example, the number of primes less than or equal to 100 is $N(P_1'P_2'P_3'P_4') = 99 - \lfloor \frac{100}{2} \rfloor - \lfloor \frac{100}{3} \rfloor - \lfloor \frac{100}{5} \rfloor - \lfloor \frac{100}{7} \rfloor + \lfloor \frac{100}{2\cdot3} \rfloor + \lfloor \frac{100}{2\cdot5} \rfloor + \lfloor \frac{100}{2\cdot7} \rfloor + \lfloor \frac{100}{3\cdot5} \rfloor + \lfloor \frac{100}{3\cdot7} \rfloor + \lfloor \frac{100}{5\cdot7} \rfloor - \lfloor \frac{100}{2\cdot3\cdot5} \rfloor - \lfloor \frac{100}{2\cdot3\cdot7} \rfloor - \lfloor \frac{100}{2\cdot5\cdot7} \rfloor - \lfloor \frac{100}{3\cdot5\cdot7} \rfloor + \lfloor \frac{100}{2\cdot3\cdot5\cdot7} \rfloor = 99 - 50 - 33 - 20 - 14 + 16 + 10 + 7 + 6 + 4 + 2 - 3 - 2 - 1 - 0 + 0 = 21$.

3. *Number of onto functions*: The number of onto functions from an n-element set to a k-element set ($n \ge k$) is $\sum_{j=0}^{k} (-1)^j \binom{k}{j} (k-j)^n$. The number of onto functions from an n-element set to a k-element set equals the number of ways that n different objects can be distributed among k different boxes with none left empty. Let A_i be the subset of distributions with box i empty. Then

$$\begin{aligned} |A_i| &= (k-1)^n && \text{with } \tbinom{k}{1} \text{ choices for } i \\ |A_i \cap A_j| &= (k-2)^n && \text{with } \tbinom{k}{2} \text{ choices for } i \text{ and } j \\ &\;\vdots \\ |A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}| &= (k-k)^n && \text{with } \tbinom{k}{k} \text{ choices for } i_1, i_2, \ldots, i_k. \end{aligned}$$

The number of distributions that leave no box empty is then $\sum_{j=0}^{k} (-1)^j \binom{k}{j} (k-j)^n$.

The number of onto functions from an n-element set to a k-element set for some values of n and k ($n \ge k$) are given in the following table:

$n \backslash k$	1	2	3	4	5	6	7	8	9
1	1								
2	1	2							
3	1	6	6						
4	1	14	36	24					
5	1	30	150	240	120				
6	1	62	540	1560	1800	720			
7	1	126	1806	8400	16,800	15,120	5,040		
8	1	254	5796	40,824	126,000	191,520	141,120	40,320	
9	1	510	18,150	186,480	834,120	1,905,120	2,328,480	1,451,520	362,880

4. There are 584 nonnegative integer solutions to $x_1 + x_2 + x_3 + x_4 = 20$ where $x_1 \le 8$, $x_2 \le 10$, and $x_3 \le 5$. [Let A_1 be the set of solutions where $x_1 \ge 9$, A_2 the set of solutions where $x_2 \ge 11$, and A_3 the set of solutions where $x_3 \ge 6$. The final answer, obtained using the inclusion/exclusion principle and the techniques used in the examples of §2.3.3, is equal to $C(23,3) - |A_1 \cup A_2 \cup A_3| = C(23,3) - (C(14,3) + C(12,3) + C(17,3) - C(3,3) - C(8,3) - C(6,3) + 0) = 584$.]

5. The permutations $\left(\begin{smallmatrix}1&2&3\\2&3&1\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}1&2&3\\3&1&2\end{smallmatrix}\right)$ are derangements of $1, 2, 3$, but the permutations $\left(\begin{smallmatrix}1&2&3\\1&2&3\end{smallmatrix}\right)$, $\left(\begin{smallmatrix}1&2&3\\1&3&2\end{smallmatrix}\right)$, $\left(\begin{smallmatrix}1&2&3\\3&2&1\end{smallmatrix}\right)$, and $\left(\begin{smallmatrix}1&2&3\\2&1&3\end{smallmatrix}\right)$ are not.

6. *Problème des rencontres*: In the *problème des rencontres* (*matching problem*) an urn contains balls numbered 1 through n, and they are drawn out one at a time. A match occurs if ball i is the ith ball drawn. The probability that no matches occur when all the balls are drawn is $\frac{D_n}{n!}$. The problem was studied by Pierre-Rémond de Montmort (1678–1719) who studied the card game treize, in which matchings of pairs of cards were counted when two decks of cards were laid out face-up.

7. *Problème des ménages*: The *problème des ménages*, first raised by François Lucas (1842–1891), requires that n married couples be seated around a circular table so that no men are adjacent, no women are adjacent, and no husband and wife are adjacent. There are $2n!\sum_{1=0}^{n}(-1)^i(n-i)!\binom{2n-i}{i}\frac{2n}{2n-i}$ ways to seat the people. (There are $2n!$ ways to seat the n women. Regardless of how this is done, by the inclusion/exclusion principle there are $\sum_{1=0}^{n}(-1)^i(n-i)!\binom{2n-i}{i}\frac{2n}{2n-i}$ ways to seat the n men.)

8. *Determining the number D_n of derangements of* $\{1, \ldots, n\}$: Let A_i be the subset of permutations that fix object i. The permutations in the subset $A_1 \cup A_2 \cup \cdots \cup A_n$ are those that fix at least one object. Then

$$\begin{aligned}
|A_i| &= (n-1)! \quad \text{with } \tbinom{n}{1} \text{ choices for } i \\
|A_i \cap A_j| &= (n-2)! \quad \text{with } \tbinom{n}{2} \text{ choices for } i \text{ and } j \\
&\ \ \vdots \\
|A_{i_1} \cap A_{i_2} \cap \cdots \cap A_{i_k}| &= (n-k)! \quad \text{with } \tbinom{n}{k} \text{ choices for } i_1, i_2, \ldots, i_k
\end{aligned}$$

Complementation and inclusion/exclusion now yield the formula in Fact 3:

$$D_n = n! - \textstyle\sum_{k=1}^{n}(-1)^{k+1}\binom{n}{k}(n-k)! = n!\sum_{k=0}^{n}(-1)^k\frac{1}{k!}.$$

As n becomes large, $\frac{D_n}{n!}$ approaches $e^{-1} \approx 0.368$ very rapidly.

9. *Hatcheck problem*: The hatchecker at a restaurant neglects to place claim checks on n hats. Each of the n customers is given a randomly selected hat upon exiting. What is the probability that no one receives the correct hat?

There are $n!$ possible permutations of the n hats, and there are D_n cases in which no one gets the correct hat. Thus, by Example 8, the probability is approximately e^{-1}, regardless of the number of diners.

10. *Rook polynomials/arrangements of objects with restricted positions*: This describes a family of assignment or matching problems, such as matching applicants to jobs where some applicants cannot be assigned to certain jobs, the problème des ménages, and the problème des rencontres. In terms of matching n applicants to n jobs, set up an $n \times n$ "board of possibilities" where the rows are labeled by the applicants and the columns are labeled by the jobs. Square (i, j) is a *forbidden square* if applicant i cannot perform job j; the remaining squares are *allowable squares*. An allowable arrangement is an arrangement where only allowable squares are chosen, with exactly one square chosen in each row and column.

These problems can be rephrased in terms of placing rooks on a chessboard: given a chessboard with some squares forbidden, find the number of ways of placing rooks on the allowable squares of the chessboard so that no rook can capture any other rook. (In chess a rook can move any number of squares vertically or horizontally.) For a given $n \times n$ board B, let A_i be the number of ways to place n nontaking rooks on B so that the rook in row i is on a forbidden square. The total number of ways to place n nontaking rooks on allowable squares is

$$n! - |A_1 \cup \cdots \cup A_n| = n! - r_1(B)(n-1)! + r_2(B)(n-2)! - \cdots + (-1)^n r_n(B)0!$$

where the coefficients $r_i(B)$ are the number of ways to place i nontaking rooks on forbidden squares of B.

A *rook polynomial* for an $n \times n$ board B is a polynomial of the form

$$R(x,B) = r_0(B) + r_1(B)x + r_2(B)x^2 + \cdots + r_n(B)x^n,$$

where $r_0(B)$ is defined to be 1.

The numbers $r_i(B)$ can sometimes be found more easily by using a combination of the following two reduction techniques:

- $R(x,B) = R(x,B_1) \cdot R(x,B_2)$, if all forbidden squares of B appear in two disjoint sub-boards B_1 and B_2 (the sub-boards B_1 and B_2 are disjoint if the row labels of B are partitioned into two parts S_1 and S_2, the column labels of B are partitioned into two parts T_1 and T_2, and B_1 is obtained from $S_1 \times T_1$ and B_2 is obtained from $S_2 \times T_2$).
- $R(x,B) = xR(x,B_1) + R(x,B_2)$, where there is a square (i,j) of B, B_1 is obtained from B by removing all squares in row i and all squares in column j, and B_2 is obtained from B by making square (i,j) allowable.

It may be necessary to use these techniques repeatedly to obtain boards that are simple enough that the rook polynomial coefficients can be easily found.

11. Rook polynomials can be used to find the number of derangements of n objects. The forbidden squares of the board B are the squares (i,i). The first reduction technique of Example 10 used repeatedly breaks B into $B_1, \ldots, B_n$ where B_i consists only of square (i,i). Then

$$R(x,B) = R(x,B_1)R(x,B_2)\ldots R(x,B_n) = (1+x)\ldots(1+x) = (1+x)^n = \textstyle\sum_{i=0}^{n} \binom{n}{i} x^i.$$

Therefore, the number of derangements is

$$n! - \left[\binom{n}{1}(n-1)! - \binom{n}{2}(n-2)! + \cdots + (-1)^{n+1}\binom{n}{n}0!\right] = n! \textstyle\sum_{k=0}^{n} (-1)^k \frac{1}{k!}.$$

2.5 PARTITIONS

Each way to write a positive integer n as a sum of positive integers is called a partition of n. Similarly, each way to decompose a set S into a family of mutually disjoint nonempty subsets is called a partition of S. In a cyclic partition of a set, the elements of each subset are arranged into cycles, and two cyclic partitions in the same family of subsets are distinct if any of the cycle arrangements are different. The main concerns are counting the number of essentially different partitions of integers and sets, and with counting cyclic partitions of sets.

2.5.1 PARTITIONS OF INTEGERS

A positive integer can be decomposed into a sum of positive integers in various ways, taking into account restrictions on the number of parts or on the properties of the parts.

Definitions:

A ***partition*** of a positive integer n is a representation of n as the sum of positive integers. The parts are usually written in nonascending order, but order is ignored.

A ***Ferrers diagram*** or ***Young diagram*** of a partition is an array of boxes, nodes, or dots into rows of nonincreasing size so that each row represents one part of the partition (also see §2.8 on Young Tableaux).

The ***conjugate*** of a partition is the partition obtained by transposing the rows and columns of its Ferrers diagram.

Suppose we have two distinguished copies of the positive integers: one ordinary copy and one copy where each integer k is marked with an overline ($\bar{k}$). An ***overpartition*** of a positive integer n is a representation of n as a sum of positive integers in which at most one occurrence of each integer appearing as a part may be overlined.

A ***composition*** is a partition in which the order of the parts is taken into account.

A ***vector partition*** is a decomposition of an n-tuple of nonnegative integers into a sum of nonzero n-tuples of nonnegative integers, where order is ignored.

A ***vector composition*** is the same as a vector partition, except that order is taken into account.

Facts:

1. The following table gives the notation for various functions that count partitions:

function	*type of partitions counted*
$p(n)$	number of partitions of n
$Q(n)$	number of partitions of n into distinct parts
$\mathcal{O}(n)$	number of partitions of n into odd parts
$p_m(n)$	number of partitions of n with at most m parts
$q_m(n)$	number of partitions of n with no part larger than m
$p(N,M,n)$	number of partitions of n into at most M parts, with each part no larger than N
$\bar{p}(n)$	number of overpartitions of n

2. $p(m,n,n) = q_m(n)$.

3. $p(n,m,n) = p_m(n)$.

4. $p_m(n) = q_m(n)$.

5. $\mathcal{O}(n) = Q(n)$.

6. The number of compositions of n into k parts is $\binom{n-1}{n-k} = \binom{n-1}{k-1}$.

7. The number of compositions of n is 2^{n-1}.

8. The number of compositions of $n+1$ into parts greater than 1 = the number of compositions of n into odd parts = the number of compositions of $n-1$ into 1s and 2s $= F_n$, where F_n denotes the nth Fibonacci number: $F_0 = 0$, $F_1 = 1$, $F_n = F_{n-1} + F_{n-2}$ for $n \geq 2$ (§3.1.2).

9. The partition function $p(n)$ satisfies these congruences (see [Kn93] for details):

$$\begin{aligned} &p(5n+4) \equiv 0 \pmod{5} \\ &p(7n+5) \equiv 0 \pmod{7} \\ &p(11n+6) \equiv 0 \pmod{11}. \end{aligned}$$

10. The partition functions $p(n)$ and $p_m(n)$ satisfy these recurrences:

$$\begin{aligned} &p(n) - p(n-1) - p(n-2) + p(n-5) + p(n-7) + \cdots \\ &\qquad + (-1)^k p(n - \frac{k}{2}(3k-1)) + (-1)^k p(n - \frac{k}{2}(3k+1)) + \cdots = 0, \ n > 0 \\ &p_m(n) = p_m(n-m) + p_{m-1}(n). \end{aligned}$$

11. The asymptotic behavior of $p(n)$, $Q(n)$, $p_m(n)$, and $\bar{p}(n)$ is as follows (see Chapters 5 and 6 of [An98], [HaRa18], or [Kn93] for details):

$$\begin{aligned} p(n) &\sim \frac{1}{4n\sqrt{3}}\, e^{\pi\sqrt{2n/3}} \quad \text{as } n \to \infty, \\ Q(n) &\sim \frac{1}{4 \cdot 3^{1/4}}\, n^{-3/4} e^{\pi\sqrt{n/3}} \quad \text{as } n \to \infty, \\ \bar{p}(n) &\sim \frac{1}{8n} e^{\pi\sqrt{n}} \quad \text{as } n \to \infty, \\ p_m(n) &\sim \frac{n^{m-1}}{m!(m-1)!} \quad \text{as } n \to \infty, \text{ with } m \text{ fixed.} \end{aligned}$$

12. The following are generating functions (§3.2) for partition functions:

$$\begin{aligned} \sum_{n\geq 0} p(n)q^n &= \prod_{i=1}^{\infty}(1 + q^i + q^{i+i} + \cdots) = \prod_{i=1}^{\infty}\left(\sum_{m=0}^{\infty} q^{mi}\right) = \prod_{i=1}^{\infty}\frac{1}{1-q^i} \\ &= \left(\sum_{k=-\infty}^{\infty} (-1)^k q^{k(3k-1)/2}\right)^{-1} = \frac{e^{\pi i \tau/12}}{\eta(\tau)}, \end{aligned}$$

where $q = e^{2\pi i \tau}$ and $\eta(\tau)$ is the Dedekind eta function.

$$\sum_{n\geq 0} Q(n)q^n = \prod_{i=1}^{\infty}(1+q^i).$$

$$\sum_{n\geq 0} p_m(n)q^n = \prod_{i=1}^{m}(1 + q^i + q^{i+i} + \cdots) = \prod_{i=1}^{m}\left(\sum_{m=0}^{\infty} q^{mi}\right) = \prod_{i=1}^{m}\frac{1}{1-q^i}.$$

$$\sum_{n\geq 0} p(N,M,n)q^n = \prod_{j=1}^{N}\frac{(1-q^{N+M+1-j})}{1-q^j} = \frac{\prod_{j=1}^{N+M}(1-q^j)}{\prod_{j=1}^{N}(1-q^j)\prod_{j=1}^{M}(1-q^j)}.$$

$$\sum_{n\geq 0} \bar{p}(n)q^n = \prod_{i=1}^{\infty} \frac{1+q^i}{1-q^i} = \left(\sum_{k=-\infty}^{\infty} (-1)^k q^{k^2} \right)^{-1} = \frac{1}{\vartheta_4(0,q)},$$

where $\vartheta_4(z,q) = \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2niz}$ is an elliptic theta function of Jacobi; see Chapter XXI of [WhWa96].

Note: Even though these expressions for $p(N,M,n)$ look like quotients of polynomials they are actually just polynomials of degree NM. They are called *Gaussian polynomials* or *q-binomial coefficients*. (See Chapters 1 and 2 of [An98], Chapter 19 of [HaWr08], or [Ma04] for details. Also see §2.3.2.)

13. The following are additional generating functions for partition functions (see Chapter 2 of [An98] or Section 8.10 of [GaRa04] for details):

$$\begin{aligned}
\sum_{n=1}^{\infty} p(n)q^n &= 1 + \sum_{n=1}^{\infty} \frac{q^n}{(1-q)(1-q^2)\cdots(1-q^n)} \\
&= 1 + \sum_{n=1}^{\infty} \frac{q^{n^2}}{(1-q)^2(1-q^2)^2\cdots(1-q^n)^2} \\
\sum_{n=1}^{\infty} Q(n)q^n &= 1 + \sum_{n=1}^{\infty} \frac{q^{n(n+1)/2}}{(1-q)(1-q^2)\cdots(1-q^n)} \\
&= 1 + q + \sum_{n=2}^{\infty} q^n(1+q)(1+q^2)\cdots(1+q^{n-1}) \\
\sum_{n=1}^{\infty} p_m(n)q^n &= 1 + \sum_{n=1}^{\infty} \frac{(1-q^m)(1-q^{m+1})\cdots(1-q^{m+n-1})}{(1-q)(1-q^2)\cdots(1-q^n)} q^n \\
\sum_{n=1}^{\infty} \bar{p}(n)q^n &= 1 + \sum_{n=1}^{\infty} \frac{q^{n(n+1)/2}(1+1)(1+q)(1+q^2)\cdots(1+q^{n-1})}{(1-q)^2(1-q^2)^2\cdots(1-q^n)^2}.
\end{aligned}$$

14. See [GrKnPa94] for an algorithm for generating partitions.

15. The following table gives some values of $p_m(n)$. More extensive tables appear in [GuGwMi58]:

$n\backslash m$	0	1	2	3	4	5	6	7	8	9	10
0	1	1	1	1	1	1	1	1	1	1	1
1	0	1	1	1	1	1	1	1	1	1	1
2	0	1	2	2	2	2	2	2	2	2	2
3	0	1	2	3	3	3	3	3	3	3	3
4	0	1	3	4	5	5	5	5	5	5	5
5	0	1	3	5	6	7	7	7	7	7	7
6	0	1	4	7	9	10	11	11	11	11	11
7	0	1	4	8	11	13	14	15	15	15	15
8	0	1	5	10	15	18	20	21	22	22	22
9	0	1	5	12	18	23	26	28	29	30	30
10	0	1	6	14	23	30	35	38	40	41	42

16. The following table gives values for $p(n)$ and $Q(n)$:

n	$p(n)$	$Q(n)$	n	$p(n)$	$Q(n)$	n	$p(n)$	$Q(n)$
0	1	1	17	297	38	34	12,310	512
1	1	1	18	385	46	35	14,883	585
2	2	1	19	490	54	36	17,977	668
3	3	2	20	627	64	37	21,637	760
4	5	2	21	792	76	38	26,015	864
5	7	3	22	1,002	89	39	31,185	982
6	11	4	23	1,255	104	40	37,338	1,113
7	15	5	24	1,575	122	41	44,583	1,260

9	30	8	26	2,436	165	43	63,261	1,610
10	42	10	27	3,010	192	44	75,175	1,816
11	56	12	28	3,718	222	45	89,134	2,048
12	77	15	29	4,565	256	46	105,558	2,304
13	101	18	30	5,604	296	47	124,754	2,590
14	135	22	31	6,842	340	48	147,273	2,910
15	176	27	32	8,349	390	49	173,525	3,264
16	231	32	33	10,143	448	50	204,226	3,658

Examples:

1. The number 4 has five partitions:

$$4 \quad 3+1 \quad 2+2 \quad 2+1+1 \quad 1+1+1+1.$$

2. The number 4 has eight compositions:

$$4 \quad 1+3 \quad 3+1 \quad 2+2 \quad 2+1+1 \quad 1+2+1 \quad 1+1+2 \quad 1+1+1+1.$$

3. The number 4 has fourteen overpartitions:

$$4 \quad \bar{4} \quad 3+1 \quad \bar{3}+1 \quad 3+\bar{1} \quad \bar{3}+\bar{1} \quad 2+2 \quad 2+\bar{2} \quad 2+1+1 \quad \bar{2}+1+1 \quad 2+1+\bar{1} \quad \bar{2}+1+\bar{1}$$

$$1+1+1+1 \quad 1+1+1+\bar{1}$$

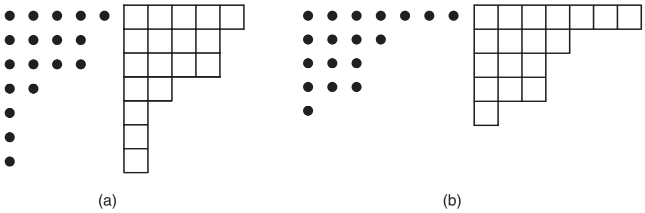
4. The four vector partitions of $(2, 1)$ are

$$(2,1) \quad (2,0)+(0,1) \quad (1,0)+(1,0)+(0,1) \quad (1,0)+(1,1)$$

5. The partition $5+4+4+2+1+1+1$ of 18 has the Ferrers diagram in part (a) of the following figure. Its conjugate is the partition $7+4+3+3+1$, with the Ferrers diagram in part (b) of the figure.

6. *Identical balls into identical bins*: The number of ways that n identical balls can be placed into k identical bins, with any number of balls allowed in each bin, is given by $p_k(n)$.

7. *Identical balls into identical bins with no bin allowed to be empty*: The number of ways that n identical balls can be placed into k identical bins ($n \geq k$), with any number of balls allowed in each bin and no bin allowed to remain empty, is given by $p_k(n) - p_{k-1}(n)$.



8. *Making change:* Imagine an unlimited supply of silver coins in all possible unit denominations $1, 2, 3, 4, \ldots$, and exactly one gold coin for each unit denomination $1, 2, 3, 4, \ldots$. Within a given denomination, the coins are only distinguishable by metal content. The number of ways to "make change" for n units using only the silver coins is $p(n)$, while the number of ways to make change for n units using the available silver *and* gold coins is $\bar{p}(n)$.

2.5.2 STIRLING COEFFICIENTS

Definitions:

A ***cyclic partition*** of a set is a partition of the set (into disjoint subsets whose union is the entire set) where the elements of each subset are arranged into cycles. Two cyclic partitions using the same family of subsets are distinct if any of the cycle arrangements are different.

The ***Stirling cycle number*** $\left[{n \atop k}\right]$ is the number of ways to partition n objects into k nonempty cycles.

The ***Stirling number of the first kind*** $s(n, k)$ is the coefficient of x^k in the polynomial $x(x-1)(x-2)\ldots(x-n+1)$. Thus,

$$\sum_{k=0}^{n} s(n,k)x^k = x(x-1)(x-2)\ldots(x-n+1).$$

The ***Stirling subset number*** $\left\{{n \atop k}\right\}$ is the number of ways to partition a set of n objects into k nonempty subsets.

The ***Stirling numbers of the second kind*** $S(n, k)$ are defined implicitly by the equation

$$x^n = \sum_{k=0}^{n} S(n,k)x(x-1)(x-2)\ldots(x-k+1).$$

The ***Bell number*** B_n (§3.1.8) is the number of partitions of a set of n objects. (Eric Temple Bell, 1883–1960)

Facts:

1. $s(n,k)(-1)^{n-k} = \left[{n \atop k}\right]$.

2. $S(n,k) = \left\{{n \atop k}\right\}$.

3. The following table gives Stirling numbers of the first kind, $s(n,k)$:

$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10
0	1										
1	0	1									
2	0	−1	1								
3	0	2	−3	1							
4	0	−6	11	−6	1						
5	0	24	−50	35	−10	1					
6	0	−120	274	−225	85	−15	1				
7	0	720	−1,764	1,624	−735	175	−21	1			
8	0	−5,040	13,068	−13,132	6,769	−1,960	322	−28	1		
9	0	40,320	−109,584	118,124	−67,284	22,449	−4,536	546	−36	1	
10	0	−362,880	1,026,576	−1,172,700	723,680	−269,325	63,273	−9,450	870	−45	1

4. The following table gives Stirling subset numbers of the second kind, $S(n,k) = \left\{ {n \atop k} \right\}$:

$n\backslash k$	0	1	2	3	4	5	6	7	8	9	10
0	1										
1	0	1									
2	0	1	1								
3	0	1	3	1							
4	0	1	7	6	1						
5	0	1	15	25	10	1					
6	0	1	31	90	65	15	1				
7	0	1	63	301	350	140	21	1			
8	0	1	127	966	1,701	1,050	266	28	1		
9	0	1	255	3,035	7,770	6,951	2,646	462	36	1	
10	0	1	511	9,330	34,501	42,525	22,827	5,880	750	45	1

5. $B_n = \sum_{k=1}^{n} \left\{ {n \atop k} \right\}$.

6. The first fifteen Bell numbers are:

$B_1 = 1$	$B_2 = 2$	$B_3 = 5$	$B_4 = 15$
$B_5 = 52$	$B_6 = 203$	$B_7 = 877$	$B_8 = 4{,}140$
$B_9 = 21{,}147$	$B_{10} = 115{,}975$	$B_{11} = 678{,}570$	$B_{12} = 4{,}213{,}597$
$B_{13} = 27{,}644{,}437$	$B_{14} = 190{,}899{,}322$	$B_{15} = 1{,}382{,}958{,}545.$	

7. The following table lists some identities involving Stirling numbers:

$\left[{n \atop k}\right] = (n-1)\left[{n-1 \atop k}\right] + \left[{n-1 \atop k-1}\right],\ (k>0)$ $\left[{n \atop 0}\right] = \begin{cases} 0, & \text{if } n \neq 0 \\ 1, & \text{if } n = 0 \end{cases}$	*cycle number recursion*
$\left\{{n \atop k}\right\} = k\left\{{n-1 \atop k}\right\} + \left\{{n-1 \atop k-1}\right\},\ (k>0)$ $\left\{{n \atop 0}\right\} = \begin{cases} 0, & \text{if } n \neq 0 \\ 1, & \text{if } n = 0 \end{cases}$	*subset number recursion*
$\sum_k \left[{n \atop k}\right]\left\{{k \atop m}\right\}(-1)^{n-k} = \begin{cases} 0, & \text{if } n \neq m \\ 1, & \text{if } n = m \end{cases}$ $\sum_k \left\{{n \atop k}\right\}\left[{k \atop m}\right](-1)^{n-k} = \begin{cases} 0, & \text{if } n \neq m \\ 1, & \text{if } n = m \end{cases}$	*inversion formulas*
$\left\{{n \atop 1}\right\} = \left\{{n \atop n}\right\} = 1$	
$\left\{{n \atop 2}\right\} = 2^{n-1} - 1$	
$\left\{{n \atop k}\right\}k! =$ the number of onto functions from an n-set to a k-set	
$\sum_{k=0}^{n} \left[{n \atop k}\right] = n!$	
$\sum_{n=0}^{\infty} S(n+k,k)x^n = \dfrac{1}{(1-x)(1-2x)\dots(1-kx)}$	
$\sum_{n=0}^{\infty} \dfrac{s(n,k)x^n}{n!} = \dfrac{(\log(1+x))^k}{k!}$	
$\sum_{n=0}^{\infty} \dfrac{S(n,k)x^n}{n!} = \dfrac{1}{k!}(e^x-1)^k$	

8. The following give combinatorial interpretations of some of the identities involving Stirling numbers:

- *Stirling cycle number recursion*: When partitioning n objects into k cycles, there are $\left[{n-1 \atop k-1}\right]$ ways in which the last object has a cycle to itself. Otherwise, there are $\left[{n-1 \atop k}\right]$ ways to partition the other $n-1$ objects into k cycles, and then $n-1$ choices of a location into which the last object can be inserted.

- *Stirling subset number recursion*: When partitioning n objects into k nonempty subsets, there are $\left\{{n-1 \atop k-1}\right\}$ ways in which the last object has a subset to itself. Otherwise, there are $\left\{{n-1 \atop k}\right\}$ ways to partition the other $n-1$ objects into k subsets, and then k choices of a subset into which the last object can be inserted.

- $\sum_{k=0}^{n} \left[{n \atop k}\right] = n!$: The partitions into cycles are in a one-to-one correspondence with the permutations of n objects, since each permutation can be represented as a composition of disjoint cycles.

- $\left[{n \atop k}\right]$ is the number of ways to seat n individuals around k identical circular tables so that no table is empty.

- $H_n = \frac{1}{n!}\left[{n+1 \atop 2}\right]$, where H_n is the nth Harmonic number (§3.1.7).

Examples:

1. $x(x-1)(x-2)(x-3) = x^4-6x^3+11x^2-6x$, and hence there are $\left[{4 \atop 2}\right] = 11$ permutations of $\{1,2,3,4\}$ with 2 cycles: (12)(34), (13)(24), (14)(23), (1)(234), (1)(324), (2)(134), (2)(314), (3)(124), (3)(214), (4)(123), (4)(213). Also, $s(4,2) = (-1)^{4-2} \cdot 11$.

2. $H_3 = 1 + \frac{1}{2} + \frac{1}{3} = \frac{11}{6}$. As seen in Example 1, $\left[{4 \atop 2}\right] = 11$. So we have $H_3 = \frac{1}{3!}\left[{4 \atop 2}\right]$.

3. $x^4 = x(x-1)(x-2)(x-3)+6x(x-1)(x-2)+7x(x-1)+x$, and hence there are exactly $\left\{{4 \atop 2}\right\} = 7$ set-partitions of $\{1,2,3,4\}$ into two blocks: $\{1\}$ & $\{2,3,4\}$, $\{2\}$ & $\{1,3,4\}$, $\{3\}$ & $\{1,2,4\}$, $\{4\}$ & $\{1,2,3\}$, $\{1,2\}$ & $\{3,4\}$, $\{1,3\}$ & $\{2,4\}$, $\{1,4\}$ & $\{2,3\}$.

2.6 BURNSIDE/PÓLYA COUNTING FORMULA

Burnside's lemma and Pólya's formula are used to count the number of "really different" configurations, such as tic-tac-toe patterns and placement of beads on a bracelet, in which various symmetries play a role. One of the scientific applications of Pólya's formula is the enumeration of isomers of a chemical compound. From a mathematical perspective, Burnside/Pólya methods count orbits under a permutation group action. (See §5.3.1.)

2.6.1 PERMUTATION GROUPS AND CYCLE INDEX POLYNOMIALS

Definitions:

A ***permutation on a set*** S is a one-to-one mapping of S onto itself. In this context, the elements of S are called ***objects***.

A permutation π of a finite set S is ***cyclic*** if there is a subcollection of objects that can be arranged in a cycle $(a_1a_2\ldots a_n)$ so that each object a_j is mapped by π onto the next object in the cycle and every object of S not in this cycle is fixed by π, that is, mapped to itself.

The ***tabular form*** of a permutation π on a finite set S is a matrix with two rows. In the first row, each object from S is listed once. Below the object a is its image $\pi(a)$, in this form:

$$\begin{pmatrix} a_1 & a_2 & \cdots & a_n \\ \pi(a_1) & \pi(a_2) & \cdots & \pi(a_n) \end{pmatrix}$$

The ***cycle decomposition*** (***form***) of a permutation π is a concatenation of cyclic permutations whose object subcollections are disjoint and whose product is π. (Sometimes the 1-cycles are explicitly written and sometimes they are omitted.)

A set P of permutations of a set S is ***closed under composition*** if the composition of each pair of permutations in P is also in P.

A set P of permutations of a set S is ***closed under inversion*** if for every permutation $\pi \in P$, $\pi^{-1} \in P$.

A ***permutation group*** $\mathcal{G} = (P, S)$ is a nonempty set P of permutations on a set S such that P is closed under composition and inversion.

The ***cycle structure*** of a permutation π is an expression (multivariate polynomial) of the form $x_1^{m_1}x_2^{m_2}\ldots x_k^{m_k}$, where m_j is the number of cycles of size j in the cyclic decomposition of π.

The ***cycle index*** of a permutation group $\mathcal{G}$ is the multivariate polynomial that is the sum of the cycle structures of all the permutations in $\mathcal{G}$, divided by the number of permutations in $\mathcal{G}$. The cycle index polynomial is written $P_{\mathcal{G}}(x_1, x_2, \ldots, x_n)$. (The notation $P_{\mathcal{G}}$ honors George Pólya (1887–1985) who greatly advanced the application of the cycle index polynomial to counting.)

Facts:

1. Every permutation has a tabular form.

2. The tabular form of a permutation is unique up to the order in which the objects of the permuted set are listed in the first row.

3. Every permutation has a cycle decomposition.

4. The cycle decomposition of a permutation into a product of disjoint cyclic permutations is unique up to the order of the factors.

5. The collection of all permutations on a set S forms a permutation group.

Examples:

1. The permutation $\binom{a\ b\ c\ d}{c\ d\ a\ b}$ has the cycle decomposition $(ac)(bd)$.

2. The symmetric group Σ_3 of all 6 possible permutations on $\{a, b, c\}$ has the following elements:

$$(a)(b)(c),\ (ab)(c),\ (ac)(b),\ (a)(bc),\ (abc),\ (acb)$$

with respective cycle structures

$$x_1^3,\ x_1x_2,\ x_1x_2,\ x_1x_2,\ x_3,\ x_3.$$

Thus, the cycle index polynomial is

$$P_{\Sigma_3} = \tfrac{1}{6}\big(x_1^3 + 3x_1x_2 + 2x_3\big).$$

3. The group Σ_4 of all 24 permutations on $\{a, b, c, d\}$ has the following elements:

$$\begin{array}{llllll}
(a)(b)(c)(d) & (ab)(c)(d) & (ac)(b)(d) & (ad)(b)(c) & (a)(bc)(d) & (a)(bd)(c) \\
(a)(b)(cd) & (abc)(d) & (acb)(d) & (abd)(c) & (adb)(c) & (acd)(b) \\
(adc)(b) & (a)(bcd) & (a)(bdc) & (ab)(cd) & (ac)(bd) & (ad)(bc) \\
(abcd) & (abdc) & (acbd) & (acdb) & (adbc) & (adcb)
\end{array}$$

The cycle index polynomial is

$$P_{\Sigma_4} = \tfrac{1}{24}\left[x_1^4 + 6x_1^2x_2 + 8x_1x_3 + 3x_2^2 + 6x_4\right].$$

2.6.2 ORBITS AND SYMMETRIES

Definitions:

Given a permutation group $\mathcal{G} = (P, S)$, the ***orbit*** of $a \in S$ is the set $\{\, \pi(a) \mid \pi \in P \,\}$.

A ***symmetry of a figure*** (or ***symmetry motion***) is a spatial motion of the figure onto itself.

Facts:

1. Given a permutation group $\mathcal{G} = (P, S)$, the relation R defined by

$$aRb \iff \text{there exists } \pi \in P \text{ such that } \pi(a) = b$$

is an equivalence relation (§1.4.2), and the equivalence classes under it are precisely the orbits.

2. The set of all symmetries on a figure forms a group.

3. The set of symmetries on a polygon induces a permutation group action on its corner set and a permutation group action on its edge set.

Examples:

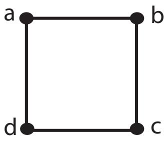
1. Acting on the set $\{a, b, c, d, e\}$ is the following permutation group:

$$(a)(b)(c)(d)(e), (ab)(c)(d)(e), (a)(b)(cd)(e), \text{ and } (ab)(cd)(e).$$

The orbits of this group are $\{a, b\}, \{c, d\}, \{e\}$. The cycle index is

$$\tfrac{1}{4}\left[x_1^5 + 2x_1^3x_2 + x_1x_2^2\right].$$

2. A square with corners a, b, c, d (in clockwise order) has eight possible symmetries: four rotations in the plane around the center of the square and four reflections (which could also be achieved by 180° spatial rotations out of the plane). See the following figure.

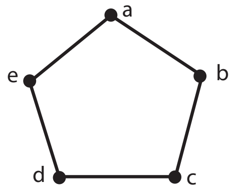


rotations		*reflections*	
0°	(a)(b)(c)(d)	horizontal axis	(a d)(b c)
90°	(a b c d)	vertical axis	(a b)(c d)
180°	(a c)(b d)	down-diagonal axis	(a)(c)(b d)
270°	(a d c b)	up-diagonal axis	(b)(d)(a c)

There is only one orbit, $\{a, b, c, d\}$, and the cycle index for the group of symmetries of a square acting on its corner set (the dihedral group D_4) is

$$P_{D_4} = \tfrac{1}{8}\left[x_1^4 + 2x_4 + 3x_2^2 + 2x_1^2x_2\right].$$

3. A pentagon has ten different symmetries. Five are rotations in the plane around the center of the pentagon: $0° = (a)(b)(c)(d)(e), 72° = (abcde), 144° = (acebd), 216° = (adbec)$, and $288° = (aedcb)$; five are reflections (or equivalently, spatial rotations of 180° out of the plane) around axis lines through a corner and the middle of an opposite side: $(a)(be)(cd), (b)(ac)(de), (c)(ae)(bd), (d)(ab(ce)$, and $(e)(ad)(bc)$. See the following figure. There is only one orbit, $\{a, b, c, d, e\}$, and the associated cycle index is $\frac{1}{10}\left[x_1^5 + 4x_5 + 5x_1x_2^2\right]$.



2.6.3 COLOR PATTERNS AND INDUCED PERMUTATIONS

Definitions:

A ***coloring*** of a set S from a set of n colors is a function from S to the set $\{1, \ldots, n\}$, whose elements are regarded as "colors". The set of all such colorings is denoted $C(S, n)$.

A ***corner coloring*** of a (polygonal or polyhedral) geometric figure is a coloring of its set of corners.

An ***edge coloring*** of a geometric figure is a coloring of its set of edges.

Let c_1 and c_2 be colorings of the set S and let π be a permutation of S. Write $\pi(c_1) = c_2$ if $c_1(a) = c_2(\pi(a))$ for every $a \in S$. The correspondence $c_1 \mapsto c_1 \circ \pi^{-1}$ is the ***map induced by π on the colorings of S***. (The composition $c_1 \circ \pi^{-1}$ assigns a color to every object $a \in S$, namely the color $c_1(\pi^{-1}(a))$.

Two corner colorings of a figure are ***equivalent*** if one can be mapped to the other by a symmetry. Similar definitions apply to edge colorings and to face colorings.

Two colorings c_1 and c_2 of a set S are ***equivalent under a group*** $\mathcal{G} = (P, S)$ if there is a permutation $\pi \in P$ such that $\pi(c_1) = c_2$.

A ***corner coloring pattern of a figure with respect to a set of symmetries*** is a set of mutually equivalent colorings of the figure.

Facts:

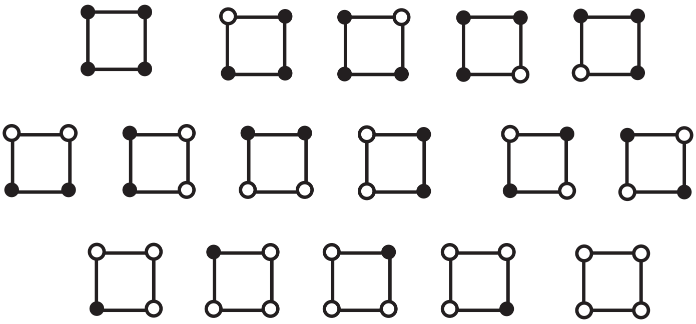
1. Let $\mathcal{G} = (P, S)$ be a permutation group. Then the induced action of P on the set $C(S, n)$ of colorings with n colors is a permutation group action.

2. When P acts on the set $C(S, n)$ of colorings of S, the numbers of permuted objects and orbits, and the cycle index polynomial, are different from when P acts on S itself.

3. In permuting the set S of corners of a figure, a symmetry of a figure simultaneously induces a permutation of the set of all its corner colorings. An analogous fact holds for edge colorings.

Examples:

1. In Example 2 of §2.6.2, a permutation group of eight elements acts on the four corners of a square. There is only one orbit, and the cycle index is $\frac{1}{8}\left[x_1^4 + 2x_4 + 3x_2^2 + 2x_1^2x_2\right]$. The following figure shows what happens when the same group acts on the set of black-white colorings. The permuted set has 16 colorings, there are six orbits, and the cycle index polynomial is $\frac{1}{8}\left[x_1^{16} + 2x_1^2x_2x_4^3 + 3x_1^4x_2^6 + 2x_1^8x_2^4\right]$.



2.6.4 FIXED POINTS AND BURNSIDE'S LEMMA

Definition:

An element $a \in S$ is a ***fixed point*** of the permutation π if $\pi(a) = a$. The set of all fixed points of π is denoted *fix*(π).

Facts:

1. The number of fixed points of a permutation π equals the number of 1-cycles in its cycle decomposition.

2. *Burnside's lemma*: Let $\mathcal{G}$ be a group of permutations acting on a set S. Then the number of orbits induced on S is given by

$$\frac{1}{|\mathcal{G}|}\sum_{\pi \in \mathcal{G}} |\mathit{fix}(\pi)|.$$

Note: The theorem commonly called "Burnside's lemma" originated with Georg Frobenius (1848–1917). A widely available book by William Burnside (1852–1927) published in 1911 stated and proved the same result, without mentioning its prior discovery.

3. Evaluation of the sum in Burnside's lemma is simplified by using the cycle index polynomial and Fact 1. For each term in the polynomial, multiply the coefficient by the exponent of x_1, and then sum these products.

4. *Special Burnside's lemma (for colorings)*: Let $\mathcal{G}$ be a group of permutations acting on a set S. Then the number of orbits induced on $C(S, n)$ (the set of colorings of S from a set of n colors) is given by substituting n for each variable in the cycle index polynomial.

5. The following table gives information on the number of corner coloring patterns of selected figures.

figure	*colors*			
	2	3	4	m
triangle	4	11	20	$\frac{1}{6}[m^3 + 3m^2 + 2m]$
square	6	21	55	$\frac{1}{8}[m^4 + 2m^3 + 3m^2 + 2m]$
pentagon	8	39	136	$\frac{1}{10}[m^5 + 5m^3 + 4m]$
hexagon	13	92	430	$\frac{1}{12}[m^6 + 3m^4 + 4m^3 + 2m^2 + 2m]$
heptagon	18	198	1,300	$\frac{1}{14}[m^7 + 7m^4 + 6m]$
octagon	30	498	4,183	$\frac{1}{16}[m^8 + 4m^5 + 5m^4 + 2m^2 + 4m]$
nonagon	46	1,219	15,084	$\frac{1}{18}[m^9 + 9m^5 + 2m^3 + 6m]$
decagon	78	3,210	53,764	$\frac{1}{20}[m^{10} + 5m^6 + 6m^5 + 4m^2 + 4m]$
tetrahedron	5	15	36	$\frac{1}{12}[m^4 + 11m^2]$
cube	23	333	2914	$\frac{1}{24}[m^8 + 17m^4 + 6m^2]$

Examples:

1. In Example 1 of §2.6.2, the permutation group is

$$\{(a)(b)(c)(d)(e),\ (ab)(c)(d)(e),\ (a)(b)(cd)(e),\ (ab)(cd)(e)\}.$$

The cycle index is $\frac{1}{4}\left[x_1^5 + 2x_1^3x_2 + x_1x_2^2\right]$. By Burnside's lemma and Fact 3 there are $\frac{1}{4}\left[1 \cdot 5 + 2 \cdot 3 + 1 \cdot 1\right] = \frac{12}{4} = 3$ orbits. The orbits are $\{a, b\}, \{c, d\}, \{e\}$.

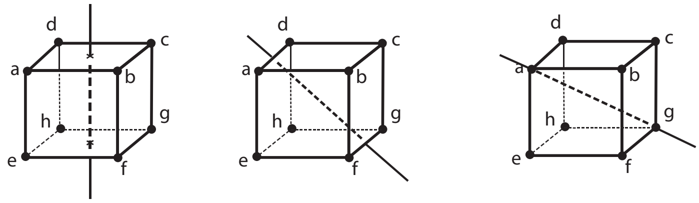
2. Example 1 of §2.6.3 shows 16 colorings of the corners of the square with colors black or white. There are six orbits, and the cycle index for the action on the colorings is $\frac{1}{8}\left[x_1^{16} + 2x_1^2x_2x_4^3 + 3x_1^4x_2^6 + 2x_1^8x_2^4\right]$. By Burnside's lemma and Fact 3, there are $\frac{1}{8}[1 \cdot 16 + 2 \cdot 2 + 3 \cdot 4 + 2 \cdot 8] = \frac{48}{8} = 6$ orbits.

It is simpler to apply the Special Burnside's lemma to the cycle index for the action on the square (from Example 2 of §2.6.2), $\frac{1}{8}\left[x_1^4 + 2x_4 + 3x_2^2 + 2x_1^2x_2\right]$, which yields $\frac{1}{8}\left[1 \cdot 2^4 + 2 \cdot 2 + 3 \cdot 2^2 + 2 \cdot 2^2 \cdot 2\right] = 6$ orbits.

3. (*Continuing Example 3 of §2.6.2*): The cycle index of the group of symmetries of the pentagon is $\frac{1}{10}\left[x_1^5 + 4x_5 + 5x_1x_2^2\right]$. By the Special Burnside's lemma, the number of m-colorings of the corners of an unoriented pentagon is $\frac{1}{10}\left[m^5 + 4m + 5m^3\right]$. For $m = 3$, the formula gives $\frac{1}{10}(243 + 12 + 135) = 39$ 3-coloring patterns of a pentagon.

4. A cube has 24 rotational symmetries, which act on the corners. The identity symmetry has cycle structure x_1^8. There are three additional classes of symmetries, as follows:

(a) Rotations of $90°, 180°$, or $270°$ about an axis line through the middles of opposite faces, for example, through $abcd$ and $efgh$ in part (a) of the following figure. A 90° rotation, such as $(abcd)(efgh)$, has cycle structure x_4^2. All 270° rotations have that same structure. A 180° rotation, such as $(ac)(bd)(eg)(fh)$, has cycle structure x_2^4. There are three pairs of opposite faces, and so the total contribution to the cycle index of opposite-face rotations is $6x_4^2 + 3x_2^4$.



(a) rotation about opposite faces

(b) rotation about opposite edges

(c) rotation about opposite corners

(b) Rotating 180° about an axis line through the middles of opposite edges, for example, through edges ad and fg in part (b) of the figure. This rotation, $(ad)(bh)(ce)(fg)$, has cycle structure x_2^4. There are six pairs of opposite edges, and so the total contribution of opposite-edge rotations is $6x_2^4$.

(c) Rotating 120° or 240° about an axis line through opposite corners, for example, about the line through corners a and g in part (c) of the figure. Any 120° rotation, such as $(a)(bde)(chf)(g)$, has cycle structure $x_1^2x_3^2$. A 240° rotation has the same structure. There are four pairs of opposite corners, and so the contribution of opposite-corner rotations is $8x_1^2x_3^2$.

Collect terms to obtain the cycle index $\frac{1}{24}\left[x_1^8 + 6x_4^2 + 9x_2^4 + 8x_1^2x_3^2\right]$. Thus, the number of m-colorings of the corners of an unoriented cube is $\frac{1}{24}\left[m^8 + 6m^2 + 9m^4 + 8m^4\right]$. For $m = 2$ and 3, the formula gives 23 2-coloring patterns and 333 3-coloring patterns.

2.6.5 PÓLYA'S ENUMERATION FORMULA

Definition:

A ***pattern inventory*** is a generating function (§3.2) that enumerates the numbers of coloring patterns of a given figure.

Facts:

1. *Pólya's enumeration formula*: Let $\mathcal{G} = (P, S)$ be a permutation group and let $\{c_1, \ldots, c_n\}$ be a set of names for n colors for the objects of S. Then the pattern inventory with respect to $\mathcal{G}$ for the set of all n-colorings of S is given by substituting $(c_1^j + \cdots + c_n^j)$ for x_j in the cycle index $P_{\mathcal{G}}(x_1, \ldots, x_m)$.

Note: This theorem was published in 1937. Essentially the same result was derived by H. Redfield in 1927.

2. Pólya's enumeration formula has many applications in enumerating various families of graphs. This approach was pioneered by F. Harary [HaPa73].

3. Pólya's enumeration formula has many applications in which some practical question is modeled as a graph coloring problem.

Examples:

1. The pattern inventory of black-white colorings of the corners of a triangle is

$$1b^3 + 1b^2w + 1bw^2 + 1w^3.$$

This means there is one coloring pattern with all three corners black, one with two black corners and one white corner, etc.

2. (*Continuing Example* 2 *of* §*2.6.4*): For corner colorings of the square, the cycle index is

$$P_{D_4}(x_1, x_2, x_3, x_4) = \tfrac{1}{8}\left[x_1^4 + 2x_1^2x_2 + 3x_2^2 + 2x_4\right].$$

By Pólya's enumeration formula, the pattern inventory for black-white colorings of the corners of the square is

$$\begin{aligned}&P_{D_4}[(b+w), (b^2+w^2), (b^3+w^3), (b^4+w^4)]\\ &\quad= \tfrac{1}{8}\left[(b+w)^4 + 2(b+w)^2(b^2+w^2) + 3(b^2+w^2)^2 + 2(b^4+w^4)\right]\\ &\quad= \tfrac{1}{8}\left[8b^4 + 8b^3w + 16b^2w^2 + 8bw^3 + 8w^4\right] = 1b^4 + 1b^3w + 2b^2w^2 + 1bw^3 + 1w^4.\end{aligned}$$

This pattern inventory may be confirmed by examining the drawing in Example 1 of §2.6.3.

3. (*Continuing Example 3 of* §*2.6.4*): For corner colorings of the pentagon, the cycle index is

$$P_{D_5}(x_1, x_2, \ldots, x_5) = \tfrac{1}{10}\left[x_1^5 + 4x_5 + 5x_1x_2^2\right].$$

By Pólya's enumeration formula, the pattern inventory for black-white colorings of the corners of the pentagon (confirmable by drawing pictures) is

$$\begin{aligned}&P_{D_5}((b+w), (b^2+w^2), (b^3+w^3), (b^4+w^4), (b^5+w^5))\\ &\quad= \tfrac{1}{10}\left[(b+w)^5 + 4(b^5+w^5) + 5(b+w)(b^2+w^2)^2\right]\\ &\quad= \tfrac{1}{10}\left[10b^5 + 10b^4w + 20b^3w^2 + 20b^2w^3 + 10bw^4 + 10w^5\right]\\ &\quad= 1b^5 + 1b^4w + 2b^3w^2 + 2b^2w^3 + 1bw^4 + 1w^5.\end{aligned}$$

4. (*Continuing Example 4 of* §*2.6.4*): For corner colorings of the cube, the cycle index is

$$P_{\mathcal{G}}(x_1, \ldots, x_4) = \tfrac{1}{24}\left[x_1^8 + 6x_4^2 + 9x_2^4 + 8x_1^2x_3^2\right].$$

By Pólya's enumeration formula, the pattern inventory for black-white colorings of the corners of the cube is

$$\begin{aligned}
&P_{\mathcal{G}}\left((b+w),(b^2+w^2),(b^3+w^3),(b^4+w^4)\right)\\
&\quad=\tfrac{1}{24}\left[(b+w)^8+6(b^4+w^4)^2+9(b^2+w^2)^4+8(b+w)^2(b^3+w^3)^2\right]\\
&\quad=b^8+b^7w+3b^6w^2+3b^5w^3+7b^4w^4+3b^3w^5+3b^2w^6+bw^7+w^8.
\end{aligned}$$

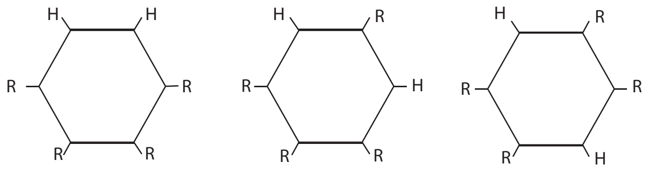
5. *Organic chemistry*: Two structurally different compounds with the same chemical formula are called *isomers*. For instance, to two of the six carbons (C) in a ring there might be attached a hydrogen (H), and to each of the four other carbons some other radical (R), thereby yielding the chemical formula $C_6H_2R_4$. The number of different isomers (structurally different arrangements of the radicals) is the same as the number of coloring patterns of a hexagon when two of the corners are "colored" H and four "colored" R. The cycle index for the symmetries of a hexagon, in terms of corner permutations, is

$$P_{D_6}(x_1,\ldots,x_6)=\tfrac{1}{12}\left[x_1^6+2x_6+2x_3^2+4x_2^3+3x_1^2x_2^2\right].$$

Substituting (H^j+R^j) for x^j yields a pattern inventory listing the number of isomers of $C_6H_iR_{6-i}$:

$$\begin{aligned}
&\tfrac{1}{12}\left[(H+R)^6+2(H^6+R^6)+2(H^3+R^3)^2+4(H^2+R^2)^3+3(H+R)^2(H^2+R^2)^2\right]\\
&\quad=\tfrac{1}{12}\left[12H^8+12H^5R+36H^4R^2+36H^3R^3+36H^2R^4+12HR^5+12R^6\right]\\
&\quad=1H^8+1H^5R+3H^4R^2+3H^3R^3+3H^2R^4+1HR^5+1R^6.
\end{aligned}$$

The three possible coloring patterns corresponding to $3H^2R^4$ are shown in the following figure:



2.7 MÖBIUS INVERSION COUNTING

Möbius inversion is an important tool used to solve a variety of counting problems such as counting how many numbers are relatively prime to some given number (without individually checking each smaller number) and counting certain types of circular arrangements. It generalizes the principle of inclusion/exclusion. (Augustus Ferdinand Möbius, 1790–1868)

2.7.1 MÖBIUS INVERSION

Definitions:

The ***Kronecker delta function*** $\delta(x, y)$ is defined by the rule

$$\delta(x, y) = \begin{cases} 1 & \text{if } x = y \\ 0 & \text{otherwise.} \end{cases}$$

The ***Möbius function*** is the function μ from the set of positive integers to the set of integers where

$$\mu(m) = \begin{cases} 1 & \text{if } m = 1 \\ (-1)^k & \text{if } m = p_1 p_2 \dots p_k \text{ (the product of } k \text{ distinct primes)} \\ 0 & \text{if } m \text{ is divisible by the square of a prime.} \end{cases}$$

Note: See Chapter 11 for Möbius functions defined on partially ordered sets.

For a positive integer n, the ***Euler phi-function*** $\phi(n)$ is the number of positive integers less than n that are relatively prime to n.

Facts:

1. For the Möbius function μ defined on the set of positive integers:

- μ is *multiplicative*: if $\gcd(m, n) = 1$, then $\mu(mn) = \mu(m)\mu(n)$;
- μ is not *completely multiplicative*: $\mu(mn) = \mu(m)\mu(n)$ is not always true;
- $\sum\limits_{d|n} \mu(d)$, where the sum is taken over all positive divisors of n, is 1 if $n = 1$ and 0 if $n > 1$.

2. *Möbius inversion formula*: If $f(n)$ and $g(n)$ are defined for all positive integers and $f(n) = \sum\limits_{d|n} g(d)$, then

$$g(n) = \sum_{d|n} \mu(d) f(n/d).$$

3. For every positive integer n, $n = \sum\limits_{d|n} \phi(d)$.

Examples:

1. Applying the Möbius inversion formula to the expression given in Fact 3 produces

$$\phi(n) = \sum_{d|n} \mu(d) \frac{n}{d}.$$

As an illustration, $\phi(12) = \sum\limits_{d|12} \mu(d) \frac{12}{d} = [\mu(1) \cdot 12 + \mu(2) \cdot 6 + \mu(3) \cdot 4 + \mu(4) \cdot 3 + \mu(6) \cdot 2 + \mu(12) \cdot 1] = 12 - 6 - 4 + 0 + 2 + 0 = 4$.

2. *Circular permutations with repetitions*: Given an alphabet of m letters, how many circular permutations of length n are possible, if repeated letters are allowed and two permutations are the same if the second can be obtained from the first by rotation? The problem was first solved by Percy A. MacMahon in 1892.

A circular permutation of length n has a period d, where $d|n$. (The *period* of a circular permutation, viewed as a circular string, is the length of the shortest substring that repeats end-to-end to give the entire string.) Let $g(d)$ be the number of length d circular permutations that have period d. A circular permutation of length n can be constructed from one of length d (where $d|n$) by concatenating it with itself $\frac{n}{d}$ times. For example, the circular permutation *aabbaabb* (where beginning and end are joined) of period four can be obtained by taking the circular permutation *aabb* and opening it up at one of four spots between the letters, to obtain any of four linear strings *aabb*, *abba*, *bbaa*, and *baab*. Join one of these to itself, obtaining *aabbaabb*, *abbaabba*, *bbaabbaa*, and *baabbaab*, and then join the beginning and the end to form the circular permutation *aabbaabb*.

For any positive integer k, there are $dg(d)$ linear strings of length k obtained by taking $\frac{k}{d}$ repetitions of the linear strings of length d that have period d, where $d|k$. Therefore, the total number of linear strings of length k where the objects are chosen from m types is $\sum_{d|k} dg(d) = m^k$. Applying the Möbius inversion formula to m^k and g yields $g(k) = \frac{1}{k}\sum_{d|k}\mu(d)m^{k/d}$. So the total number of circular permutations of length n where the elements are chosen from an alphabet of size m is $\sum_{d|n} g(d)$, which is equal to

$$\textstyle\sum_{k|n}\left(\frac{1}{k}\sum_{d|k}\mu(d)m^{k/d}\right).$$

3. *Circular permutations with repetitions and specified numbers of each type of object*: Suppose there are a total of n objects of t types, with a_i of type i $(i = 1, \ldots, t)$, where $a_1 + \cdots + a_t = n$. If $a = \gcd(a_1, \ldots, a_t)$, these circular permutations can be generated as in Example 2 by taking a circular permutation of period d (where $d|a$) with $\frac{a_i d}{n}$ objects of type i $(i = 1, \ldots, t)$, breaking it open, and laying it end-to-end $\frac{n}{d}$ times. Let $g(k)$ be the number of such circular permutations of length k that have period k. Then the total number of linear strings of length n with a_i objects of type i is given by $\sum_{d|a} dg(d) = \frac{n!}{a_1!\ldots a_t!}$. By the Möbius inversion formula,

$$g(k) = \tfrac{1}{k}\textstyle\sum_{d|a}\mu(d)\frac{(k/d)!}{(a_1/d)!(a_2/d)!\ldots(a_t/d)!}.$$

Summing $g(k)$ over all divisors of a gives the desired total number of circular permutations:

$$\textstyle\sum_{k|a} g(k) = \sum_{k|a}\left(\frac{1}{k}\sum_{d|a}\mu(d)\frac{(k/d)!}{(a_1/d)!\ldots(a_t/d)!}\right).$$

2.8 YOUNG TABLEAUX

Arrays called Young tableaux were introduced by the Reverend Alfred Young (1873–1940). These arrays are used in combinatorics and the theories of symmetric functions, which are the subject of this section. Young tableaux are also used in the analysis of representations of the symmetric group. They make it possible to approach many results about representation theory from a concrete combinatorial viewpoint.

2.8.1 TABLEAUX COUNTING FORMULAS

Definitions:

The ***hook*** $H_{i,j}$ of cell (i,j) in the Ferrers diagram for a partition λ is the set

$$\{\,(k,j) \in \lambda \mid k \geq i\,\} \;\cup\; \{\,(i,k) \in \lambda \mid k \geq j\,\};$$

that is, the set consisting of the cell (i,j), all cells in its row to its right, and all cells in its column below it.

The ***hooklength*** $h_{i,j}$ of cell (i,j) is the number $|H_{i,j}|$ of cells in its hook.

A ***Young tableau*** is an array obtained by replacing each cell of the Ferrers diagram by a positive integer.

The ***shape*** of a Young tableau is the partition corresponding to the underlying Ferrers diagram. The notation $\lambda \vdash n$ indicates that λ partitions the number n.

A Young tableau is ***semistandard*** (an ***SSYT***) if the entries in each row are weakly increasing and the entries in each column are strictly increasing.

A semistandard Young tableau of shape $\lambda \vdash n$ is ***standard*** (an ***SYT***) if each number $1,\ldots,n$ occurs exactly once as an entry. The number of SYT of shape λ is denoted f_λ.

If G is a group (see §5.2) then an ***involution*** is an element $g \in G$ such that g^2 is the identity. The number of involutions in the symmetric group S_n (or Σ_n) (the group of all permutations on the set $\{1,2,\ldots,n\}$) is denoted $\text{inv}(n)$.

The following table summarizes notation for Young tableaux:

notation	*meaning*
$\lambda = (\lambda_1,\ldots,\lambda_l)$	partition (with parts $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_l$)
$\lambda \vdash n$	λ partitions the number n
(i,j)	cell in a Ferrers diagram
$H_{i,j}$	hook of cell (i,j)
$h_{i,j}$	hooklength of hook $H_{i,j}$
f_λ	number of SYT of shape λ
$\text{inv}(n)$	number of involutions in S_n

Facts:

1. *Frame-Robinson-Thrall hook formula* (1954): The number of SYT of fixed shape λ is

$$f_\lambda = \frac{n!}{\prod_{(i,j)\in\lambda} h_{i,j}}.$$

2. *Frobenius determinantal formula* (1900): The number of SYT of fixed shape $\lambda = (\lambda_1,\ldots,\lambda_l)$ is the determinant

$$f_\lambda = n! \left| \frac{1}{(\lambda_i + j - i)!} \right|_{1\leq i,j\leq l}.$$

3. Summations involving the number of SYT:

$$\sum_{\lambda\vdash n} f_\lambda = \text{inv}(n), \qquad \sum_{\lambda\vdash n} f_\lambda^2 = n!.$$

4. Young tableaux can be used to find the number of permutations with specified lengths for their longest increasing subsequences and longest decreasing subsequences [Be71].

Examples:

1. If $\lambda = (3, 2)$ then a complete list of SYT is

$$\begin{array}{ccc}1&2&3\\4&5&\end{array}\qquad\begin{array}{ccc}1&2&4\\3&5&\end{array}\qquad\begin{array}{ccc}1&2&5\\3&4&\end{array}\qquad\begin{array}{ccc}1&3&4\\2&5&\end{array}\qquad\begin{array}{ccc}1&3&5\\2&4&\end{array}$$

2. If $\lambda = (2, 2)$ then a complete list of SSYT with entries at most 3 is

$$\begin{array}{cc}1&1\\2&2\end{array}\qquad\begin{array}{cc}1&1\\3&3\end{array}\qquad\begin{array}{cc}2&2\\3&3\end{array}\qquad\begin{array}{cc}1&1\\2&3\end{array}\qquad\begin{array}{cc}1&2\\2&3\end{array}\qquad\begin{array}{cc}1&2\\3&3\end{array}$$

3. For the partition $(3, 2)$, $H_{1,1} = \{(1, 1),\ (2, 1),\ (1, 2),\ (1, 3)\}$. In the following diagram each cell of $(3, 2)$ is replaced with its hooklength.

$$\begin{array}{ccc}4&3&1\\2&1&\end{array}$$

The hook formula (Fact 1) gives the number of SYT of shape $(3, 2)$: $f_{(3,2)} = \frac{5!}{4\cdot3\cdot2\cdot1^2} = 5$. The determinantal formula (Fact 2) gives the same result:

$$f_{(3,2)} = 5!\begin{vmatrix}\frac{1}{3!} & \frac{1}{4!}\\ \frac{1}{1!} & \frac{1}{2!}\end{vmatrix} = 5.$$

4. For the partitions of $n = 3$, $f_{(3)} = 1$, $f_{(2,1)} = 2$, $f_{(1,1,1)} = 1$, so the summation formulas become

$$\sum_{\lambda\vdash 3} f_\lambda = 4 = \mathrm{inv}(3);$$
$$\sum_{\lambda\vdash 3} f_\lambda^2 = 6 = 3!.$$

2.8.2 TABLEAUX ALGORITHMS

Definitions:

An ***inner corner*** of a partition λ is a cell $(i, j) \in \lambda$ such that $(i + 1, j), (i, j + 1) \notin \lambda$.

An ***outer corner*** of a partition λ is a cell $(i, j) \notin \lambda$ such that $(i - 1, j), (i, j - 1) \in \lambda$.

Facts:

1. The Greene-Nijenhuis-Wilf algorithm (1979) (Algorithm 1) successively finds inner corners of a tableau of shape λ, eventually producing a random tableau of the specified shape.

```
Algorithm 1: Greene-Nijenhuis-Wilf.
  input: a shape $\lambda_I$ such that $\lambda_I \vdash n$
  output: a standard Young tableau of shape $\lambda_I$, uniformly at random
  $\lambda := \lambda_I$
```

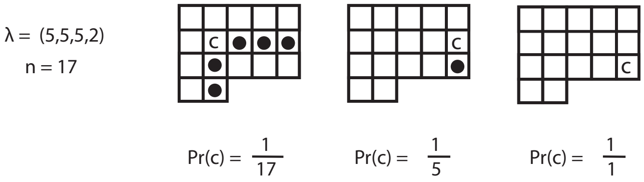
```
while $\lambda$ is nonempty
   {Find an inner corner $(i,j) \in \lambda$}
   choose (with probability $\frac{1}{|\lambda|}$) any cell $(i,j) \in \lambda$
   while the current cell $(i,j)$ is not an inner corner
      choose (with probability $\frac{1}{h_{i,j}}$) a pair $(i',j') \in H_{i,j} - \{(i,j)\}$
      $(i,j) := (i',j')$
   assign label $n$ to inner corner $(i,j)$
   $\lambda := \lambda - \{(i,j)\}$
```

2. The Robinson-Schensted algorithm (1938, 1961) (Algorithm 2) constructs a pair (P,Q) of SYT of the same shape, following a specified permutation π that guides the insertion of entries into the two tableaux. At each step i, the entry π_i is inserted into the tableau P whereas i is inserted (at the same position) into Q.

```
Algorithm 2:  Robinson-Schensted.
input: a permutation $\pi \in S_n$ where $\pi = \begin{pmatrix} 1 & 2 & \cdots & n \\ \pi_1 & \pi_2 & \cdots & \pi_n \end{pmatrix}$
output: a pair $(P,Q)$ of standard Young tableaux of the same shape $\lambda \vdash n$
$P_0 := \emptyset$; $Q_0 := \emptyset$
for $k := 1$ to $n$
   $r := 1$; $c := 1$; $b := \pi_k$; $P_k := P_{k-1}$; $exit :=$ FALSE
   while $exit =$ FALSE
      {Find next insertion row $r$ in tableau $P_k$}
      while $row_r(P_k) \neq \emptyset$ and $\pi_j > \max\{row_r(P_k)\}$
         $r := r + 1$
      {Find next insertion column $c$ in tableau $P_k$}
      $c := 1$
      while $P_k[r,c] \neq \emptyset$ and $\pi_k < P_k[r,c]$
         $c := c + 1$
      {Insert $b$}
      if $P_k[r,c] = \emptyset$ then
         $P_k[r,c] := b$; $exit =$ TRUE
      else
         $bb := P_k[r,c]$; $P_k[r,c] := b$; $b := bb$
   $Q_k[r,c] := k$
$P := P_n$; $Q := Q_n$
```

Examples:

1. The diagrams in the following figure illustrate a plausible sequence of current cells chosen as the first step of Algorithm 1, in order to find an inner corner of a tableau of shape $\lambda = (5,5,5,2)$.



2. The permutation $\pi = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 6 & 2 & 3 & 1 & 7 & 5 & 4 \end{pmatrix}$ yields the following sequence of tableaux pairs (P_k, Q_k) during the execution of Algorithm 2.

SEQUENCES

INTRODUCTION

Sequences of integers occur regularly in combinatorial applications. For example, the solution to a counting problem that depends on a parameter k can be viewed as the kth term of a sequence. This chapter provides a guide to particular sequences that arise in applied settings. Such (infinite) sequences can frequently be represented in a finite form. Specifically, sequences can be expressed using generating functions, recurrence relations, or by an explicit formula for the kth term of the sequence.

GLOSSARY

antidifference (of a function f): any function g such that $\Delta g = f$. It is the discrete analogue of antidifferentiation.

ascent (in a permutation π): any index i such that $\pi_i < \pi_{i+1}$.

asymptotic equality (of functions): the function $f(n)$ is asymptotic to $g(n)$, written $f(n) \sim g(n)$, if $f(n) \neq 0$ for sufficiently large n and $\lim_{n\to\infty} \frac{g(n)}{f(n)} = 1$.

Bernoulli numbers: the numbers B_n produced by the recursive definition $B_0 = 1$, $\sum_{j=0}^{n} \binom{n+1}{j} B_j = 0$, $n \geq 1$.

Bernoulli polynomials: the polynomial $B_m(x) = \sum_{k=0}^{m} \binom{m}{k} B_k x^{m-k}$ where B_k is the kth Bernoulli number.

big oh (of the function f): the set of all functions that do not grow faster than some constant multiple of f, written $O(f(n))$.

big omega (of the function f): the set of all functions that grow at least as fast as some constant multiple of f, written $\Omega(f(n))$.

big theta (of the function f): the set of all functions that grow roughly as fast as some constant multiple of f, written $\Theta(f(n))$.

binomial convolution (of the sequences $\{a_n\}$ and $\{b_n\}$): the sequence whose rth term is formed by summing products of the form $\binom{r}{k} a_k b_{r-k}$.

Catalan number: the number $C_n = \frac{1}{n+1}\binom{2n}{n}$.

characteristic equation: an equation derived from a linear recurrence relation with constant coefficients, whose roots are used to construct solutions to the recurrence relation.

closed form (for a sum): an algebraic expression for the value of a sum with variable limits, which has a fixed number of terms; hence the time needed to calculate it does not grow with the size of the set or interval of summation.

convolution (of the sequences $\{a_n\}$ and $\{b_n\}$): the sequence whose rth term is formed by summing products of the form $a_k b_{r-k}$ where $0 \leq k \leq r$.

de Bruijn sequence: a circular ordering of letters from a fixed alphabet with p letters such that each n consecutive letters (wrapping around from the end of the sequence to the beginning, if necessary) forms a different word.

difference operator: the operator Δ where $\Delta f(x) = f(x+1) - f(x)$ on integer or real-valued functions. It is the discrete analogue of the differentiation operator.

difference sequence (for the sequence $A = \{\, a_j \mid j = 0, 1, \ldots \}$): the sequence $\Delta A = \{\, a_{j+1} - a_j \mid j = 0, 1, \ldots \}$.

difference table (for a function f): a table whose kth row is the kth difference sequence for f.

discordant permutation: a permutation that assigns to every element an image different from those assigned by all other members of a given set of permutations.

dissimilar hypergeometric terms: terms in two hypergeometric series such that their ratio is not a rational function.

divide-and-conquer algorithm: a recursive procedure that solves a given problem by first breaking it into smaller subproblems (of nearly equal size) and then combining their respective solutions.

doubly hypergeometric: a property of function $F(n,k)$ that $\frac{F(n+1,k)}{F(n,k)}$ and $\frac{F(n,k+1)}{F(n,k)}$ are rational functions of n and k.

Eulerian number: the number of permutations of $\{1, 2, \ldots, n\}$ with exactly k ascents.

excedance (of a permutation π): any index i such that $\pi_i > i$.

exponential generating function (for the sequence $a_0, a_1, a_2, \ldots$): the function $f(x)$ $= a_0 + a_1 x + a_2 \frac{x^2}{2!} + \cdots$ or any equivalent closed form expression.

falling power (of x): the product $x^{\underline{n}} = x(x-1)(x-2)\ldots(x-n+1)$ of n successive descending factors, starting with x; the discrete analogue of exponentiation.

Fibonacci numbers: the numbers F_n produced by the recursive definition $F_0 = 0$, $F_1 = 1$, $F_n = F_{n-1} + F_{n-2}$ if $n \geq 2$.

figurate number: the number of cells in an array of cells bounded by some regular geometrical figure.

first-order linear recurrence relation with constant coefficients: an equation of the form $C_0 a_n + C_1 a_{n-1} = f(n)$, $n \geq 1$, with C_0 and C_1 nonzero real constants.

generating function (for the sequence $a_0, a_1, a_2, \ldots$): the function $f(x) = a_0 + a_1 x + a_2 x^2 + \cdots$ or any equivalent closed form expression; sometimes called the *ordinary* generating function for the sequence.

geometric series: an infinite series where the ratio between two consecutive terms is a constant.

Gray code (of size n): a circular ordering of all binary strings of length n in which adjacent strings differ in exactly one bit.

harmonic number: the sum $H_n = \sum_{i=1}^{n} \frac{1}{i}$, which is the discrete analogue of the natural logarithm.

homogeneous recurrence relation: a recurrence relation satisfied by the identically zero sequence.

hypergeometric series: a series where the ratio of two consecutive terms is a rational function.

indefinite sum (of the function f): the family of all antidifferences of f.

Lah coefficients: the coefficients resulting from expressing the rising factorial in terms of the falling factorials.

linear recurrence relation with constant coefficients: an equation of the form $C_0a_n + C_1a_{n-1} + \cdots + C_ka_{n-k} = f(n)$, $n \geq k$, where the C_i are real constants with C_0 and C_k nonzero.

little oh (of the function f): the set of all functions that grow slower than every constant multiple of f, written $o(f(n))$.

little omega (of the function f): the set of all functions that grow faster than every constant multiple of f, written $\omega(f(n))$.

Lucas numbers: the numbers L_n produced by the recursive definition $L_0 = 2$, $L_1 = 1$, $L_n = L_{n-1} + L_{n-2}$ if $n \geq 2$.

nonhomogeneous recurrence relation: a recurrence relation that is not homogeneous.

polyomino: a connected configuration of regular polygons (e.g., triangles, squares, or hexagons) in the plane, generalizing a domino.

power sum: the sum of the kth powers of the integers $1, 2, \ldots, n$.

radius of convergence (for the series $\sum a_nx^n$): the number r $(0 \leq r \leq \infty)$ such that the series converges for all $|x| < r$ and diverges for all $|x| > r$.

Ramsey number: the number $R(m, n)$ defined as the smallest positive integer k with the following property: if S is a set of size k and the 2-element subsets of S are partitioned into two collections, C_1 and C_2, then there is a subset of S of size m such that each of its 2-element subsets belong to C_1 or there is a subset of S of size n such that each of its 2-element subsets belong to C_2.

recurrence relation: an equation expressing a term of a sequence as a function of prior terms in the sequence.

rising power (of x): the product $x^{\overline{n}} = x(x+1)(x+2)\ldots(x+n-1)$ of n successive ascending terms, starting with x.

second-order linear recurrence relation with constant coefficients: an equation of the form $C_0a_n + C_1a_{n-1} + C_2a_{n-2} = f(n)$, $n \geq 2$, where C_0, C_1, C_2 are real constants with C_0 and C_2 nonzero.

sequence: a function from $\{0, 1, 2, \ldots\}$ to the real numbers (often the integers).

shift operator: the operator E defined by $Ef(x) = f(x+1)$ on integer or real-valued functions.

similar hypergeometric terms: terms in two hypergeometric series such that their ratio is a rational function.

standardized form (for a sum): a sum over an integer interval, in which the lower limit of the summation is zero.

Stirling's approximation formula: the asymptotic estimate $\sqrt{2\pi n}(n/e)^n$ for $n!$.

tangent numbers: numbers generated by the exponential generating function $\tan x$.

3.1 SPECIAL SEQUENCES

3.1.1 REPRESENTATIONS OF SEQUENCES

A given infinite sequence $a_0, a_1, a_2, \ldots$ can often be represented in a more useful or more compact form. Namely, there may be a closed form expression for a_n as a function of n, the terms of the sequence may appear as coefficients in a simple generating function, or the sequence may be specified by a recurrence relation. Each representation has advantages, in either defining the sequence or establishing information about its terms.

Definitions:

A ***sequence*** $\{\, a_n \mid n \geq 0 \,\}$ is a function from the set of nonnegative integers to the real numbers (often the integers). The ***terms*** of the sequence $\{\, a_n \mid n \geq 0 \,\}$ are the values $a_0, a_1, a_2, \ldots$.

A ***closed form*** for the sequence $\{a_n\}$ is an algebraic expression for a_n as a function of n.

A ***recurrence relation*** (§3.3) is an equation expressing a term of a sequence as a function of prior terms in the sequence. A ***solution*** of a recurrence relation is a sequence whose terms satisfy the relation.

The (***ordinary***) ***generating function*** (§3.2.1) for the sequence $\{a_n\}$ is the function $f(x) = \sum\limits_{i=0}^{\infty} a_i x^i$ or any equivalent closed form expression.

The ***exponential generating function*** (§3.2.2) for the sequence $\{a_n\}$ is the function $g(x) = \sum\limits_{i=0}^{\infty} a_i \frac{x^i}{i!}$ or any equivalent closed form expression.

Facts:

1. An important way in which many sequences are represented is by using a recurrence relation. Although not all sequences can be represented by useful recurrence relations, many sequences that arise in the solution of counting problems can be so represented.

2. An important way to study a sequence is by using its generating function. Information about terms of the sequence can often be obtained by manipulating the generating function.

Examples:

1. The Fibonacci numbers F_n (§3.1.2) arise in many applications and are given by the sequence $0, 1, 1, 2, 3, 5, 8, 13, \ldots$. This infinite sequence can be finitely encoded by means of the recurrence relation

$$F_n = F_{n-1} + F_{n-2}, \quad n \geq 2, \quad \text{with } F_0 = 0 \text{ and } F_1 = 1.$$

Alternatively, a closed form expression for this sequence is given by

$$F_n = \tfrac{1}{\sqrt{5}} \Big[\Big(\tfrac{1+\sqrt{5}}{2} \Big)^n - \Big(\tfrac{1-\sqrt{5}}{2} \Big)^n \Big], \quad n \geq 0.$$

The Fibonacci numbers can be represented in a third way, via the generating function $f(x) = \frac{x}{1-x-x^2}$. Namely, when this rational function is expanded in terms of powers of

x, the resulting coefficients generate the values F_n:

$$\frac{x}{1-x-x^2} = 0x^0 + 1x^1 + 1x^2 + 2x^3 + 3x^4 + 5x^5 + 8x^6 + 13x^7 + \cdots .$$

2. Table 1 gives closed form expressions for the generating functions of several combinatorial sequences discussed in this *Handbook*. In this table, r is any real number. Generating functions for other sequences can be found in §3.2.1, Tables 1 and 2.

Table 1: Generating functions for particular sequences.

sequence	*notation*	*reference*	*closed form*
$1, 2, 3, 4, 5, \ldots$	$\{n\}$		$\frac{1}{(1-x)^2}$
$1^2, 2^2, 3^2, 4^2, 5^2, \ldots$	$\{n^2\}$		$\frac{1+x}{(1-x)^3}$

3.1.2 FIBONACCI NUMBERS

Fibonacci numbers form an important sequence encountered in biology, physics, number theory, computer science, and combinatorics. [BePhHo10], [Gr12], [PhBeHo01], [Va07]

Definitions:

The ***Fibonacci numbers*** $F_0, F_1, F_2, \ldots$ are produced by the recursive definition $F_0 = 0$, $F_1 = 1$, $F_n = F_{n-1} + F_{n-2}$, $n \geq 2$.

A ***generalized Fibonacci sequence*** is any sequence $G_0, G_1, G_2, \ldots$ such that $G_n = G_{n-1} + G_{n-2}$ for $n \geq 2$.

The ***Lucas numbers*** $L_0, L_1, L_2, \ldots$ are produced by the recursive definition $L_0 = 2$, $L_1 = 1$, $L_n = L_{n-1} + L_{n-2}$, $n \geq 2$. (François Lucas, 1842–1891)

Facts:

1. The Fibonacci numbers F_n and Lucas numbers L_n for $n = 0, 1, 2, \ldots, 50$ are shown in the following table.

2. The Fibonacci numbers were initially studied by Leonardo of Pisa (c. 1170–1250), who was the son of Bonaccio; consequently these numbers have been called *Fibonacci* numbers after Leonardo, the son of Bonaccio (Filius Bonaccii).

3. $\lim\limits_{n\to\infty} \frac{F_{n+1}}{F_n} = \lim\limits_{n\to\infty} \frac{L_{n+1}}{L_n} = \frac{1}{2}(1+\sqrt{5}) \approx 1.61803$, the *golden ratio.*

n	F_n	L_n	n	F_n	L_n	n	F_n	L_n
0	0	2	17	1,597	3,571	34	5,702,887	12,752,043
1	1	1	18	2,584	5,778	35	9,227,465	20,633,239

4. Fibonacci numbers arise in numerous applications from various areas. For example, they occur in models of population growth of rabbits (Example 3), in modeling plant growth (Example 8), in counting the number of spanning trees of wheel graphs of length n (Example 12), in counting the number of bit strings of length n without consecutive 0s (Example 13), and in many other contexts. See [Gr12] and [Va07] for additional applications of the Fibonacci numbers. The journal *Fibonacci Quarterly* is devoted to the study of the Fibonacci numbers and related topics, a tribute to how widely the Fibonacci numbers arise in mathematics and its applications to other areas. Further readings about the Fibonacci numbers can be found at

- `http://www.maths.surrey.ac.uk/hosted-sites/R.Knott/Fibonacci/fibrefs.html`.

5. Many properties of the Fibonacci numbers were derived by F. Lucas, who also is responsible for naming them the "Fibonacci" numbers.

6. *Binet form* (Jacques Binet, 1786–1856): If $\alpha = \frac{1}{2}(1+\sqrt{5})$ and $\beta = \frac{1}{2}(1-\sqrt{5})$ then

$$F_n = \tfrac{\alpha^n - \beta^n}{\sqrt{5}} = \tfrac{\alpha^n - \beta^n}{\alpha - \beta}, \qquad F_n \sim \tfrac{\alpha^n}{\sqrt{5}}.$$

Also,

$$L_n = \alpha^n + \beta^n, \qquad L_n \sim \alpha^n.$$

7. $F_n = \frac{1}{2}(F_{n-2} + F_{n+1})$ for all $n \geq 2$. That is, each Fibonacci number is the average of the terms occurring two places before and one place after it in the sequence.

8. $L_n = \frac{1}{2}(L_{n-2} + L_{n+1})$ for all $n \geq 2$. That is, each Lucas number is the average of the terms occurring two places before and one place after it in the sequence.

9. $F_0 + F_1 + F_2 + \cdots + F_n = F_{n+2} - 1$ for all $n \geq 0$.

10. $F_0 - F_1 + F_2 - \cdots + (-1)^n F_n = (-1)^n F_{n-1} - 1$ for all $n \geq 1$.

11. $F_1 + F_3 + F_5 + \cdots + F_{2n-1} = F_{2n}$ for all $n \geq 1$.

12. $F_0 + F_2 + F_4 + \cdots + F_{2n} = F_{2n+1} - 1$ for all $n \geq 0$.

13. $F_0^2 + F_1^2 + F_2^2 + \cdots + F_n^2 = F_n F_{n+1}$ for all $n \geq 0$.

14. $F_1F_2 + F_2F_3 + F_3F_4 + \cdots + F_{2n-1}F_{2n} = F_{2n}^2$ for all $n \geq 1$.

15. $F_1F_2 + F_2F_3 + F_3F_4 + \cdots + F_{2n}F_{2n+1} = F_{2n+1}^2 - 1$ for all $n \geq 1$.

16. If $k \geq 1$ then $F_{n+k} = F_kF_{n+1} + F_{k-1}F_n$ for all $n \geq 0$.

17. *Cassini's identity*: $F_{n+1}F_{n-1} - F_n^2 = (-1)^n$ for all $n \geq 1$. (Jean Dominique Cassini, 1625–1712)

18. $F_{n+1}^2 + F_n^2 = F_{2n+1}$ for all $n \geq 0$.

19. $F_{n+2}^2 - F_{n+1}^2 = F_nF_{n+3}$ for all $n \geq 0$.

20. $F_{n+2}^2 - F_n^2 = F_{2n+2}$ for all $n \geq 0$.

21. $F_{n+2}^3 + F_{n+1}^3 - F_n^3 = F_{3n+3}$ for all $n \geq 0$.

22. $\gcd(F_n, F_m) = F_{\gcd(n,m)}$. This implies that F_n and F_{n+1} are relatively prime, and that F_k divides F_{nk}.

23. Fibonacci numbers arise as sums of diagonals in Pascal's triangle (§2.3.2):

$$F_{n+1} = \sum_{j=0}^{\lfloor n/2 \rfloor} \binom{n-j}{j} \text{ for all } n \geq 0.$$

24. $F_{3n} = \sum_{j=0}^{n} \binom{n}{j} 2^j F_j$ for all $n \geq 0$.

25. The Fibonacci sequence $F_0, F_1, F_2, \ldots$ has the generating function $\frac{x}{1-x-x^2}$.

26. Fibonacci numbers with negative indices can be defined using the recursive definition $F_{n-2} = F_n - F_{n-1}$. Then $F_{-n} = (-1)^{n-1}F_n$, $n \geq 1$.

27. The units digits of the Fibonacci numbers form a sequence that repeats after 60 terms. (Joseph Lagrange, 1736–1813)

28. The number of binary strings of length n that contain no consecutive 0s is counted by F_{n+2}. (See §3.3.2, Example 12.)

29. $L_0 + L_1 + L_2 + \cdots + L_n = L_{n+2} - 1$ for all $n \geq 0$.

30. $L_0^2 + L_1^2 + L_2^2 + \cdots + L_n^2 = L_nL_{n+1} + 2$ for all $n \geq 0$.

31. $L_n = F_{n-1} + F_{n+1}$, $n \geq 1$. Hence, any formula containing Lucas numbers can be translated into a formula involving Fibonacci numbers.

32. The Lucas sequence $L_0, L_1, L_2, \ldots$ has the generating function $\frac{2-x}{1-x-x^2}$.

33. Lucas numbers with negative indices can be defined by extending the recursive definition. Then $L_{-n} = (-1)^nL_n$ for all $n \geq 1$.

34. $F_n = \frac{L_{n-1}+L_{n+1}}{5}$, $n \geq 1$. Hence, any formula involving Fibonacci numbers can be translated into a formula involving Lucas numbers.

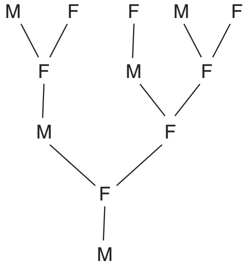
35. $2^{n+1}F_{n+1} = \sum_{i=0}^{n} 2^iL_i$ for all $n \geq 0$.

36. If $G_0, G_1, \ldots$ is a sequence of generalized Fibonacci numbers, then $F_n = F_{n-1}G_0 + F_nG_1$ for all $n \geq 1$.

Examples:

1. The Fibonacci number F_8 can be computed using the initial values $F_0 = 0$ and $F_1 = 1$ and the recurrence relation $F_n = F_{n-1} + F_{n-2}$ repeatedly: $F_2 = F_1 + F_0 = 1 + 0 = 1$, $F_3 = F_2 + F_1 = 1 + 1 = 2$, $F_4 = F_3 + F_2 = 2 + 1 = 3$, $F_5 = F_4 + F_3 = 3 + 2 = 5$, $F_6 = F_5 + F_4 = 5 + 3 = 8$, $F_7 = F_6 + F_5 = 8 + 5 = 13$, $F_8 = F_7 + F_6 = 13 + 8 = 21$.

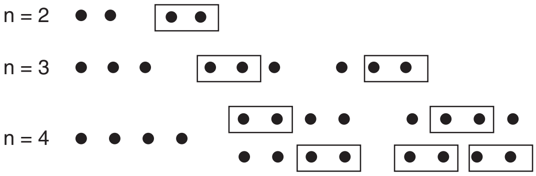
2. Each male bee (drone) is produced asexually from a female, whereas each female bee is produced from both a male and female. The ancestral tree for a single male bee is shown below. This male has one parent, two grandparents, three great grandparents, and in general F_{k+2} kth-order grandparents, $k \geq 0$.



3. *Rabbit breeding*: This problem was originally posed by Fibonacci. A single pair of immature rabbits is introduced into a habitat. It takes two months before a pair of rabbits can breed; each month thereafter each pair of breeding rabbits produces another pair. At the start of months 1 and 2, only the original pair A is present. In the third month, A as well as their newly born pair B are present; in the fourth month, A, B as well as the new pair C (progeny of A) are present; in the fifth month, A, B, C as well as the new pairs D (progeny of A) and E (progeny of B) are present. If P_n is the number of pairs present in month n, then $P_1 = 1$, $P_2 = 1$, $P_3 = 2$, $P_4 = 3$, $P_5 = 5$. In general, P_n equals the number present in the previous month P_{n-1} plus the number of breeding pairs in the previous month (which is P_{n-2}, the number present two months earlier). Thus $P_n = F_n$ for $n \geq 1$.

4. Let S_n denote the number of subsets of $\{1, 2, \ldots, n\}$ that do not contain consecutive elements. For example, when $n = 3$ the allowable subsets are $\emptyset, \{1\}, \{2\}, \{3\}, \{1, 3\}$. Therefore, $S_3 = 5$. In general, $S_n = F_{n+2}$ for $n \geq 1$.

5. Draw n dots in a line. If each domino can cover exactly two such dots, in how many ways can (nonoverlapping) dominoes be placed? The following figure shows the number of possible solutions for $n = 2, 3, 4$. To find a general expression for D_n, the number of possible placements of dominoes with n dots, consider the rightmost dot in any such placement P. If this dot is not covered by a domino, then P minus the last dot determines a solution counted by D_{n-1}. If the last dot is covered by a domino, then the last two dots in P are covered by this domino. Removing this rightmost domino then gives a solution counted by D_{n-2}. Taking into account these two possibilities $D_n = D_{n-1} + D_{n-2}$ for $n \geq 3$ with $D_1 = 1$, $D_2 = 2$. Thus $D_n = F_{n+1}$ for $n \geq 1$.



6. *Compositions*: Let T_n be the number of ordered compositions (§2.5.1) of the positive integer n into summands that are odd. For example, $4 = 1 + 3 = 3 + 1 = 1 + 1 + 1 + 1$ and $5 = 5 = 1 + 1 + 3 = 1 + 3 + 1 = 3 + 1 + 1 = 1 + 1 + 1 + 1 + 1$. Therefore, $T_4 = 3$ and $T_5 = 5$. In general, $T_n = F_n$ for $n \geq 1$.

7. *Compositions*: Let B_n be the number of ordered compositions (§2.5.1) of the positive integer n into summands that are either 1 or 2. For example, $3 = 1+2 = 2+1 = 1+1+1$

and $4 = 2+2 = 1+1+2 = 1+2+1 = 2+1+1 = 1+1+1+1$. Therefore, $B_3 = 3$ and $B_4 = 5$. In general, $B_n = F_{n+1}$ for $n \geq 1$.

8. *Botany*: It has been observed in pine cones (and other botanical structures) that the number of rows of scales winding in one direction is a Fibonacci number while the number of rows of scales winding in the other direction is an adjacent Fibonacci number.

9. *Continued fractions*: The continued fraction $1 + \frac{1}{1} = \frac{2}{1}$, the continued fraction $1 + \frac{1}{1+\frac{1}{1}} = \frac{3}{2}$ and the continued fraction $1 + \frac{1}{1+\frac{1}{1+\frac{1}{1}}} = \frac{5}{3}$. In general, a continued fraction composed entirely of 1s equals the ratio of successive Fibonacci numbers.

10. *Independent sets on a path*: Consider a path graph on vertices $1, 2, \ldots, n$, with edges joining vertices i and $i+1$ for $i = 1, 2, \ldots, n-1$. An independent set of vertices (§8.6.3) consists of vertices no two of which are joined by an edge. By an analysis similar to that in Example 5, the number of independent sets in a path graph on n vertices equals F_{n+2}.

11. *Independent sets on a cycle*: Consider a cycle graph on vertices $1, 2, \ldots, n$, with edges joining vertices i and $i+1$ for $i = 1, 2, \ldots, n-1$ as well as vertices n and 1. Then the number of independent sets (§8.6.3) in a cycle graph on n vertices equals L_n.

12. *Spanning trees*: The number of spanning trees of the wheel graph W_n (§8.1.3) equals $L_{2n} - 2$.

13. If A is the 2×2 matrix $\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$, then $A^n = \begin{pmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{pmatrix}$ for $n \geq 1$.

3.1.3 CATALAN NUMBERS

The sequence of integers called the Catalan numbers arises in counting a variety of combinatorial structures, such as voting sequences, certain types of binary trees, paths in the plane, and triangulations of polygons.

Definitions:

The ***Catalan numbers*** $C_0, C_1, C_2, \ldots$ satisfy the nonlinear recurrence relation $C_n = C_0C_{n-1} + C_1C_{n-2} + \cdots + C_{n-1}C_0$, $n \geq 1$, with $C_0 = 1$. (See §3.3.1, Example 9.) (Eugène Catalan, 1814–1894)

Well-formed (***or balanced***) ***sequences of parentheses*** of length $2n$ are defined recursively as follows: the empty sequence is well-formed; if sequence A is well-formed so is (A); if sequences A and B are well-formed so is AB.

Well-parenthesized products of variables are defined recursively as follows: single variables are well-parenthesized; if A and B are well-parenthesized so is (AB).

Facts:

1. The first 12 Catalan numbers C_n are given in the following table.

n	0	1	2	3	4	5	6	7	8	9	10	11
C_n	1	1	2	5	14	42	132	429	1,430	4,862	16,796	58,786

2. $\lim\limits_{n\to\infty} \frac{C_{n+1}}{C_n} = 4$.

3. Catalan numbers arise in a variety of applications, such as in counting binary trees on n vertices, triangulations of a convex n-gon, and well-formed sequences of n left and n right parentheses. See the examples below as well as [Gr12] and [MiRo91].

4. $C_n = \frac{1}{n+1}\binom{2n}{n}$ for all $n \geq 0$.

5. The Catalan numbers $C_0, C_1, C_2, \ldots$ have the generating function $\frac{1-\sqrt{1-4x}}{2x}$.

6. $C_n \sim \frac{4^n}{\sqrt{\pi n^3}}$.

7. $C_n = \binom{2n}{n} - \binom{2n}{n-1} = \binom{2n-1}{n} - \binom{2n-1}{n+1}$ for all $n \geq 1$.

8. $C_{n+1} = \frac{2(2n+1)}{n+2} C_n$ for all $n \geq 0$.

Examples:

1. The number of binary trees (§9.1.2) on n vertices is C_n.

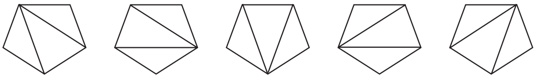
2. The number of left-right binary trees (§9.3.3) on $2n+1$ vertices is C_n.

3. The number of ordered trees (§9.1.2) on n vertices is C_{n-1}.

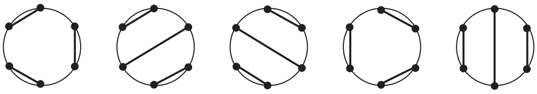
4. Suppose that a coin is tossed $2n$ times, coming up heads exactly n times and tails exactly n times. The number of sequences of tosses in which the cumulative number of heads is always at least as large as the cumulative number of tails is C_n. For example, when $n = 3$ there are $C_3 = 5$ such sequences of six tosses: HTHTHT, HTHHTT, HHTTHT, HHTHTT, HHHTTT.

5. In Example 4, the number of sequences of tosses in which the cumulative number of heads always exceeds the cumulative number of tails (until the very last toss) is C_{n-1}. For example, when $n = 3$ there are $C_2 = 2$ such sequences of six tosses: HHTHTT, HHHTTT.

6. *Triangulations*: Let T_n be the number of triangulations of a convex n-gon, using $n-3$ nonintersecting diagonals. For instance, the following figure shows the $T_5 = 5$ triangulations of a pentagon. In general, $T_n = C_{n-2}$ for $n \geq 3$.



7. Suppose $2n$ points are placed in fixed positions, evenly distributed on the circumference of a circle. Then there are C_n ways to join n pairs of the points so that the resulting chords do not intersect. The following figure shows the $C_3 = 5$ solutions for $n = 3$.



8. *Well-formed sequences of parentheses*: The sequence of parentheses (()()) involving three left and three right parentheses is well-formed, whereas the sequence ( )) (( ) is not syntactically meaningful. There are five such well-formed sequences in this case:

$$()()(),\ ()(()),\ (())(),\ (()()),\ ((())).$$

Notice that if each left parenthesis is replaced by an H and each right parenthesis by a T, then these five balanced sequences correspond exactly to the five coin tossing sequences listed in Example 4. In general, the number of balanced sequences involving n left and n right parentheses is C_n.

9. Consider the following procedure composed of n nested **for** loops:

```
$count$ := 0
for $i_1$ := 1 to 1
for $i_2 := 1$ to $i_1 + 1$
  for $i_3 := 1$ to $i_2 + 1$
      ⋮
      for $i_n := 1$ to $i_{n-1} + 1$
        $count := count + 1$
```

Then the value of *count* upon exit from this procedure is C_n.

10. *Well-parenthesized products*: The product $x_1x_2x_3$ (relative to some binary "multiplication" operation) can be evaluated as either $(x_1x_2)x_3$ or $x_1(x_2x_3)$. In the former, x_1 and x_2 are first combined and then the result is combined with x_3. In the latter, x_2 and x_3 are first combined and then the result is combined with x_1. Let P_n indicate the number of ways to evaluate the product $x_1x_2\ldots x_n$ of n variables, using a binary operation. Note that $P_3 = 2$. In general, $P_n = C_{n-1}$. This was the problem originally studied by Catalan. (See §3.3.1, Example 9.)

11. The numbers $1, 2, \ldots, 2n$ are to be placed in the $2n$ positions of an $2 \times n$ array $A = (a_{ij})$. Such an arrangement is *monotone* if the values increase within each row and within each column. Then there are C_n ways to form a monotone $2 \times n$ array containing the entries $1, 2, \ldots, 2n$. For instance, the following is one of the $C_4 = 14$ monotone 2×4 arrays:

$$A = \begin{pmatrix} 1 & 3 & 5 & 6 \\ 2 & 4 & 7 & 8 \end{pmatrix}.$$

3.1.4 BERNOULLI NUMBERS AND POLYNOMIALS

The Bernoulli numbers are important in obtaining closed form expressions for the sums of powers of integers. These numbers also arise in expansions involving other combinatorial sequences.

Definitions:

The ***Bernoulli numbers*** B_n satisfy the recurrence relation $\sum_{j=0}^{n} \binom{n+1}{j} B_j = 0$ for all $n \geq 1$, with $B_0 = 1$. (Jakob Bernoulli, 1654–1705)

The ***Bernoulli polynomials*** $B_m(x)$ are given by $B_m(x) = \sum_{k=0}^{m} \binom{m}{k} B_k x^{m-k}$.

Facts:

1. The first 14 Bernoulli numbers B_n are shown in the following table.

n	0	1	2	3	4	5	6	7	8	9	10	11	12	13
B_n	1	$-\frac{1}{2}$	$\frac{1}{6}$	0	$-\frac{1}{30}$	0	$\frac{1}{42}$	0	$-\frac{1}{30}$	0	$\frac{5}{66}$	0	$-\frac{691}{2{,}730}$	0

2. $B_{2k+1} = 0$ for all $k \geq 1$.

3. The nonzero Bernoulli numbers alternate in sign.

4. $B_n = B_n(0)$.

5. The Bernoulli numbers have the exponential generating function $\sum_{n=0}^{\infty} B_n \frac{x^n}{n!} = \frac{x}{e^x - 1}$.

6. The Bernoulli numbers can be expressed in terms of the Stirling subset numbers (§2.5.2): $B_n = \sum_{j=0}^{n} (-1)^j \genfrac\{\}{0pt}{}{n}{j} \frac{j!}{j+1}$ for all $n \geq 0$.

7. The Bernoulli numbers appear as coefficients in the Maclaurin expansion of $\tan x$, $\cot x$, $\csc x$, $\tanh x$, $\coth x$, and $\operatorname{csch} x$.

8. The Bernoulli polynomials can be used to obtain closed form expressions for the sum of powers of the first n positive integers. (See §3.5.4.)

9. The first 14 Bernoulli polynomials $B_m(x)$ are shown in the following table.

n	$B_n(x)$
0	1
1	$x - \frac{1}{2}$
2	$x^2 - x + \frac{1}{6}$
3	$x^3 - \frac{3}{2}x^2 + \frac{1}{2}x$
4	$x^4 - 2x^3 + x^2 - \frac{1}{30}$
5	$x^5 - \frac{5}{2}x^4 + \frac{5}{3}x^3 - \frac{1}{6}x$
6	$x^6 - 3x^5 + \frac{5}{2}x^4 - \frac{1}{2}x^2 + \frac{1}{42}$
7	$x^7 - \frac{7}{2}x^6 + \frac{7}{2}x^5 - \frac{7}{6}x^3 + \frac{1}{6}x$
8	$x^8 - 4x^7 + \frac{14}{3}x^6 - \frac{7}{3}x^4 + \frac{2}{3}x^2 - \frac{1}{30}$
9	$x^9 - \frac{9}{2}x^8 + 6x^7 - \frac{21}{5}x^5 + 2x^3 - \frac{3}{10}x$
10	$x^{10} - 5x^9 + \frac{15}{2}x^8 - 7x^6 + 5x^4 - \frac{3}{2}x^2 + \frac{5}{66}$
11	$x^{11} - \frac{11}{2}x^{10} + \frac{55}{6}x^9 - 11x^7 + 11x^5 - \frac{11}{2}x^3 + \frac{5}{6}x$
12	$x^{12} - 6x^{11} + 11x^{10} - \frac{33}{2}x^8 + 22x^6 - \frac{33}{2}x^4 + x^2 - \frac{691}{2{,}730}$
13	$x^{13} - \frac{13}{2}x^{12} + 13x^{11} - \frac{143}{6}x^9 + \frac{286}{7}x^7 - \frac{429}{10}x^5 + \frac{65}{3}x^3 - \frac{691}{210}x$

10. $\int_0^1 B_m(x)\,dx = 0$ for all $m \geq 1$.

11. $\frac{dB_m(x)}{dx} = mB_{m-1}(x)$ for all $m \geq 1$.

12. $B_{m+1}(x+1) - B_{m+1}(x) = (m+1)x^m$ for all $m \geq 0$.

13. The Bernoulli polynomials have the exponential generating function given by $\sum_{m=0}^{\infty} B_m(x)\frac{t^m}{m!} = \frac{te^{xt}}{e^t-1}$.

3.1.5 EULERIAN NUMBERS

Eulerian numbers are important in counting numbers of permutations with certain numbers of increases and decreases.

Definitions:

Let $\pi = (\pi_1, \pi_2, \ldots, \pi_n)$ be a permutation of $\{1, 2, \ldots, n\}$.

An ***ascent*** of the permutation π is any index i $(1 \leq i < n)$ such that $\pi_i < \pi_{i+1}$. A ***descent*** of the permutation π is any index i $(1 \leq i < n)$ such that $\pi_i > \pi_{i+1}$.

An ***excedance*** of the permutation π is any index i $(1 \leq i \leq n)$ such that $\pi_i > i$. A ***weak excedance*** of the permutation π is any index i $(1 \leq i \leq n)$ such that $\pi_i \geq i$.

The ***Eulerian number*** $E(n,k)$, also written $\left\langle {n \atop k} \right\rangle$, is the number of permutations of $\{1, 2, \ldots, n\}$ with exactly k ascents.

Facts:

1. $E(n,k)$ is the number of permutations of $\{1,2,\ldots,n\}$ with exactly k descents.

2. $E(n,k)$ is the number of permutations of $\{1,2,\ldots,n\}$ with exactly k excedances.

3. $E(n,k)$ is the number of permutations of $\{1,2,\ldots,n\}$ with exactly $k+1$ weak excedances.

4. The Eulerian numbers can be used to obtain closed form expressions for the sum of powers of the first n positive integers (§3.5.4).

5. Eulerian numbers $E(n,k)$ $(1 \le n \le 10,\ 0 \le k \le 8)$ are given in the following table.

$n\backslash k$	0	1	2	3	4	5	6	7	8
1	1								
2	1	1							
3	1	4	1						
4	1	11	11	1					
5	1	26	66	26	1				
6	1	57	302	302	57	1			
7	1	120	1,191	2,416	1,191	120	1		
8	1	247	4,293	15,619	15,619	4,293	247	1	
9	1	502	14,608	88,234	156,190	88,234	14,608	502	1
10	1	1,013	47,840	455,192	1,310,354	1,310,354	455,192	47,840	1,013

6. $E(n,0) = E(n,n-1) = 1$ for all $n \ge 1$.

7. *Symmetry*: $E(n,k) = E(n,n-1-k)$ for all $n \ge 1$.

8. $E(n,k) = (k+1)E(n-1,k) + (n-k)E(n-1,k-1)$ for all $n \ge 2$.

9. $\sum\limits_{k=0}^{n-1} E(n,k) = n!$ for all $n \ge 1$.

10. *Worpitzky's identity*: $x^n = \sum\limits_{k=0}^{n-1} E(n,k)\binom{x+k}{n}$ for all $n \ge 1$. (Julius Worpitzky, 1835–1895)

11. $E(n,k) = \sum\limits_{j=0}^{k} (-1)^j \binom{n+1}{j}(k+1-j)^n$ for all $n \ge 1$.

12. The Bernoulli numbers (§3.1.4) can be expressed as alternating sums of Eulerian numbers: $B_m = \frac{m}{2^m(2^m-1)} \sum\limits_{k=0}^{m-2} (-1)^k E(m-1,k)$ for $m \ge 2$.

13. The Stirling subset numbers (§2.5.2) can be expressed in terms of the Eulerian numbers: $\left\{ n \atop m \right\} = \frac{1}{m!} \sum\limits_{k=0}^{n-1} E(n,k)\binom{k}{n-m}$ for $n \ge m$ and $n \ge 1$.

14. The Eulerian numbers have the following (bivariate) generating function in variables x, t: $\sum\limits_{m=0}^{\infty} \sum\limits_{n=0}^{\infty} E(n,m)x^m \frac{t^n}{n!} = \frac{1-x}{e^{(x-1)t}-x}$.

Examples:

1. The permutation $\pi = (\pi_1,\pi_2,\pi_3,\pi_4) = (1,2,3,4)$ has three ascents since $1 < 2 < 3 < 4$ and it is the only permutation in S_4 with three ascents; note that $E(4,3) = 1$. There are $E(4,1) = 11$ permutations in S_4 with one ascent: $(1,4,3,2)$, $(2,1,4,3)$, $(2,4,3,1)$, $(3,1,4,2)$, $(3,2,1,4)$, $(3,2,4,1)$, $(3,4,2,1)$, $(4,1,3,2)$, $(4,2,1,3)$, $(4,2,3,1)$, and $(4,3,1,2)$.

2. The permutation $\pi = (2,4,3,1)$ has two excedances since $2 > 1$ and $4 > 2$. There are $E(4,2) = 11$ such permutations in S_4.

3. The permutation $\pi = (1,3,2)$ has two weak excedances since $1 \geq 1$ and $3 \geq 2$. There are $E(3,1) = 4$ such permutations in S_3: $(1,3,2)$, $(2,1,3)$, $(2,3,1)$, and $(3,2,1)$.

4. When $n = 3$, Worpitzky's identity (Fact 10) states that

$$x^3 = E(3,0)\tbinom{x}{3} + E(3,1)\tbinom{x+1}{3} + E(3,2)\tbinom{x+2}{3} = \tbinom{x}{3} + 4\tbinom{x+1}{3} + \tbinom{x+2}{3}.$$

This is verified algebraically since $\binom{x}{3} + 4\binom{x+1}{3} + \binom{x+2}{3} = \frac{1}{6}\big(x(x-1)(x-2) + 4(x+1)x(x-1) + (x+2)(x+1)x\big) = \frac{x}{6}\big(x^2 - 3x + 2 + 4x^2 - 4 + x^2 + 3x + 2\big) = \frac{x}{6}\big(6x^2\big) = x^3$.

3.1.6 RAMSEY NUMBERS

The Ramsey numbers arise from the work of Frank P. Ramsey (1903–1930), who in 1930 published a paper [Ra30] dealing with set theory that generalized the pigeonhole principle. (Also see §7.11.1, §8.11.2.) [GrRoSp13], [MiRo91], [RoTe09]

Definitions:

The ***Ramsey number*** $R(m,n)$ is the smallest positive integer k with the following property: if S is a set of size k and the 2-element subsets of S are partitioned into 2 collections, C_1 and C_2, then there is a subset of S of size m such that each of its 2-element subsets belong to C_1 or there is a subset of S of size n such that each of its 2-element sets belong to C_2.

The ***Ramsey number*** $R(m_1,\ldots,m_n;r)$ is the smallest positive integer k with the following property: if S is a set of size k and the r-element subsets of S are partitioned into n collections $C_1,\ldots,C_n$, then for some j there is a subset of S of size m_j such that each of its r-element subsets belong to C_j.

The ***Schur number*** $S(n)$ is the smallest integer k with the following property: if $\{1,\ldots,k\}$ is partitioned into n subsets $A_1,\ldots,A_n$, then there is a subset A_i such that the equation $x + y = z$ has a solution where $x,y,z \in A_i$. (Issai Schur, 1875–1941)

Facts:

1. *Ramsey's theorem*: The Ramsey numbers $R(m,n)$ and $R(m_1,\ldots,m_n;r)$ are well defined for all $m,n \geq 1$ and for all $m_1,\ldots,m_n \geq 1$, $r \geq 1$.

2. Ramsey numbers $R(m,n)$ can be phrased in terms of coloring edges of the complete graphs K_n: the Ramsey number $R(m,n)$ is the smallest positive integer k such that, if each edge of K_k is colored red or blue, then either the red subgraph contains a copy of K_m or else the blue subgraph contains a copy of K_n. (See §8.11.2.)

3. *Symmetry:* $R(m,n) = R(n,m)$.

4. $R(m,1) = R(1,m) = 1$ for every $m \geq 1$.

5. $R(m,2) = R(2,m) = m$ for every $m \geq 1$.

6. The values of few Ramsey numbers are known. What is currently known about Ramsey numbers $R(m,n)$, for $3 \leq m \leq 10$ and $3 \leq n \leq 10$, and bounds on other Ramsey numbers are displayed in Table 4. The entries in the body of this table are $R(m,n)$ $(m,n \leq 10)$ when known, or the best known range $r_1 \leq R(m,n) \leq r_2$ when not known. The Ramsey numbers $R(3,3)$, $R(3,4)$, $R(3,5)$, and $R(4,4)$ were found by A. M. Gleason and R. E. Greenwood in 1955; $R(3,6)$ was found by J. G. Kalbfleisch in 1966; $R(3,7)$

was found by J. E. Graver and J. Yackel in 1968; $R(3,8)$ was found by B. McKay and Z. Ke Min; $R(3,9)$ was found by C. M. Grinstead and S. M. Roberts in 1982; $R(4,5)$ was found by B. McKay and S. Radziszowski in 1993.

Table 4: Some classical Ramsey numbers.

$m \backslash n$	3	4	5	6	7	8	9	10
3	6	9	14	18	23	28	36	40-42
4	–	18	25	36-41	49-61	58-84	73-115	92-149
5	–	–	43-49	58-87	80-143	101-216	126-316	144-442
6	–	–	–	102-165	113-298	132-495	169-780	179-1,171
7	–	–	–	–	205-540	217-1,031	241-1,713	289-2,826
8	–	–	–	–	–	282-1,870	317-3,583	$\leq$ 6,090
9	–	–	–	–	–	–	565-6,588	581-12,677
10	–	–	–	–	–	–	–	798-23,556

Bounds for $R(m,n)$ for $m = 3$ and 4, with $11 \leq n \leq 15$:

$47 \leq R(3,11) \leq 50$	$98 \leq R(4,11) \leq 191$
$52 \leq R(3,12) \leq 59$	$128 \leq R(4,12) \leq 238$
$59 \leq R(3,13) \leq 68$	$133 \leq R(4,13) \leq 291$
$66 \leq R(3,14) \leq 77$	$141 \leq R(4,14) \leq 349$
$73 \leq R(3,15) \leq 87$	$153 \leq R(4,15) \leq 417$

7. If $m_1 \leq m_2$ and $n_1 \leq n_2$, then $R(m_1, n_1) \leq R(m_2, n_2)$.

8. $R(m,n) \leq R(m, n-1) + R(n-1, m)$ for all $m, n \geq 2$.

9. If $m \geq 3$, $n \geq 3$, and if $R(m, n-1)$ and $R(m-1, n)$ are even, then $R(m,n) \leq R(m, n-1) + R(m-1, n) - 1$.

10. $R(m,n) \leq \binom{m+n-2}{m-1}$. (Erdős and Szekeres, 1935)

11. The Ramsey numbers $R(m,n)$ satisfy the following asymptotic relationship:

$$\frac{\sqrt{2}}{e}(1 + o(1))m2^{m/2} \leq R(m,m) \leq \binom{2m+2}{m+1} \cdot O((\log m)^{-1}).$$

12. There exist constants c_1 and c_2 such that $c_1 m \ln m \leq R(3,m) \leq c_2 m \ln m$.

13. The problem of finding the Ramsey numbers $R(m_1, \ldots, m_n; 2)$ can be phrased in terms of coloring edges of the complete graphs K_n. $R(m_1, \ldots, m_n; 2)$ is equal to the smallest positive integer k with the following property: no matter how the edges of K_k are colored with the n colors $1, 2, \ldots, n$, there is some j such that K_k has a subgraph K_{m_j} of color j. (The edges of K_k are the 2-element subsets; C_j is the set of edges of color j.)

14. $R(m_1, m_2; 2) = R(m_1, m_2)$.

15. Very little is also known about the numbers $R(m_1, \ldots, m_n; 2)$ if $n \geq 3$.

16. $R(2, \ldots, 2; 2) = 2$.

17. If each $m_i \geq 3$, the only Ramsey number whose value is known is $R(3,3,3;2) = 17$.

18. $R(m, r, r, \ldots, r; r) = m$ if $m \geq r$.

19. $R(m_1, \ldots m_n; 1) = m_1 + \cdots + m_n - (n-1)$.

20. Ramsey theory is a generalization of the pigeonhole principle. In the terminology of Ramsey numbers, the fact that $R(2, \ldots, 2; 1) = n+1$ means that $n+1$ is the smallest positive integer with the property that if S has size $n+1$ and the subsets of S are partitioned into n sets $C_1, \ldots, C_n$, then for some j there is a subset of S of size 2 such that each of its elements belong to C_j. Hence, some C_j has at least two elements. If S is a set of $n+1$ pigeons and the subset C_j $(j = 1, \ldots, n)$ is the set of pigeons roosting in pigeonhole j, then some pigeonhole must have at least two pigeons in it. The Ramsey numbers $R(2, \ldots, 2; 1)$ give the smallest number of pigeons that force at least two to roost in the same pigeonhole.

21. *Schur's theorem*: $S(k) \leq R(3, \ldots, 3; 2)$ (where there are k 3s in the notation for the Ramsey number).

22. The following Schur numbers are known: $S(1) = 2$, $S(2) = 5$, $S(3) = 14$.

23. The equation $x + y = z$ in the definition of Schur numbers has been generalized to equations of the form $x_1 + \cdots + x_{n-1} = x_n$, $n \geq 4$. [BeBr82].

24. *Convex sets*: Ramsey numbers play a role in constructing convex polygons. Suppose m is a positive integer and there are n given points, no three of which are collinear. If $n \geq R(m, 5; 4)$, then a convex m-gon can be obtained from m of the n points [ErSz35]. This paper provided the impetus for the study of Ramsey numbers and suggested the possibility of its wide applicability in mathematics.

25. It remains an unsolved problem to find the smallest integer x (which depends on m) such that if $n \geq x$, then a convex m-gon can be obtained from m of the n points.

26. Extensive information on Ramsey number theory, including bounds on Ramsey numbers, can be found at S. Radziszowski's web site:

- `http://www.cs.rit.edu/~spr/ElJC/eline.html`

Examples:

1. If six people are at a party, then either three of these six are mutual friends or three are mutual strangers. If six is replaced by five, the result is not true. These facts follow since $R(3, 3) = 6$. (See Fact 2. The six people can be regarded as vertices, with a red edge joining friends and a blue edge joining strangers.)

2. If the set $\{1, \ldots, k\}$ is partitioned into two subsets A_1 and A_2, then the equation $x + y = z$ may or may not have a solution where $x, y, z \in A_1$ or $x, y, z \in A_2$. If $k \geq 5$, a solution is guaranteed since $S(2) = 5$. If $k < 5$, no solution is guaranteed—take $A_1 = \{1, 4\}$ and $A_2 = \{2, 3\}$.

3.1.7 OTHER SEQUENCES

Additional sequences that regularly arise in discrete mathematics are now described.

▷ Euler Polynomials

Definition:

The ***Euler polynomials*** $E_n(x)$ have the following exponential generating function: $\sum\limits_{n=0}^{\infty} E_n(x)\frac{t^n}{n!} = \frac{2e^{xt}}{e^t+1}$.

Facts:

1. $E_n(x+1) + E_n(x) = 2x^n$ for all $n \geq 0$.

2. The Euler polynomials can be expressed in terms of the Bernoulli numbers (§3.1.4): $E_{n-1}(x) = \frac{1}{n}\sum\limits_{k=1}^{n}(2 - 2^{k+1})\binom{n}{k}B_k x^{n-k}$ for all $n \geq 1$.

3. The alternating sum of powers of the first n integers can be expressed in terms of the Euler polynomials: $\sum\limits_{j=1}^{n}(-1)^{n-j}j^k = \frac{1}{2}\big[E_k(n+1)+(-1)^n E_k(0)\big]$.

4. The first 14 Euler polynomials $E_n(x)$ are shown in the following table.

n	$E_n(x)$
0	1
1	$x-\frac{1}{2}$
2	x^2-x
3	$x^3-\frac{3}{2}x^2+\frac{1}{4}$
4	x^4-2x^3+x
5	$x^5-\frac{5}{2}x^4+\frac{5}{2}x^2-\frac{1}{2}$
6	$x^6-3x^5+5x^3-3x$
7	$x^7-\frac{7}{2}x^6+\frac{35}{4}x^4-\frac{21}{2}x^2+\frac{17}{8}$
8	$x^8-4x^7+14x^5-28x^3+17x$
9	$x^9-\frac{9}{2}x^8+21x^6-63x^4+\frac{153}{2}x^2-\frac{31}{2}$
10	$x^{10}-5x^9+30x^7-126x^5+255x^3-155x$
11	$x^{11}-\frac{11}{2}x^{10}+\frac{165}{4}x^8-231x^6+\frac{2{,}805}{4}x^4-\frac{1{,}705}{2}x^2+\frac{691}{4}$
12	$x^{12}-6x^{11}+55x^9-396x^7+1{,}683x^5-3{,}410x^3+2{,}073x$
13	$x^{13}-\frac{13}{2}x^{12}+\frac{143}{2}x^{10}-\frac{1{,}287}{2}x^8+\frac{7{,}293}{2}x^6-\frac{22{,}165}{2}x^4+\frac{26{,}949}{2}x^2-\frac{5{,}461}{2}$

▷ Euler and Tangent Numbers

Definitions:

The ***Euler numbers*** E_n are given by $E_n = 2^n E_n(\frac{1}{2})$, where $E_n(x)$ is an Euler polynomial.

The ***tangent numbers*** T_n have the exponential generating function $\tan x$: $\sum\limits_{n=0}^{\infty} T_n \frac{x^n}{n!} = \tan x$.

Facts:

1. The first twelve Euler numbers E_n and tangent numbers T_n are shown in the following table.

n	0	1	2	3	4	5	6	7	8	9	10	11
E_n	1	0	−1	0	5	0	−61	0	1,385	0	−50,521	0
T_n	0	1	0	2	0	16	0	272	0	7,936	0	353,792

2. $E_{2k+1} = T_{2k} = 0$ for all $k \geq 0$.

3. The nonzero Euler numbers alternate in sign.

4. The Euler numbers have the exponential generating function $\frac{2}{e^t+e^{-t}} = \operatorname{sech} t$.

5. The exponential generating function for $|E_n|$ is $\sum_{n=0}^{\infty}|E_n|\frac{t^n}{n!} = \sec t$.

6. The tangent numbers can be expressed in terms of the Bernoulli numbers (§3.1.4): $T_{2n-1} = (-1)^{n-1}\frac{4^n(4^n-1)}{2n}B_{2n}$ for all $n \geq 1$.

7. The tangent numbers can be expressed as an alternating sum of Eulerian numbers (§3.1.5): $T_{2n+1} = \sum\limits_{k=0}^{2n}(-1)^{n-k}E(2n+1,k)$ for all $n \geq 0$.

8. $(-1)^n E_{2n}$ counts the number of *alternating* permutations in S_{2n}: that is, the number of permutations $\pi = (\pi_1, \pi_2, \ldots, \pi_{2n})$ on $\{1, 2, \ldots, 2n\}$ with $\pi_1 > \pi_2 < \pi_3 > \pi_4 < \cdots > \pi_{2n}$.

9. T_{2n+1} counts the number of alternating permutations in S_{2n+1}.

Examples:

1. The permutation $\pi = (\pi_1, \pi_2, \pi_3, \pi_4) = (2, 1, 4, 3)$ is alternating since $2 > 1 < 4 > 3$. In all there are $(-1)^2 E_4 = 5$ alternating permutations in S_4: $(2,1,4,3)$, $(3,1,4,2)$, $(3,2,4,1)$, $(4,1,3,2)$, $(4,2,3,1)$.

2. The permutation $\pi = (\pi_1, \pi_2, \pi_3, \pi_4, \pi_5) = (4, 1, 3, 2, 5)$ is alternating since $4 > 1 < 3 > 2 < 5$. In all there are $T_5 = 16$ alternating permutations in S_5.

▷ Harmonic Numbers

Definition:

The ***harmonic numbers*** H_n are given by $H_n = \sum_{i=1}^{n} \frac{1}{i}$ for $n \geq 0$, with $H_0 = 0$.

Facts:

1. H_n is the discrete analogue of the natural logarithm (§3.4.1).

2. The first twelve harmonic numbers H_n are shown in the following table.

n	0	1	2	3	4	5	6	7	8	9	10	11
H_n	0	1	$\frac{3}{2}$	$\frac{11}{6}$	$\frac{25}{12}$	$\frac{137}{60}$	$\frac{49}{20}$	$\frac{363}{140}$	$\frac{761}{280}$	$\frac{7{,}129}{2{,}520}$	$\frac{7{,}381}{2{,}520}$	$\frac{83{,}711}{27{,}720}$

3. The harmonic numbers can be expressed in terms of the Stirling cycle numbers (§2.5.2): $H_n = \frac{1}{n!}\left[{n+1 \atop 2}\right]$, $n \geq 1$.

4. $\sum\limits_{i=1}^{n} H_i = (n+1)\big[H_{n+1} - 1\big]$ for all $n \geq 1$.

5. $\sum\limits_{i=1}^{n} iH_i = \binom{n+1}{2}\big[H_{n+1} - \frac{1}{2}\big]$ for all $n \geq 1$.

6. $\sum\limits_{i=1}^{n} \binom{i}{k} H_i = \binom{n+1}{k+1}\big[H_{n+1} - \frac{1}{k+1}\big]$ for all $n \geq 1$.

7. $H_n \to \infty$ as $n \to \infty$.

8. $H_n \sim \ln n + \gamma + \frac{1}{2n} - \frac{1}{12n^2} + \frac{1}{120n^4}$, where $\gamma \approx 0.577215664901533$ denotes Euler's constant.

9. The harmonic numbers have the generating function $\frac{1}{1-x} \ln \frac{1}{1-x}$.

Example:

1. Fact 8 yields the approximation $H_{10} \approx 2.928968257896$. The actual value is $H_{10} = 2.928968253968\ldots$, so the approximation is accurate to 9 significant digits. The approximation $H_{20} \approx 3.597739657206$ is accurate to 10 digits, and the approximation $H_{40} \approx 4.27854303893$ is accurate to 12 digits.

▷ Gray Codes

Definition:

A ***Gray code*** of size n is an ordering $G^n = (g_1, g_2, \ldots, g_{2^n})$ of the 2^n binary strings of length n such that g_k and g_{k+1} differ in exactly one bit, for $1 \leq k < 2^n$. Usually it is required that g_{2^n} and g_1 also differ in exactly one bit.

Facts:

1. Gray codes exist for all $n \geq 1$. Sample Gray codes G^n are shown in the following table.

n	G^n								
1	0	1							
2	00	10	11	01					
3	000	100	110	010	011	111	101	001	
4	0000	1000	1100	0100	0110	1110	1010	0010	0011
	1011	1111	0111	0101	1101	1001	0001		
5	00000	10000	11000	01000	01100	11100	10100	00100	00110
	10110	11110	01110	01010	11010	10010	00010	00011	10011
	11011	01011	01111	11111	10111	00111	00101	10101	11101
	01101	01001	11001	10001	00001				

2. A Gray code of size $n \geq 2$ corresponds to a Hamilton cycle in the n-cube (§8.4.4).

3. Gray codes correspond to an ordering of all subsets of $\{1, 2, \ldots, n\}$ such that adjacent subsets differ by the insertion or deletion of exactly one element. Each subset A corresponds to a binary string $a_1 a_2 \ldots a_n$ where $a_i = 1$ if $i \in A$, $a_i = 0$ if $i \notin A$.

4. A Gray code G^n can be recursively obtained in the following way:

- *first half of G^n*: Add a 0 to the end of each string in G^{n-1}.
- *second half of G^n*: Add a 1 to the end of each string in the reversal of G^{n-1}.

▷ de Bruijn Sequences

Definitions:

A ***(p, n) de Bruijn sequence*** on the alphabet $\Sigma = \{0, 1, \ldots, p-1\}$ is a sequence $(s_0, s_1, \ldots, s_{L-1})$ of $L = p^n$ elements $s_i \in \Sigma$ such that each consecutive subsequence $(s_i, s_{i+1}, \ldots, s_{i+n-1})$ of length n is distinct. Here the addition of subscripts is done modulo L so that the sequence is considered as a circular ordering. (Nicolaas G. de Bruijn, 1918–2012)

The ***de Bruijn diagram*** $D_{p,n}$ is a directed graph whose vertices correspond to all possible strings $s_1 s_2 \ldots s_{n-1}$ of $n-1$ symbols from Σ. There are p arcs leaving the vertex $s_1 s_2 \ldots s_{n-1}$, each labeled with a distinct symbol $\alpha \in \Sigma$ and leading to the adjacent vertex $s_2 s_3 \ldots s_{n-1}\alpha$.

Facts:

1. The de Bruijn diagram $D_{p,n}$ has p^{n-1} vertices and p^n arcs.

2. $D_{p,n}$ is a strongly connected digraph (§8.3.2).

3. $D_{p,n}$ is an Eulerian digraph (§8.4.3).

4. There are $(p!)^{p^{n-1}} p^{-n}$ distinct (p, n) de Bruijn sequences.

5. Any Euler circuit in $D_{p,n}$ produces a (p, n) de Bruijn sequence.

6. de Bruijn sequences exist for all p (with $n \geq 1$). Sample de Bruijn sequences are shown in the following table.

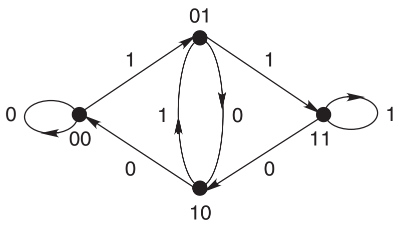
(p,n)	*de Bruijn sequence*
$(2,1)$	01
$(2,2)$	0110
$(2,3)$	01110100
$(2,4)$	0101001101111000
$(3,2)$	012202110
$(3,3)$	012001110100022212202112102
$(4,2)$	0113102212033230

7. A de Bruijn sequence can be generated from an alphabet $\Sigma = \{0, 1, \ldots, p-1\}$ of p symbols using Algorithm 1.

```
Algorithm 1: Generating a $(p, n)$ de Bruijn sequence.
  1. Start with the sequence $S$ containing $n$ zeros.
  2. Append the largest symbol from $\Sigma$ to $S$ so that the newly formed sequence
     $S'$ of $n$ symbols does not already appear as a subsequence of $S$. Let $S = S'$.
  3. Repeat Step 2 as long as possible.
  4. When Step 2 cannot be applied, remove the last $n-1$ symbols from $S$.
```

Examples:

1. The de Bruijn diagram $D_{2,3}$ is shown in the following figure. An Eulerian circuit is obtained by visiting in order the vertices $11, 10, 01, 10, 00, 00, 01, 11, 11$. The de Bruijn sequence 01000111 is obtained by reading off the edge labels α as this circuit is traversed.



2. When $p = 2$ and $n = 3$, the formula in Fact 4 gives

$$\frac{(2!)^{2^{3-1}}}{2^3} = \frac{2^4}{2^3} = 2$$

distinct (2,3) de Bruijn sequences. These are 01000111 and its reversal 11100010.

▷ Self-generating Sequences

Definition:

Some unusual sequences defined by simple recurrence relations or rules are informally called ***self-generating sequences***.

Examples:

1. *Hofstadter G-sequence*: This sequence is defined by $a(n) = n - a(a(n-1))$, with initial condition $a(0) = 0$. The initial terms of this sequence are 0, 1, 1, 2, 3, 3, 4, 4, 5, 6, 7, 8, 8, 9, 9, 10, ... It is easy to show this sequence is well defined. A formula for the nth term of this sequence is $a(n) = \lfloor (n+1)\mu \rfloor$, where $\mu = (-1+\sqrt{5})/2$. [Ho79]

2. *Variations of the Hofstadter G-sequence about which little is known*: These include the sequence defined by $a(n) = n - a(a(a(n-1)))$ with $a(0) = 1$, whose initial terms are $0, 1, 1, 2, 3, 4, 4, 5, 5, 6, 7, 7, 8, 9, 10, 10, 11, 12, 13, \ldots$ and the sequence defined by $a(n) = n - a(a(a(a(n-1)))$ with $a(0) = 1$, whose initial terms are 0, 1, 1, 2, 3, 4, 5, 5, 6, 6, 7, 8, 8, 9, 10, 11, 11, 12, 13, 14, ...

3. The sequence $a(n) = a(n - a(n-1)) + a(n - a(n-2))$, with $a(0) = a(1) = 1$, was also defined by Hofstadter. The initial terms of this sequence are 1, 1, 2, 3, 3, 4, 5, 5, 6, 6, 6, 8, 8, 8, 10, 10, 10, 12, ...

4. The intertwined sequence $F(n)$ and $M(n)$ are defined by $F(n) = n - F(M(n-1))$ and $M(n) = n - M(F(n-1))$, with initial conditions $F(0) = 1$ and $M(0) = 0$. The initial terms of the sequence $F(n)$ (sometimes called the "female" sequence of the pair) begins with the terms $1, 1, 2, 2, 3, 3, 4, 5, 5, 6, 6, 7, 8, 8, 9, 9, 10, \ldots$ and the initial terms of the sequence $M(n)$ (sometimes called the "male" sequence of the pair) begins with the terms $0, 0, 1, 2, 2, 3, 4, 4, 5, 6, 6, 7, 7, 8, 9, 9, 10, \ldots$.

5. *Golomb's self-generating sequence*: This sequence is the unique nondecreasing sequence $a_1, a_2, a_3, \ldots$ with the property that it contains exactly a_k occurrences of the integer k for each integer k. The initial terms of this sequence are 1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, 6, 6, 6, 6, ...

6. If $f(n)$ is the largest integer m such that $a_m = n$ where a_k is the kth term of Golomb's self-generating sequence, then $f(n) = \sum_{k=1}^{n} a_k$ and $f(f(n)) = \sum_{k=1}^{n} ka_k$.

3.1.8 MINIGUIDE TO SEQUENCES

This section lists the numerical values of various integer sequences, classified according to the type of combinatorial structure that produces the terms. This listing supplements many of the tables presented in this *Handbook*. A tabulation of over 5,400 integer sequences is provided in [SlPl95], and over 250,000 entries are available through an online database. (See Fact 4.)

Definitions:

The ***power sum*** $S^k(n) = \sum_{j=1}^{n} j^k$ is the sum of the kth powers of the first n positive integers. The sum of the kth powers of the first n odd integers is denoted $O^k(n) = \sum_{j=1}^{n}(2j-1)^k$.

The ***associated Stirling number of the first kind*** $d(n,k)$ is the number of k-cycle permutations of an n-element set with all cycles of length ≥ 2.

The ***associated Stirling number of the second kind*** $b(n,k)$ is the number of k-block partitions of an n-element set with all blocks of size ≥ 2.

The ***double factorial*** $n!!$ is the product $n(n-2)\ldots 6 \cdot 4 \cdot 2$ if n is an even positive integer and $n(n-2)\ldots 5 \cdot 3 \cdot 1$ if n is an odd positive integer.

The ***Lah coefficients*** $L(n,k)$ are the coefficients of $x^{\underline{k}}$ (§3.4.2) resulting from the expansion of $x^{\overline{n}}$ (§3.4.2):

$$x^{\overline{n}} = \sum_{k=1}^{n} L(n,k)x^{\underline{k}}.$$

A permutation π is ***discordant*** from a set A of permutations when $\pi(i) \neq \alpha(i)$ for all i and all $\alpha \in A$. Usually A consists of the identity permutation ι and powers of the n-cycle $\sigma_n = (1\ 2\ \ldots\ n)$ (see §5.3.1).

A ***necklace*** with n beads in c colors corresponds to an equivalence class of functions from an n-set to a c-set, under cyclic or dihedral equivalence.

A ***figurate number*** is the number of cells in an array of cells bounded by some regular geometrical figure.

A ***polyomino*** with p polygons (cells) is a connected configuration of p regular polygons in the plane. The polygons usually considered are either triangles, squares, or hexagons.

Facts:

1. A database of integer sequences was initiated by Neal J. A. Sloane in 1964, while he was exploring the sequence 1, 8, 78, 944, . . . that arose in determining the average height of vertices in rooted trees.

2. Sloane published the book [Sl73], which contained over 2,300 integer sequences.

3. Together with Simon Plouffe, Sloane published a revised and expanded version of the book in 1995 [SlPl95]; it contained over 5,400 integer sequences.

4. *World Wide Web page*: Sequences can be accessed and identified using a web page maintained by The OEIS Foundation:

- `http://oeis.org`

Sequences are arranged in lexicographic order, after ignoring any initial 0 or 1 terms as well as the signs of terms, and are uniquely identified as A plus six digits.

5. Each entry in the following miniguide lists initial terms of the sequence, provides a brief description, and gives the reference number used in the online database of Fact 4.

Examples:

1. The initial five terms `1,2,6,20,70,252` of an unknown sequence were entered at the site listed in Fact 4. Several matching sequences were identified, the first of which (A000984) corresponds to the central binomial coefficients $\binom{2n}{n}$. Entering the terms above, separated by commas, identifies sequences in which the specified numbers occur consecutively in the order given.

2. Entering the initial terms `1 1 2 3 5 8 13 21 34` into the OEIS site produced over 10,000 matching sequences. In this case, spaces were used rather than commas to delimit the terms and so sequences matching the given terms in any order are returned. The first sequence produced was the Fibonacci sequence (A000045); another was the sequence $a_n = \lceil e^{\frac{n-1}{2}} \rceil$ (A005181).

▷ Miniguide to Sequences from Discrete Mathematics

The following miniguide contains a selection of important sequences, grouped by functional problem area (such as graph theory, algebra, number theory). The sequences are listed in a logical, rather than lexicographic, order within each identifiable grouping. This listing supplements existing tables within the *Handbook*. References to appropriate sections of the *Handbook* are also provided. The notation "A*xxxxxx*" is the reference number used in the OEIS database (Fact 4).

$\boldsymbol{L(n, 6)}$ [A001778]

Eulerian Numbers (§3.1.5)

$1, 4, 11, 26, 57, 120, 247, 502, 1013, 2036, 4083, 8178, 16369, 32752, 65519, 131054, 262125$
$\boldsymbol{E(n, 1)}$ [A000295]

$1, 11, 66, 302, 1191, 4293, 14608, 47840, 152637, 478271, 1479726, 4537314, 13824739$
$\boldsymbol{E(n, 2)}$ [A000460]

$1, 26, 302, 2416, 15619, 88234, 455192, 2203488, 10187685, 45533450, 198410786$
$\boldsymbol{E(n, 3)}$ [A000498]

$1, 57, 1191, 15619, 156190, 1310354, 9738114, 66318474, 423281535, 2571742175$
$\boldsymbol{E(n, 4)}$ [A000505]

$1, 120, 4293, 88234, 1310354, 15724248, 162512286, 1505621508, 12843262863$
$\boldsymbol{E(n, 5)}$ [A000514]

$1, 247, 14608, 455192, 9738114, 162512286, 2275172004, 27971176092, 311387598411$
$\boldsymbol{E(n, 6)}$ [A001243]

$1, 502, 47840, 2203488, 66318474, 1505621508, 27971176092, 447538817472, 6382798925475$
$\boldsymbol{E(n, 7)}$ [A001244]

Other Special Sequences (§3.1)

$1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181, 6795, 10946, 17711$
Fibonacci numbers, $\boldsymbol{n \geq 1}$ [A000045]

$1, 3, 4, 7, 11, 18, 29, 47, 76, 123, 199, 322, 521, 843, 1364, 2207, 3571, 5778, 9349, 15127$
Lucas numbers, $\boldsymbol{n \geq 1}$ [A000204]

$1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, 208012, 742900, 2674440, 9694845$
Catalan numbers, $\boldsymbol{n \geq 0}$ [A000108]

$1, 3, 11, 25, 137, 49, 363, 761, 7129, 7381, 83711, 86021, 1145993, 1171733, 1195757$
numerators of harmonic numbers, $\boldsymbol{n \geq 1}$ [A001008]

1, 2, 6, 12, 60, 20, 140, 280, 2520, 2520, 27720, 27720, 360360, 360360, 360360, 720720
denominators of harmonic numbers, $n \geq 1$ [A002805]

1, 1, 1, 1, 1, 5, 691, 7, 3617, 43867, 174611, 854513, 236364091, 8553103, 23749461029
numerators of Bernoulli numbers $|B_{2n}|$, $n \geq 0$ [A000367]

1, 6, 30, 42, 30, 66, 2730, 6, 510, 798, 330, 138, 2730, 6, 870, 14322, 510, 6, 1919190, 6, 13530
denominators of Bernoulli numbers $|B_{2n}|$, $n \geq 0$ [A002445]

1, 1, 5, 61, 1385, 50521, 2702765, 199360981, 19391512145, 2404879675441
Euler numbers $|E_{2n}|$, $n \geq 0$ [A000364]

1, 2, 16, 272, 7936, 353792, 22368256, 1903757312, 209865342976, 29088885112832
tangent numbers T_{2n+1}, $n \geq 0$ [A000182]

1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, 115975, 678570, 4213597, 27644437, 190899322
Bell numbers, $n \geq 0$ [A000110]

Numbers of Certain Algebraic Structures (§1.4, §5.2)

1, 1, 1, 2, 1, 1, 1, 3, 2, 1, 1, 2, 1, 1, 1, 5, 1, 2, 1, 2, 1, 1, 1, 3, 2, 1, 3, 2, 1, 1, 1, 7, 1, 1, 1, 4, 1, 1, 1, 3
abelian groups of order n [A000688]

1, 1, 1, 2, 1, 2, 1, 5, 2, 2, 1, 5, 1, 2, 1, 14, 1, 5, 1, 5, 2, 2, 1, 15, 2, 2, 5, 4, 1, 4, 1, 51, 1, 2, 1, 14, 1, 2
groups of order n [A000001]

2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 60, 61, 67, 71, 73, 79, 83, 89, 97, 101
orders of simple groups [A005180]

60, 168, 360, 504, 660, 1092, 2448, 2520, 3420, 4080, 5616, 6048, 6072, 7800, 7920, 9828
orders of noncyclic simple groups [A001034]

1, 1, 2, 5, 16, 63, 318, 2045, 16999, 183231, 2567284, 46749427, 1104891746, 33823827452
partially ordered sets on n elements [A000112]

1, 2, 13, 171, 3994, 154303, 9415189, 878222530, 122207703623, 24890747921947
transitive relations on n elements [A006905]

1, 5, 52, 1522, 145984, 48464496, 56141454464, 229148550030864, 3333310786076963968
relations on n unlabeled points [A001173]

1, 2, 1, 2, 3, 6, 9, 18, 30, 56, 99, 186, 335, 630, 1161, 2182, 4080, 7710, 14532, 27594, 52377
binary irreducible polynomials of degree n [A001037]

Permutations (§5.3.1)

by cycles

1, 1, 1, 3, 15, 75, 435, 3045, 24465, 220185, 2200905, 24209955, 290529855, 3776888115
no 2-cycles [A000266]

1, 1, 2, 4, 16, 80, 520, 3640, 29120, 259840, 2598400, 28582400, 343235200, 4462057600
no 3-cycles [A000090]

1, 1, 2, 6, 18, 90, 540, 3780, 31500, 283500, 2835000, 31185000, 372972600, 4848643800
no 4-cycles [A000138]

0, 1, 1, 3, 9, 45, 225, 1575, 11025, 99225, 893025, 9823275, 108056025, 1404728325
no even length cycles [A000246]

discordant (§2.4.2, §3.1.8)

1, 0, 1, 2, 9, 44, 265, 1854, 14833, 133496, 1334961, 14684570, 176214841, 2290792932
derangements, discordant for ι [A000166]

1, 1, 0, 1, 2, 13, 80, 579, 4738, 43387, 439792, 4890741, 59216642, 775596313, 10927434464
menage numbers, discordant for ι and σ_n [A000179]

0, 1, 2, 20, 144, 1265, 12072, 126565, 1445100, 17875140, 238282730, 3407118041
discordant for $\iota, \sigma_n, \sigma_n^2$ [A000183]

by order
1, 2, 3, 4, 6, 6, 12, 15, 20, 30, 30, 60, 60, 84, 105, 140, 210, 210, 420, 420, 420, 420, 840, 840
max order [A000793]

1, 2, 3, 4, 6, 12, 15, 20, 30, 60, 84, 105, 140, 210, 420, 840, 1260, 1540, 2310, 2520, 4620, 5460
max order, increasing [A002809]

1, 2, 4, 16, 56, 256, 1072, 11264, 78976, 672256, 4653056, 49810432, 433429504, 4448608256
order a power of 2 [A005388]

0, 1, 3, 9, 25, 75, 231, 763, 2619, 9495, 35695, 140151, 568503, 2390479, 10349535, 46206735
order 2 [A001189]

0, 0, 2, 8, 20, 80, 350, 1232, 5768, 31040, 142010, 776600, 4874012, 27027728, 168369110
order 3 [A001471]

0, 0, 0, 6, 30, 180, 840, 5460, 30996, 209160, 1290960, 9753480, 69618120, 571627056
order 4 [A001473]

0, 0, 1, 3, 6, 10, 30, 126, 448, 1296, 4140, 17380, 76296, 296088, 1126216, 4940040, 23904000
odd, order 2 [A001465]

Necklaces (§2.6)
1, 2, 3, 4, 6, 8, 14, 20, 36, 60, 108, 188, 352, 632, 1182, 2192, 4116, 7712, 14602, 27596, 52488
2 colors, n beads [A000031]

1, 3, 6, 11, 24, 51, 130, 315, 834, 2195, 5934, 16107, 44368, 122643, 341802, 956635, 2690844
3 colors, n beads [A001867]

1, 4, 10, 24, 70, 208, 700, 2344, 8230, 29144, 104968, 381304, 1398500, 5162224, 19175140
4 colors, n beads [A001868]

1, 5, 15, 45, 165, 629, 2635, 11165, 48915, 217045, 976887, 4438925, 20346485, 93900245
5 colors, n beads [A001869]

Number Theory (§4.4, §4.6)
2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103
primes [A000040]

0, 1, 2, 2, 3, 3, 4, 4, 4, 4, 5, 5, 6, 6, 6, 6, 7, 7, 8, 8, 8, 8, 9, 9, 9, 9, 9, 9, 10, 10, 11, 11, 11, 11, 11, 11
number of primes $\le n$ [A000720]

1, 1, 1, 1, 1, 2, 1, 1, 1, 2, 1, 2, 1, 2, 2, 1, 1, 2, 1, 2, 2, 2, 1, 2, 1, 2, 1, 2, 1, 3, 1, 1, 2, 2, 2, 2, 1, 2, 2, 2
number of distinct primes dividing n [A001221]

2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 9689
Mersenne primes [A000043]

1, 1, 1, 2, 1, 2, 1, 3, 2, 2, 1, 4, 1, 2, 2, 5, 1, 4, 1, 4, 2, 2, 1, 7, 2, 2, 3, 4, 1, 5, 1, 7, 2, 2, 2, 9, 1, 2, 2, 7
number of ways of factoring n [A001055]

1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4, 12, 6, 8, 8, 16, 6, 18, 8, 12, 10, 22, 8, 20, 12, 18, 12, 28, 8, 30, 16
Euler totient function [A000010]

561, 1105, 1729, 2465, 2821, 6601, 8911, 10585, 15841, 29341, 41041, 46657, 52633, 62745
Carmichael numbers [A002997]

1, 2, 2, 3, 2, 4, 2, 4, 3, 4, 2, 6, 2, 4, 4, 5, 2, 6, 2, 6, 4, 4, 2, 8, 3, 4, 4, 6, 2, 8, 2, 6, 4, 4, 4, 9, 2, 4, 4, 8
number of divisors of n [A000005]

1, 3, 4, 7, 6, 12, 8, 15, 13, 18, 12, 28, 14, 24, 24, 31, 18, 39, 20, 42, 32, 36, 24, 60, 31, 42, 40, 56
sum of divisors of *n* [A000203]

6, 28, 496, 8128, 33550336, 8589869056, 137438691328, 2305843008139952128
perfect numbers [A000396]

Partitions (§2.5.1)

1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56, 77, 101, 135, 176, 231, 297, 385, 490, 627, 792, 1002, 1255
partitions of *n* [A000041]

1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18, 22, 27, 32, 38, 46, 54, 64, 76, 89, 104, 122, 142, 165, 192
partitions of *n* into distinct parts [A000009]

1, 3, 6, 13, 24, 48, 86, 160, 282, 500, 859, 1479, 2485, 4167, 6879, 11297, 18334, 29601, 47330
planar partitions of *n* [A000219]

Figurate Numbers (§3.1.8)

polygonal

1, 3, 6, 10, 15, 21, 28, 36, 45, 55, 66, 78, 91, 105, 120, 136, 153, 171, 190, 210, 231, 253, 276
triangular [A000217]

1, 5, 12, 22, 35, 51, 70, 92, 117, 145, 176, 210, 247, 287, 330, 376, 425, 477, 532, 590, 651, 715
pentagonal [A000326]

1, 6, 15, 28, 45, 66, 91, 120, 153, 190, 231, 276, 325, 378, 435, 496, 561, 630, 703, 780, 861, 946
hexagonal [A000384]

1, 7, 18, 34, 55, 81, 112, 148, 189, 235, 286, 342, 403, 469, 540, 616, 697, 783, 874, 970, 1071
heptagonal [A000566]

3.2 GENERATING FUNCTIONS

Generating functions express an infinite sequence as coefficients arising from a power series in an auxiliary variable. The closed form of a generating function is a concise way to represent such an infinite sequence. Properties of the sequence can be explored by analyzing the closed form of an associated generating function. Two types of generating functions are discussed in this section—ordinary generating functions and exponential generating functions. The former arise when counting configurations in which order is not important, while the latter are appropriate when order matters.

3.2.1 ORDINARY GENERATING FUNCTIONS

Definitions:

The (***ordinary***) ***generating function*** for the sequence $a_0, a_1, a_2, \ldots$ of real numbers is the formal power series $f(x) = a_0 + a_1x + a_2x^2 + \cdots = \sum_{i=0}^{\infty} a_ix^i$ or any equivalent closed form expression.

The ***convolution*** of the sequence $a_0, a_1, a_2, \ldots$ and the sequence $b_0, b_1, b_2, \ldots$ is the sequence $c_0, c_1, c_2, \ldots$ in which $c_t = a_0b_t + a_1b_{t-1} + a_2b_{t-2} + \cdots + a_tb_0 = \sum_{k=0}^{t} a_kb_{t-k}$.

Facts:

1. Generating functions are considered as algebraic forms and can be manipulated as such, without regard to actual convergence of the power series.

2. A rational form (the ratio of two polynomials) is a concise expression for the generating function of the sequence obtained by carrying out long division on the polynomials. (See Example 1.)

3. Generating functions are often useful for constructing and verifying identities involving binomial coefficients and other special sequences. (See Example 10.)

4. Generating functions can be used to derive formulas for the sums of powers of integers. (See Example 17.)

5. Generating functions can be used to solve recurrence relations. (See §3.3.4.)

6. Each sequence $\{a_n\}$ defines a *unique* generating function $f(x)$, and conversely.

7. *Related generating functions*: Suppose $f(x) = \sum_{k=0}^{\infty} a_kx^k$ and $g(x) = \sum_{k=0}^{\infty} b_kx^k$ are generating functions for the sequences $a_0, a_1, a_2, \ldots$ and $b_0, b_1, b_2, \ldots$, respectively. Table 1 gives some related generating functions.

Table 1: Related generating functions.

generating function	*sequence*
$x^nf(x)$	$\underbrace{0, 0, 0, \ldots, 0}_{n}, a_0, a_1, a_2, \ldots$

generating function	*sequence*
$f(x) - a_n x^n$	$a_0, a_1, \ldots, a_{n-1}, 0, a_{n+1}, \ldots$
$a_0 + a_1 x + \cdots + a_n x^n$	$a_0, a_1, \ldots, a_n, 0, 0, \ldots$
$f(x^2)$	$a_0, 0, a_1, 0, a_2, 0, a_3, \ldots$
$\frac{f(x)-a_0}{x}$	$a_1, a_2, a_3, \ldots$
$\frac{f(x)-a_0-a_1x-\cdots-a_nx^n}{x^{n+1}}$	$a_{n+1}, a_{n+2}, a_{n+3}, \ldots$
$f'(x)$	$a_1, 2a_2, 3a_3, \ldots, ka_k, \ldots$
$xf'(x)$	$0, a_1, 2a_2, 3a_3, \ldots, ka_k, \ldots$
$\int_0^x f(t)\,dt$	$0, a_0, \frac{a_1}{2}, \frac{a_2}{3}, \ldots, \frac{a_k}{k+1}, \ldots$
$\frac{f(x)}{1-x}$	$a_0, a_0 + a_1, a_0 + a_1 + a_2, a_0 + a_1 + a_2 + a_3, \ldots$
$(1+x)f(x)$	$a_0, a_0 + a_1, a_1 + a_2, \ldots, a_k + a_{k+1}, \ldots$
$(1+x+x^2)f(x)$	$a_0, a_0 + a_1, a_0 + a_1 + a_2, a_1 + a_2 + a_3, \ldots$
$rf(x) + sg(x)$	$ra_0 + sb_0, ra_1 + sb_1, ra_2 + sb_2, \ldots$
$f(x)g(x)$	$a_0b_0, a_0b_1 + a_1b_0, a_0b_2 + a_1b_1 + a_2b_0, \ldots$ (the convolution of $\{a_n\}$ and $\{b_n\}$)

Examples:

1. The sequence $0, 1, 4, 9, 16, \ldots$ of squares of the nonnegative integers has the generating function $0 + x + 4x^2 + 9x^3 + 16x^4 + \cdots$. However, this generating function has a concise closed form expression, namely $\frac{x+x^2}{1-3x+3x^2-x^3}$. Verification is obtained by carrying out long division on the indicated polynomials. This concise form can be used to deduce properties involving the sequence, such as an explicit algebraic expression for the sum of squares of the first n positive integers. (See Example 17.)

2. The generating function for the sequence $1, 1, 1, 1, 1, \ldots$ is $1 + x + x^2 + x^3 + x^4 + \cdots = \frac{1}{1-x}$. Differentiating both sides of this expression produces $1+2x+3x^2+4x^3+\cdots = \frac{1}{(1-x)^2}$. Thus, $\frac{1}{(1-x)^2}$ is a closed form expression for the generating function of the sequence $1, 2, 3, 4, \ldots$. (See Table 2.)

3. Table 2 gives closed form expressions for the generating functions of particular sequences. In this table, r is an arbitrary real number, F_n is the nth Fibonacci number (§3.1.2), L_n is the nth Lucas number (§3.1.2), C_n is the nth Catalan number (§3.1.3), and H_n is the nth harmonic number (§3.1.7).

Table 2: Generating functions for particular sequences.

sequence	*closed form*
$1, 1, 1, 1, 1, \ldots$	$\frac{1}{1-x}$
$1, 1, \ldots, 1, 0, 0, \ldots$ (n 1s)	$\frac{1-x^n}{1-x}$
$1, 1, \ldots, 1, 1, 0, 1, 1, \ldots$ (0 following n 1s)	$\frac{1}{1-x} - x^n$
$1, -1, 1, -1, 1, -1, \ldots$	$\frac{1}{1+x}$
$1, 0, 1, 0, 1, \ldots$	$\frac{1}{1-x^2}$
$1, 2, 3, 4, 5, \ldots$	$\frac{1}{(1-x)^2}$
$1, 4, 9, 16, 25, \ldots$	$\frac{1+x}{(1-x)^3}$
$1, r, r^2, r^3, r^4, \ldots$	$\frac{1}{1-rx}$
$0, r, 2r^2, 3r^3, 4r^4, \ldots$	$\frac{rx}{(1-rx)^2}$

sequence	*closed form*
$0, 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \ldots$	$\ln \frac{1}{1-x}$
$\frac{1}{0!}, \frac{1}{1!}, \frac{1}{2!}, \frac{1}{3!}, \frac{1}{4!}, \ldots$	e^x
$0, 1, -\frac{1}{2}, \frac{1}{3}, -\frac{1}{4}, \frac{1}{5}, \ldots$	$\ln(1+x)$
$F_0, F_1, F_2, F_3, F_4, \ldots$	$\frac{x}{1-x-x^2}$
$L_0, L_1, L_2, L_3, L_4, \ldots$	$\frac{2-x}{1-x-x^2}$
$C_0, C_1, C_2, C_3, C_4, \ldots$	$\frac{1-\sqrt{1-4x}}{2x}$
$H_0, H_1, H_2, H_3, H_4, \ldots$	$\frac{1}{1-x} \ln \frac{1}{1-x}$

4. For every positive integer n, the binomial theorem (§2.3.4) states that

$$(1+x)^n = \binom{n}{0} + \binom{n}{1}x + \binom{n}{2}x^2 + \cdots + \binom{n}{n}x^n = \sum_{k=0}^{n} \binom{n}{k}x^k,$$

so $(1+x)^n$ is a closed form for the generating function of $\binom{n}{0}, \binom{n}{1}, \binom{n}{2}, \ldots, \binom{n}{n}, 0, 0, 0, \ldots$.

5. For every positive integer n, the Maclaurin series expansion for $(1+x)^{-n}$ is

$$\begin{aligned}(1+x)^{-n} &= 1 + (-n)x + \tfrac{(-n)(-n-1)x^2}{2!} + \cdots \\ &= 1 + \sum_{k=1}^{\infty} \tfrac{(-n)(-n-1)(-n-2)\ldots(-n-k+1)}{k!}x^k.\end{aligned}$$

Consequently, $(1+x)^{-n}$ is the generating function for the sequence $\binom{-n}{0}, \binom{-n}{1}, \binom{-n}{2}, \ldots$, where $\binom{-n}{k} = (-1)^k\binom{n+k-1}{k}$ is an extended binomial coefficient (§2.3.2).

6. Using Example 5, the expansion of $f(x) = (1-3x)^{-8}$ is

$$(1-3x)^{-8} = (1+y)^{-8} = \sum_{k=0}^{\infty} \binom{-8}{k}y^k = \sum_{k=0}^{\infty} \binom{-8}{k}(-3x)^k.$$

So the coefficient of x^4 in $f(x)$ is $\binom{-8}{4}(-3)^4 = (-1)^4\binom{8+4-1}{4}(81) = \binom{11}{4}(81) = 26{,}730$.

7. Table 3 gives additional examples of generating functions related to binomial expansions. In this table, m and n are positive integers, and r is any real number.

Table 3: Examples of binomial-type generating functions.

generating function	*expansion*
$(1+x)^n$	$\binom{n}{0} + \binom{n}{1}x + \binom{n}{2}x^2 + \cdots + \binom{n}{n}x^n = \sum_{k=0}^{n} \binom{n}{k}x^k$
$(1+rx)^n$	$\binom{n}{0} + \binom{n}{1}rx + \binom{n}{2}r^2x^2 + \cdots + \binom{n}{n}r^nx^n = \sum_{k=0}^{n} \binom{n}{k}r^kx^k$
$(1+x^m)^n$	$\binom{n}{0} + \binom{n}{1}x^m + \binom{n}{2}x^{2m} + \cdots + \binom{n}{n}x^{nm} = \sum_{k=0}^{n} \binom{n}{k}x^{km}$
$(1+x)^{-n}$	$\binom{-n}{0} + \binom{-n}{1}x + \binom{-n}{2}x^2 + \cdots = \sum_{k=0}^{\infty}(-1)^k\binom{n+k-1}{k}x^k$
$(1+rx)^{-n}$	$\binom{-n}{0} + \binom{-n}{1}rx + \binom{-n}{2}r^2x^2 + \cdots = \sum_{k=0}^{\infty}(-1)^k\binom{n+k-1}{k}r^kx^k$
$(1-x)^{-n}$	$\binom{-n}{0} + \binom{-n}{1}(-x) + \binom{-n}{2}(-x)^2 + \cdots = \sum_{k=0}^{\infty} \binom{n+k-1}{k}x^k$
$(1-rx)^{-n}$	$\binom{-n}{0} + \binom{-n}{1}(-rx) + \binom{-n}{2}(-rx)^2 + \cdots = \sum_{k=0}^{\infty} \binom{n+k-1}{k}r^kx^k$
$\frac{x^n}{(1-x)^{n+1}}$	$\binom{n}{n}x^n + \binom{n+1}{n}x^{n+1} + \binom{n+2}{n}x^{n+2} + \cdots = \sum_{k=n}^{\infty} \binom{k}{n}x^k$

8. For any real number r, the Maclaurin series expansion for $(1+x)^r$ is

$$(1+x)^r = \binom{r}{0}1 + \binom{r}{1}x + \binom{r}{2}x^2 + \cdots,$$

where $\binom{r}{k} = \frac{r(r-1)(r-2)\ldots(r-k+1)}{k!}$ if $k > 0$ and $\binom{r}{0} = 1$.

9. Using Example 8, the expansion of $f(x) = \sqrt{1+x}$ is

$$\begin{aligned}\sqrt{1+x} = (1+x)^{1/2} &= \binom{1/2}{0}1 + \binom{1/2}{1}x + \binom{1/2}{2}x^2 + \cdots \\ &= 1 + \tfrac{1}{2}x + \frac{\frac{1}{2}\cdot\frac{-1}{2}}{2!}x^2 + \frac{\frac{1}{2}\cdot\frac{-1}{2}\cdot\frac{-3}{2}}{3!}x^3 + \frac{\frac{1}{2}\cdot\frac{-1}{2}\cdot\frac{-3}{2}\cdot\frac{-5}{2}}{4!}x^4 + \cdots \\ &= 1 + \tfrac{1}{2}x - \tfrac{1}{8}x^2 + \tfrac{1}{16}x^3 - \tfrac{5}{128}x^4 + \cdots .\end{aligned}$$

Thus $\sqrt{1+x}$ is the generating function for the sequence $1, \frac{1}{2}, -\frac{1}{8}, \frac{1}{16}, -\frac{5}{128}, \ldots$.

10. Vandermonde's convolution identity (§2.3.4) can be obtained from the generating functions $f(x) = (1+x)^m$ and $g(x) = (1+x)^n$. First, $(1+x)^m(1+x)^n = (1+x)^{m+n}$. Equating coefficients of x^r on both sides of this equation and using Table 3 produces

$$\sum_{k=0}^{m} \binom{m}{k}\binom{n}{r-k} = \binom{m+n}{r}.$$

11. Twenty identical computer terminals are to be distributed into five distinct rooms so each room receives at least two terminals. The number of such distributions is the coefficient of x^{20} in the expansion of $f(x) = (x^2+x^3+x^4+\cdots)^5 = x^{10}(1+x+x^2+\cdots)^5 = \frac{x^{10}}{(1-x)^5}$. Thus the coefficient of x^{20} in $f(x)$ is the coefficient of x^{10} in $(1-x)^{-5}$, which from Table 3 is $\binom{5+10-1}{10} = \binom{14}{10} = 1{,}001$.

12. Suppose in Example 11 that each room can accommodate at most seven terminals. Now the generating function is $g(x) = (x^2+x^3+x^4+x^5+x^6+x^7)^5 = x^{10}(1+x+x^2+x^3+x^4+x^5)^5 = x^{10}\left(\frac{1-x^6}{1-x}\right)^5$. Consequently, the number of allowable distributions is the coefficient of x^{10} in $\left(\frac{1-x^6}{1-x}\right)^5 = (1-x^6)^5(1-x)^{-5} = \left[1-\binom{5}{1}x^6+\binom{5}{2}x^{12}-\cdots-x^{30}\right]\left[\binom{-5}{0}+\binom{-5}{1}(-x)+\binom{-5}{2}(-x)^2+\cdots\right]$. This coefficient is $\left[\binom{-5}{10}(-1)^{10}-\binom{5}{1}\binom{-5}{4}(-1)^4\right] = \binom{14}{10} - \binom{5}{1}\binom{8}{4} = 651$.

13. *Unordered selections with replacement*: k objects are selected from n distinct objects, with repetition allowed. For each of the n distinct objects, the power series $1+x+x^2+\cdots$ represents the possible choices (namely none, one, two, ...) for that object. The generating function for all n objects is then

$$f(x) = (1+x+x^2+\cdots)^n = \left(\tfrac{1}{1-x}\right)^n = (1-x)^{-n} = \textstyle\sum_{k=0}^{\infty}\binom{n+k-1}{k}x^k.$$

The number of selections with replacement is the coefficient of x^k in $f(x)$, namely $\binom{n+k-1}{k}$.

14. Suppose there are p types of objects, with n_i indistinguishable objects of type i. The number of ways to pick a total of k objects (where the number of selected objects of type i is at most n_i) is the coefficient of x^k in the generating function

$$\prod_{i=1}^{p}(1+x+x^2+\cdots+x^{n_i}).$$

15. *Partitions*: Generating functions can be found for $p(n)$, the number of partitions of the positive integer n (§2.5.1). The number of 1s that appear as summands in a partition of n is 0 or 1 or 2 or ..., recorded as the terms in the power series $1+x+x^2+x^3+\cdots$. The power series $1+x^2+x^4+x^6+\cdots$ records the number of 2s that can appear in a partition of n, and so forth. For example, $p(12)$ is the coefficient of x^{12} in

$$(1+x+x^2+\cdots)(1+x^2+x^4+\cdots)\ldots(1+x^{12}+x^{24}+\cdots) = \prod_{i=1}^{12}\tfrac{1}{1-x^i},$$

or in $(1+x+x^2+\cdots+x^{12})(1+x^2+x^4+\cdots+x^{12})\dots(1+x^{12})$. In general, the function $P(x) = \prod_{i=1}^{\infty}\frac{1}{1-x^i}$ is the generating function for the sequence $p(0), p(1), p(2), \dots$, where $p(0)$ is defined as 1.

16. The function $P_d(x) = (1+x)(1+x^2)(1+x^3)\dots = \prod_{i=1}^{\infty}(1+x^i)$ generates $Q(n)$, the number of partitions of n into distinct summands (see §2.5.1). The function $P_o(x) = \frac{1}{1-x}\cdot\frac{1}{1-x^3}\cdot\frac{1}{1-x^5}\dots = \prod_{j=0}^{\infty}(1-x^{2j+1})^{-1}$ is the generating function for $\mathcal{O}(n)$, the number of partitions of n with all summands odd (see §2.5.1). Then

$$\begin{aligned} P_d(x) &= (1+x)(1+x^2)(1+x^3)(1+x^4)\dots \\ &= \tfrac{1-x^2}{1-x}\cdot\tfrac{1-x^4}{1-x^2}\cdot\tfrac{1-x^6}{1-x^3}\cdot\tfrac{1-x^8}{1-x^4}\dots = \tfrac{1}{1-x}\cdot\tfrac{1}{1-x^3}\dots = P_o(x), \end{aligned}$$

so $Q(n) = \mathcal{O}(n)$ for every nonnegative integer n.

17. *Summation formulas*: Generating functions can be used to produce the formula $1^2+2^2+\cdots+n^2 = \frac{1}{6}n(n+1)(2n+1)$. (See §3.5.4 for an extensive tabulation of summation formulas.) Manipulating the expansion $(1-x)^{-1} = 1+x+x^2+x^3+\cdots$ produces

$$x\tfrac{d}{dx}\left[x\tfrac{d}{dx}(1-x)^{-1}\right] = \tfrac{x(1+x)}{(1-x)^3} = x + 2^2x^2 + 3^2x^3 + \cdots.$$

So $\frac{x(1+x)}{(1-x)^3}$ is the generating function for the sequence $0^2, 1^2, 2^2, 3^2, \dots$ and, by Fact 7, $\frac{x(1+x)}{(1-x)^4}$ generates the sequence $0^2, 0^2+1^2, 0^2+1^2+2^2, 0^2+1^2+2^2+3^2, \dots$. Consequently, $\sum_{i=0}^{n} i^2$ is the coefficient of x^n in

$$(x+x^2)(1-x)^{-4} = (x+x^2)\left[\tbinom{-4}{0} + \tbinom{-4}{1}(-x) + \tbinom{-4}{2}(-x)^2 + \cdots\right].$$

The answer is then $\binom{-4}{n-1}(-1)^{n-1} + \binom{-4}{n-2}(-1)^{n-2} = \binom{n+2}{n-1} + \binom{n+1}{n-2} = \frac{1}{6}n(n+1)(2n+1)$.

18. *Catalan numbers*: The Catalan numbers (§3.1.3) $C_0, C_1, C_2, \dots$ satisfy the recurrence relation $C_n = C_0C_{n-1} + C_1C_{n-2} + \cdots + C_{n-1}C_0$, $n \geq 1$, with $C_0 = 1$. (See §3.3.1.) Hence their generating function $f(x) = \sum_{k=0}^{\infty} C_k x^k$ satisfies $xf^2(x) = f(x) - 1$, yielding $f(x) = \frac{1}{2x}(1-\sqrt{1-4x}) = \frac{1}{2x}(1-(1-4x)^{1/2})$. (The negative square root is chosen since the numbers C_i cannot be negative.) Applying Example 8 to $(1-4x)^{1/2}$ yields $f(x) = \frac{1}{2x}\left[1 - \sum_{k=0}^{\infty}\binom{1/2}{k}(-4)^k x^k\right] = \frac{1}{2x}\left[1 - \sum_{k=0}^{\infty}\frac{-1}{2k-1}\binom{2k}{k}x^k\right] = \sum_{k=0}^{\infty}\frac{1}{k+1}\binom{2k}{k}x^k$. Thus $C_n = \frac{1}{n+1}\binom{2n}{n}$.

3.2.2 EXPONENTIAL GENERATING FUNCTIONS

Encoding the terms of a sequence as coefficients of $\frac{x^k}{k!}$ is often helpful in obtaining information about a sequence, such as in counting permutations of objects (where the order of listing objects is important). The functions that result are called exponential generating functions.

Definitions:

The ***exponential generating function*** for the sequence $a_0, a_1, a_2, \dots$ of real numbers is the formal power series $f(x) = a_0 + a_1x + a_2\frac{x^2}{2!} + \cdots = \sum_{i=0}^{\infty} a_i\frac{x^i}{i!}$ or any equivalent closed form expression.

The ***binomial convolution*** of the sequence $a_0, a_1, a_2, \dots$ and the sequence $b_0, b_1, b_2, \dots$ is the sequence $c_0, c_1, c_2, \dots$ in which $c_t = \binom{t}{0}a_0b_t + \binom{t}{1}a_1b_{t-1} + \binom{t}{2}a_2b_{t-2} + \cdots + \binom{t}{t}a_tb_0 = \sum_{k=0}^{t}\binom{t}{k}a_kb_{t-k}$, the coefficient of $\frac{x^t}{t!}$.

Facts:

1. Each sequence $\{a_n\}$ defines a *unique* exponential generating function $f(x)$, and conversely.

2. *Related exponential generating functions*: Suppose $f(x) = \sum_{k=0}^{\infty} a_k \frac{x^k}{k!}$ and $g(x) = \sum_{k=0}^{\infty} b_k \frac{x^k}{k!}$ are exponential generating functions for the sequences $a_0, a_1, a_2, \ldots$ and $b_0, b_1, b_2, \ldots$, respectively. Table 4 gives some related exponential generating functions. [Here $P(n,k) = \binom{n}{k}k! = \frac{n!}{(n-k)!}$ is the number of k-permutations of a set with n distinct objects. (See §2.3.1.)]

Table 4: Related exponential generating functions.

generating function	*closed form*
$xf(x)$	$0, a_0, 2a_1, 3a_2, \ldots, (k+1)a_k, \ldots$
$x^n f(x)$	$\underbrace{0,0,0,\ldots,0}_{n}, P(n,n)a_0, P(n+1,n)a_1, \ldots, P(n+k,n)a_k, \ldots$
$f'(x)$	$a_1, a_2, a_3, \ldots, a_k, \ldots$
$\int_0^x f(t)dt$	$0, a_0, a_1, a_2, \ldots$
$rf(x) + sg(x)$	$ra_0 + sb_0, ra_1 + sb_1, ra_2 + sb_2, \ldots$
$f(x)g(x)$	$\binom{0}{0}a_0b_0,\ \binom{1}{0}a_0b_1 + \binom{1}{1}a_1b_0,\ \binom{2}{0}a_0b_2 + \binom{2}{1}a_1b_1 + \binom{2}{2}a_2b_0,\ \ldots$ (binomial convolution of $\{a_k\}$ and $\{b_k\}$)

Examples:

1. The binomial theorem (§2.3.4) gives

$$\begin{aligned}(1+x)^n &= \tbinom{n}{0} + \tbinom{n}{1}x + \tbinom{n}{2}x^2 + \tbinom{n}{3}x^3 + \cdots + \tbinom{n}{n}x^n \\ &= P(n,0) + P(n,1)x + P(n,2)\tfrac{x^2}{2!} + P(n,3)\tfrac{x^3}{3!} + \cdots + P(n,n)\tfrac{x^n}{n!}.\end{aligned}$$

Hence $(1+x)^n$ is the exponential generating function for the sequence $P(n,0)$, $P(n,1)$, $P(n,2)$, $P(n,3)$, $\ldots, P(n,n), 0, 0, 0, \ldots$.

2. The Maclaurin series expansion for e^x is $e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$, so the function e^x is the exponential generating function for the sequence $1, 1, 1, 1, \ldots$. The function $e^{-x} = 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \cdots$ is the exponential generating function for the sequence $1, -1, 1, -1, \ldots$. Consequently,

$$\tfrac{1}{2}(e^x + e^{-x}) = 1 + \tfrac{x^2}{2!} + \tfrac{x^4}{4!} + \cdots$$

is the exponential generating function for $1, 0, 1, 0, 1, 0, \ldots$, while

$$\tfrac{1}{2}(e^x - e^{-x}) = x + \tfrac{x^3}{3!} + \tfrac{x^5}{5!} + \cdots$$

is the exponential generating function for $0, 1, 0, 1, 0, 1, \ldots$.

3. The function $f(x) = \frac{1}{1-x} = \sum_{i=0}^{\infty} x^i = \sum_{i=0}^{\infty} i! \frac{x^i}{i!}$ is the exponential generating function for the sequence $0!, 1!, 2!, 3!, \ldots$.

4. Table 5 gives closed form expressions for the exponential generating functions of particular sequences. In this table, $\left[{n \atop k}\right]$ is a Stirling cycle number, $\left\{{n \atop k}\right\}$ is a Stirling subset number, B_n is the nth Bell number (§2.5.2), and D_n is the number of derangements of n objects (§2.4.2).

Table 5: Exponential generating functions for particular sequences.

sequence	*closed form*
$1, 1, 1, 1, 1, \ldots$	e^x
$1, -1, 1, -1, 1, \ldots$	e^{-x}
$1, 0, 1, 0, 1, \ldots$	$\frac{1}{2}(e^x + e^{-x})$
$0, 1, 0, 1, 0, \ldots$	$\frac{1}{2}(e^x - e^{-x})$
$0, 1, 2, 3, 4, \ldots$	xe^x
$P(n,0), P(n,1), \ldots, P(n,n), 0, 0, \ldots$	$(1+x)^n$
$0, \ldots, 0, \left[{n \atop n}\right], \left[{n+1 \atop n}\right], \ldots$	$\frac{1}{n!}\left[\ln\frac{1}{(1-x)}\right]^n$
$0, \ldots, 0, \left\{{n \atop n}\right\}, \left\{{n+1 \atop n}\right\}, \ldots$	$\frac{1}{n!}\left[e^x - 1\right]^n$
$B_0, B_1, B_2, B_3, B_4, \ldots$	e^{e^x-1}
$D_0, D_1, D_2, D_3, D_4, \ldots$	$\frac{e^{-x}}{1-x}$

5. The number of ways to permute five of the eight letters in TERMINAL is found using the exponential generating function $f(x) = (1+x)^8$. Here each of the eight letters in TERMINAL is accounted for by the factor $(1+x)$, where $1\,(=x^0)$ indicates the letter does not occur in the permutation and $x\,(=x^1)$ indicates that it does. The coefficient of $\frac{x^5}{5!}$ in $f(x)$ is $\binom{8}{5}5! = P(8,5) = 6{,}720$.

6. The number of ways to permute five of the letters in TRANSPORTATION is found as the coefficient of $\frac{x^5}{5!}$ in the exponential generating function $f(x) = (1+x+\frac{x^2}{2!}+\frac{x^3}{3!})(1+x+\frac{x^2}{2!})^4(1+x)^3$. Here the factor $1+x+\frac{x^2}{2!}+\frac{x^3}{3!}$ accounts for the letter T which can be used 0, 1, 2, or 3 times. The factor $1+x+\frac{x^2}{2!}$ occurs four times—for each of R, A, N, and O. Each of the letters S, P, and I produces the factor $(1+x)$. The coefficient of x^5 in $f(x)$ is found to be $\frac{487}{3}$, so the answer is $(\frac{487}{3})5! = 19{,}480$.

7. The number of ternary sequences (made up of 0s, 1s, and 2s) of length 10 with at least one 0 and an odd number of 1s can be found using the exponential generating function

$$\begin{aligned} f(x) &= (x + \tfrac{x^2}{2!} + \tfrac{x^3}{3!} + \cdots)(x + \tfrac{x^3}{3!} + \tfrac{x^5}{5!} + \cdots)(1 + x + \tfrac{x^2}{2!} + \tfrac{x^3}{3!} + \cdots) \\ &= (e^x - 1)\tfrac{1}{2}(e^x - e^{-x})e^x = \tfrac{1}{2}(e^{3x} - e^{2x} - e^x + 1) \\ &= \tfrac{1}{2}\left(\sum_{i=0}^{\infty}\frac{(3x)^i}{i!} - \sum_{i=0}^{\infty}\frac{(2x)^i}{i!} - \sum_{i=0}^{\infty}\frac{x^i}{i!} + 1\right). \end{aligned}$$

The answer is the coefficient of $\frac{x^{10}}{10!}$ in $f(x)$, which is $\frac{1}{2}(3^{10} - 2^{10} - 1^{10}) = 29{,}012$.

8. Suppose in Example 7 that no symbol may occur exactly two times. The exponential generating function is then $f(x) = (1+x+\frac{x^3}{3!}+\frac{x^4}{4!}+\cdots)^3 = (e^x - \frac{x^2}{2})^3 = e^{3x} - \frac{3}{2}x^2e^{2x} + \frac{3}{4}x^4e^x - \frac{1}{8}x^6$. The number of ternary sequences is the coefficient of $\frac{x^{10}}{10!}$ in $f(x)$, namely $3^{10} - \frac{3}{2}(10)(9)2^8 + \frac{3}{4}(10)(9)(8)(7)1^6 = 28{,}269$.

9. Exponential generating functions can be used to count the number of onto functions $\varphi\colon A \to B$ where $|A| = m$ and $|B| = n$. Each such function is specified by the sequence of m values $\varphi(a_1), \varphi(a_2), \ldots, \varphi(a_m)$, where each element $b \in B$ occurs at least once in this sequence. Element b contributes a factor $(x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots) = (e^x - 1)$ to the exponential generating function $f(x) = (e^x - 1)^n$. The number of onto functions is the coefficient of $\frac{x^m}{m!}$ in $f(x)$, or $n!$ times the coefficient of $\frac{x^m}{m!}$ in $\frac{(e^x-1)^n}{n!}$. From Table 5, the answer is then $n!\left\{{m \atop n}\right\}$. (Also see §2.5.2.)

3.3 RECURRENCE RELATIONS

In a number of counting problems, it may be difficult to find the solution directly. However, it is frequently possible to express the solution to a problem of a given size in terms of solutions to problems of smaller size. This interdependence of solutions produces a recurrence relation. Although there is no practical systematic way to solve all recurrence relations, this section contains methods for solving certain types of recurrence relations, thereby providing an explicit formula for the original counting problem. The topic of recurrence relations provides the discrete counterpart to concepts in the study of ordinary differential equations.

3.3.1 BASIC CONCEPTS

Definitions:

A ***recurrence relation*** for the sequence $a_0, a_1, a_2, \ldots$ is an equation relating the term a_n to certain of the preceding terms a_i, $i < n$, for each $n \geq n_0$.

The recurrence relation is ***linear*** if it expresses a_n as a linear function of a fixed number of preceding terms. Otherwise the relation is ***nonlinear***.

The recurrence relation is ***kth-order*** if a_n can be expressed in terms of $a_{n-1}, a_{n-2}, \ldots,$ a_{n-k}.

The recurrence relation is ***homogeneous*** if the zero sequence $a_0 = a_1 = \cdots = 0$ satisfies the relation. Otherwise the relation is ***nonhomogeneous***.

A kth-order linear homogeneous recurrence relation ***with constant coefficients*** is an equation of the form $C_0 a_n + C_1 a_{n-1} + \cdots + C_k a_{n-k} = 0$, $n \geq k$, where the C_i are real constants with $C_0 \neq 0$, $C_k \neq 0$. ***Initial conditions*** for this recurrence relation specify particular values for k of the a_i (typically $a_0, a_1, \ldots, a_{k-1}$).

Facts:

1. A kth-order linear homogeneous recurrence relation with constant coefficients can also be written $C_0 a_{n+k} + C_1 a_{n+k-1} + \cdots + C_k a_n = 0$, $n \geq 0$.

2. There are in general an infinite number of solution sequences $\{a_n\}$ to a kth-order linear homogeneous recurrence relation (with constant coefficients).

3. A kth-order linear homogeneous recurrence relation with constant coefficients together with k initial conditions on consecutive terms $a_0, a_1, \ldots, a_{k-1}$ uniquely determines the sequence $\{a_n\}$. This is not necessarily the case for nonlinear relations (see Example 2) or when nonconsecutive initial conditions are specified (see Example 3).

4. The same recurrence relation can be written in different forms by adjusting the subscripts. For example, the recurrence relation $a_n = 3a_{n-1}$, $n \geq 1$, can be written as $a_{n+1} = 3a_n$, $n \geq 0$.

Examples:

1. The relation $a_n - a_{n-1}^2 + 2a_{n-2} = 0$, $n \geq 2$, is a nonlinear homogeneous recurrence relation with constant coefficients. If the initial conditions $a_0 = 0$, $a_1 = 1$ are imposed, this defines a unique sequence $\{a_n\}$ whose first few terms are $0, 1, 1, -1, -1, 3, 11, 115, \ldots$.

2. The first-order (constant coefficient) recurrence relation $a_{n+1}^2 - a_n = 3$, $a_0 = 1$ is nonhomogeneous and nonlinear. Even though one initial condition is specified, this does not uniquely specify a solution sequence. Namely, the two sequences $1, -2, 1, 2, \ldots$ and $1, -2, -1, \sqrt{2}, \ldots$ satisfy the recurrence relation and the given initial condition.

3. The second-order relation $a_{n+2} - a_n = 0$, $n \geq 0$, with nonconsecutive initial conditions $a_1 = a_3 = 0$ does not uniquely specify a solution sequence. Both $a_n = (-1)^n + 1$ and $a_n = 2(-1)^n + 2$ satisfy the recurrence and the given initial conditions.

4. *Compound interest*: If an initial investment of P dollars is made at a rate of r percent compounded annually, then the amount a_n after n years is given by the recurrence relation $a_n = a_{n-1}(1 + \frac{r}{100})$, where $a_0 = P$. [The amount at the end of the nth year is equal to the amount a_{n-1} at the end of the $(n-1)$st year plus the interest on a_{n-1}, namely $\frac{r}{100}a_{n-1}$.]

5. *Fibonacci sequence*: The Fibonacci numbers satisfy the second-order linear homogeneous recurrence relation $a_n - a_{n-1} - a_{n-2} = 0$.

6. *Bit strings*: Let a_n be the number of bit strings of length n. Then $a_0 = 1$ (the empty string) and $a_n = 2a_{n-1}$ if $n > 0$. [Every bit string of length $n - 1$ gives rise to two bit strings of length n, by placing a 0 or a 1 at the end of the string of length $n - 1$.]

7. *Bit strings with no consecutive* 0*s*: See Example 12 of §3.3.2.

8. *Permutations*: Let a_n denote the number of permutations of $\{1, 2, \ldots, n\}$. Then a_n satisfies the first-order linear homogeneous recurrence relation (with nonconstant coefficients) $a_{n+1} = (n + 1)a_n$, $n \geq 1$, $a_1 = 1$. This follows since any n-permutation π can be transformed into an $(n+1)$-permutation by inserting the element $n+1$ into any of the $n+1$ available positions—either at the beginning or end of π, or between two adjacent elements of π. To solve for a_n, repeatedly apply the recurrence relation and its initial condition: $a_n = na_{n-1} = n(n - 1)a_{n-2} = n(n - 1)(n - 2)a_{n-3} = \cdots = n(n - 1)(n - 2) \ldots 2a_1 = n!$.

9. *Catalan numbers*: The Catalan numbers (§3.1.3, §3.3.1) satisfy the nonlinear homogeneous recurrence relation $C_n - C_0C_{n-1} - C_1C_{n-2} - \cdots - C_{n-1}C_0 = 0$, $n \geq 1$, with initial condition $C_0 = 1$. Given the product of $n + 1$ variables $x_1x_2 \ldots x_{n+1}$, let C_n be the number of ways in which the multiplications can be carried out. For example, there are five ways to form the product $x_1x_2x_3x_4$: $((x_1x_2)x_3)x_4$, $(x_1(x_2x_3))x_4$, $(x_1x_2)(x_3x_4)$, $x_1((x_2x_3)x_4)$, and $x_1(x_2(x_3x_4))$. No matter how the multiplications are performed, there will be an outermost product of the form $(x_1x_2 \ldots x_i)(x_{i+1} \ldots x_{n+1})$. The number of ways in which the product $x_1x_2 \ldots x_i$ can be formed is C_{i-1} and the number of ways in which the product $x_{i+1} \ldots x_{n+1}$ can be formed is C_{n-i}. Thus, $(x_1x_2 \ldots x_i)(x_{i+1} \ldots x_{n+1})$ can be obtained in $C_{i-1}C_{n-i}$ ways. Summing these over the values $i = 1, 2, \ldots, n$ yields the recurrence relation.

10. *Tower of Hanoi*: See Example 1 of §2.2.4.

11. *Onto functions*: The number of onto functions $\varphi\colon A \to B$ can be found by developing a nonhomogeneous linear recurrence relation based on the size of B. Let $|A| = m$ and let a_n be the number of onto functions from A to a set with n elements. Then $a_n = n^m - \binom{n}{1}a_1 - \binom{n}{2}a_2 - \cdots - \binom{n}{n-1}a_{n-1}$, $n \geq 2$, $a_1 = 1$. This follows since the total number of functions from A to B is n^m and the number of functions that map A onto a proper subset of B with exactly j elements is $\binom{n}{j}a_j$.

For example, if $m = 7$ and $n = 4$, applying this recursion gives $a_2 = 2^7 - 2(1) = 126$, $a_3 = 3^7 - 3(1) - 3(126) = 1{,}806$, $a_4 = 4^7 - 4(1) - 6(126) - 4(1{,}806) = 8{,}400$. Thus there are 8,400 onto functions in this case.

3.3.2 HOMOGENEOUS RECURRENCE RELATIONS

It is assumed throughout this subsection that the recurrence relations are linear with constant coefficients.

Definitions:

A ***geometric progression*** is a sequence $a_0, a_1, a_2, \ldots$ for which $\frac{a_1}{a_0} = \frac{a_2}{a_1} = \cdots = \frac{a_{n+1}}{a_n} = \cdots = r$, the ***common ratio***.

The ***characteristic equation*** for the kth-order recurrence relation $C_0a_n + C_1a_{n-1} + \cdots + C_ka_{n-k} = 0$, $n \geq k$, is the equation $C_0r^k + C_1r^{k-1} + \cdots + C_k = 0$. The ***characteristic roots*** are the roots of this equation.

The sequences $\{a_n^{(1)}\}, \{a_n^{(2)}\}, \ldots, \{a_n^{(k)}\}$ are ***linearly dependent*** if there exist constants $t_1, t_2, \ldots, t_k$, not all zero, such that $\sum_{i=1}^{k} t_ia_n^{(i)} = 0$ for all $n \geq 0$. Otherwise, they are ***linearly independent***.

Facts:

1. *General method for solving a linear homogeneous recurrence relation with constant coefficients*: First find the general solution. Then use the initial conditions to find the particular solution.

2. If the k characteristic roots $r_1, r_2, \ldots, r_k$ are distinct, then $r_1^n, r_2^n, \ldots, r_k^n$ are linearly independent solutions of the homogeneous recurrence relation. The general solution is $a_n = c_1r_1^n + c_2r_2^n + \cdots + c_kr_k^n$, where $c_1, c_2, \ldots, c_k$ are arbitrary constants.

3. If a characteristic root r has multiplicity m, then $r^n, nr^n, \ldots, n^{m-1}r^n$ are linearly independent solutions of the homogeneous recurrence relation. The linear combination $c_1r^n + c_2nr^n + \cdots + c_mn^{m-1}r^n$ is also a solution, where $c_1, c_2, \ldots, c_m$ are arbitrary constants.

4. Facts 2 and 3 can be used together. If there are k characteristic roots $r_1, r_2, \ldots, r_k$, with respective multiplicities $m_1, m_2, \ldots, m_k$ (where some of the m_i can equal 1), the the general solution is a sum of sums, each of the form appearing in Fact 3.

5. *de Moivre's theorem*: For any positive integer n, $(\cos\theta + i\sin\theta)^n = \cos n\theta + i\sin n\theta$. This result is used to find solutions of recurrence relations when the characteristic roots are complex numbers. (See Example 10.)

6. *Solving first-order recurrence relations*: The solution of the homogeneous recurrence relation $a_{n+1} = da_n$, $n \geq 0$, with initial condition $a_0 = A$, is $a_n = Ad^n$, $n \geq 0$.

7. *Solving second-order recurrence relations*: Let r_1, r_2 be the characteristic roots associated with the second-order homogeneous relation $C_0a_n + C_1a_{n-1} + C_2a_{n-2} = 0$. There are three possibilities:

- r_1, r_2 are distinct real numbers: r_1^n and r_2^n are linearly independent solutions of the recurrence relation. The general solution has the form

$$a_n = c_1r_1^n + c_2r_2^n,$$

where the constants c_1, c_2 are found from the values of a_n for two distinct values of n (often $n = 0, 1$).

- r_1, r_2 form a complex conjugate pair $a \pm bi$: The general solution is

$$a_n = c_1(a+bi)^n + c_2(a-bi)^n = (\sqrt{a^2+b^2})^n(k_1\cos n\theta + k_2\sin n\theta),$$

with $\theta = \arctan(b/a)$. Here $(\sqrt{a^2+b^2})^n \cos n\theta$ and $(\sqrt{a^2+b^2})^n \sin n\theta$ are linearly independent solutions.

- r_1, r_2 are real and equal: r_1^n and nr_1^n are linearly independent solutions of the recurrence relation. The general solution is

$$a_n = c_1 r_1^n + c_2 n r_1^n.$$

Examples:

1. The geometric progression $7, 21, 63, 189, \ldots$, with common ratio 3, satisfies the first-order homogeneous recurrence relation $a_{n+1} - 3a_n = 0$ for all $n \geq 0$.

2. The first-order homogeneous recurrence relation $a_{n+1} = 3a_n$, $n \geq 0$, does not determine a *unique* geometric progression. Any geometric sequence with ratio 3 is a solution; for example the geometric progression in Example 1 (with $a_0 = 7$), as well as the geometric progression $5, 15, 45, 135, \ldots$ (with $a_0 = 5$).

3. The first-order recurrence relation $a_{n+1} = 3a_n$, $n \geq 0$, $a_0 = 7$ is easily solved using Fact 6. The general solution is $a_n = 7(3^n)$ for all $n \geq 0$.

4. *Compound interest*: If interest is compounded quarterly, how long does it take for an investment of \$500 to double when the annual interest rate is 8%? If a_n denotes the value of the investment after n quarters have passed, then $a_{n+1} = a_n + 0.02a_n = (1.02)a_n$, $n \geq 0$, $a_0 = 500$. [Here the quarterly rate is $0.08/4 = 0.02 = 2\%$.] By Fact 6, the solution is $a_n = 500(1.02)^n$, $n \geq 0$. The investment doubles when $1000 = 500(1.02)^n$, so $n = \frac{\log 2}{\log 1.02} \approx 35.003$. Consequently, after 36 quarters (or 9 years) the initial investment of \$500 (more than) doubles.

5. *Population growth*: The number of bacteria in a culture (approximately) triples in size every hour. If there are (approximately) 100,000 bacteria in a culture after six hours, how many were there at the start? Define p_n to be the number of bacteria in the culture after n hours have elapsed. Then $p_{n+1} = 3p_n$ for $n \geq 0$. From Fact 6, $p_n = p_0(3^n)$. So $100{,}000 = p_0(3^6)$ and $p_0 \approx 137$.

6. *Fibonacci sequence*: The Fibonacci sequence $0, 1, 1, 2, 3, 5, 8, 13, \ldots$ arises in varied applications (§3.1.2). Its terms satisfy the second-order homogeneous recurrence relation $F_n = F_{n-1} + F_{n-2}$, $n \geq 2$, with initial conditions $F_0 = 0$, $F_1 = 1$. An explicit formula can be obtained for F_n using Fact 7. The characteristic equation is $r^2 - r - 1 = 0$, with distinct real roots $\frac{1 \pm \sqrt{5}}{2}$. Thus the general solution is

$$F_n = c_1\left(\tfrac{1+\sqrt{5}}{2}\right)^n + c_2\left(\tfrac{1-\sqrt{5}}{2}\right)^n.$$

Using the initial conditions $F_0 = 0$, $F_1 = 1$ gives $c_1 = \frac{1}{\sqrt{5}}$, $c_2 = -\frac{1}{\sqrt{5}}$ and the explicit formula

$$F_n = \tfrac{1}{\sqrt{5}}\left[\left(\tfrac{1+\sqrt{5}}{2}\right)^n - \left(\tfrac{1-\sqrt{5}}{2}\right)^n\right], \quad n \geq 0.$$

7. *Lucas sequence*: Related to the sequence of Fibonacci numbers is the sequence of Lucas numbers $2, 1, 3, 4, 7, 11, 18, \ldots$ (see §3.1.2). The terms of this sequence satisfy the same second-order homogeneous recurrence relation $L_n = L_{n-1} + L_{n-2}$, $n \geq 2$, but with the different initial conditions $L_0 = 2$, $L_1 = 1$. The formula for L_n is

$$L_n = \left(\tfrac{1+\sqrt{5}}{2}\right)^n + \left(\tfrac{1-\sqrt{5}}{2}\right)^n, \quad n \geq 0.$$

8. *Random walk*: A particle undergoes a random walk in one dimension, along the x-axis. Barriers are placed at positions $x = 0$ and $x = T$. At any instant, the particle moves with probability p one unit to the right; with probability $q = 1-p$ it moves one unit to the left. Let a_n denote the probability that the particle, starting at position $x = n$, reaches the barrier $x = T$ before it reaches the barrier $x = 0$. It can be reasoned that a_n satisfies the second-order recurrence relation $a_n = pa_{n+1} + qa_{n-1}$ or $pa_{n+1} - a_n + qa_{n-1} = 0$. In this case the two initial conditions are $a_0 = 0$ and $a_T = 1$. The characteristic equation $pr^2 - r + q = (pr - q)(r - 1) = 0$ has roots 1, $\frac{q}{p}$. When $p \neq q$, the roots are distinct and the first case of Fact 7 can be used to determine a_n; when $p = q$, the third case of Fact 7 must be used. (Explicit solutions are given in §7.5.2, Fact 10.)

9. The second-order relation $a_n + 4a_{n-1} - 21a_{n-2} = 0$, $n \geq 2$, has the characteristic equation $r^2 + 4r - 21 = 0$, with distinct real roots 3 and -7. The general solution to the recurrence relation is

$$a_n = c_1(3^n) + c_2(-7)^n, \quad n \geq 0,$$

where c_1, c_2 are arbitrary constants. If the initial conditions specify $a_0 = 1$ and $a_1 = 1$, then solving the equations $1 = a_0 = c_1 + c_2$, $1 = a_1 = 3c_1 - 7c_2$ gives $c_1 = \frac{4}{5}$, $c_2 = \frac{1}{5}$. In this case, the unique solution is

$$a_n = \tfrac{4}{5}(3^n) + \tfrac{1}{5}(-7)^n, \quad n \geq 0.$$

10. The second-order relation $a_n - 6a_{n-1} + 58a_{n-2} = 0$, $n \geq 2$, has the characteristic equation $r^2 - 6r + 58 = 0$, with complex conjugate roots $r = 3 \pm 7i$. The general solution is

$$a_n = c_1(3 + 7i)^n + c_2(3 - 7i)^n, \quad n \geq 0.$$

Using Fact 5, $(3 + 7i)^n = [\sqrt{3^2 + 7^2}(\cos\theta + i\sin\theta)]^n = (\sqrt{58}\,)^n(\cos n\theta + i\sin n\theta)$, where $\theta = \arctan\frac{7}{3}$. Likewise $(3 - 7i)^n = (\sqrt{58}\,)^n(\cos n\theta - i\sin n\theta)$. This gives the general solution

$$a_n = (\sqrt{58}\,)^n[(c_1 + c_2)\cos n\theta + (c_1 - c_2)i\sin n\theta] = (\sqrt{58}\,)^n(k_1\cos n\theta + k_2\sin n\theta).$$

If the initial conditions $a_0 = 1$ and $a_1 = 1$ are specified, then $1 = a_0 = k_1$, $1 = a_1 = \sqrt{58}\,(\cos\theta + k_2\sin\theta)$, yielding $k_1 = 1$, $k_2 = -\frac{2}{7}$. Thus

$$a_n = (\sqrt{58}\,)^n(\cos n\theta - \tfrac{2}{7}\sin n\theta), \quad n \geq 0.$$

11. The second-order relation $a_{n+2} - 6a_{n+1} + 9a_n = 0$, $n \geq 0$, has the characteristic equation $r^2 - 6r + 9 = (r - 3)^2 = 0$, with the repeated roots 3, 3. The general solution to this recurrence is

$$a_n = c_1(3^n) + c_2 n3^n, \quad n \geq 0.$$

If the initial conditions are $a_0 = 2$ and $a_1 = 4$, then $2 = a_0 = c_1$, $4 = 2(3) + c_2(1)(3)$, giving $c_1 = 2$, $c_2 = -\frac{2}{3}$. Thus

$$a_n = 2(3^n) - \tfrac{2}{3}n3^n = 2(3^n - n3^{n-1}), \quad n \geq 0.$$

12. For $n \geq 1$, let a_n count the number of binary strings of length n that contain no consecutive 0s. Here $a_1 = 2$ (for the two strings 0 and 1) and $a_2 = 3$ (for the strings 01, 10, 11). For $n \geq 3$, a string counted in a_n ends in either 1 or 0. If the nth bit is 1, then the preceding $n - 1$ bits provide a string counted in a_{n-1}; if the nth bit is 0 then the last two bits are 10, and the preceding $n - 2$ bits give a string counted in a_{n-2}. Thus $a_n = a_{n-1} + a_{n-2}$, $n \geq 3$, with $a_1 = 2$ and $a_2 = 3$. The solution to this relation is simply $a_n = F_{n+2}$, the Fibonacci sequence shifted two places. An explicit formula for a_n is obtained using the result in Example 6.

13. The third-order recurrence relation $a_{n+3} - a_{n+2} - 4a_{n+1} + 4a_n = 0$, $n \geq 0$, has the characteristic equation $r^3 - r^2 - 4r + 4 = (r-2)(r+2)(r-1) = 0$, with characteristic roots 2, -2, and 1. The general solution is given by

$$a_n = c_1 2^n + c_2(-2)^n + c_3 1^n = c_1 2^n + c_2(-2)^n + c_3, \quad n \geq 0.$$

14. The general solution of the third-order recurrence relation $a_{n+3} - 3a_{n+2} - 3a_{n+1} + a_n = 0$, $n \geq 0$, is

$$a_n = c_1 1^n + c_2 n 1^n + c_3 n^2 1^n = c_1 + c_2 n + c_3 n^2, \quad n \geq 0.$$

Here the characteristic roots are 1, 1, 1.

15. The fourth-order relation $a_{n+4} + 2a_{n+2} + a_n = 0$, $n \geq 0$, has the characteristic equation $r^4 + 2r^2 + 1 = (r^2+1)^2 = 0$. Since the characteristic roots are $\pm i$, $\pm i$, the general solution is

$$\begin{aligned} a_n &= c_1 i^n + c_2(-i)^n + c_3 n i^n + c_4 n(-i)^n \\ &= k_1 \cos \tfrac{n\pi}{2} + k_2 \sin \tfrac{n\pi}{2} + k_3 n \cos \tfrac{n\pi}{2} + k_4 n \sin \tfrac{n\pi}{2}, \ n \geq 0. \end{aligned}$$

3.3.3 NONHOMOGENEOUS RECURRENCE RELATIONS

It is assumed throughout this subsection that the recurrence relations are linear with constant coefficients.

Definition:

The kth-order ***nonhomogeneous*** recurrence relation has the form $C_0 a_n + C_1 a_{n-1} + \cdots + C_k a_{n-k} = f(n)$, $n \geq k$, where $C_0 \neq 0$, $C_k \neq 0$, and $f(n) \neq 0$ for at least one value of n.

Facts:

1. *General solution*: The general solution of the nonhomogeneous kth-order recurrence relation has the form

$$a_n = a_n^{(h)} + a_n^{(p)},$$

where $a_n^{(h)}$ is the general solution of the homogeneous relation $C_0 a_n + C_1 a_{n-1} + \cdots + C_k a_{n-k} = 0$, $n \geq k$, and $a_n^{(p)}$ is a particular solution for the given relation $C_0 a_n + C_1 a_{n-1} + \cdots + C_k a_{n-k} = f(n)$, $n \geq k$.

2. Given the nonhomogeneous first-order relation $C_0 a_n + C_1 a_{n-1} = kr^n$, $n \geq 1$, where r and k are nonzero constants:

- If r^n is *not* a solution of the associated homogeneous relation, then $a_n^{(p)} = Ar^n$ for A a constant.
- If r^n is a solution of the associated homogeneous relation, then $a_n^{(p)} = Bnr^n$ for B a constant.

3. Given the nonhomogeneous second-order relation $C_0 a_n + C_1 a_{n-1} + C_2 a_{n-2} = kr^n$, $n \geq 2$, where r and k are nonzero constants:

- If r^n is *not* a solution of the associated homogeneous relation, then $a_n^{(p)} = Ar^n$ for A a constant.
- If $a_n^{(h)} = c_1 r^n + c_2 r_1^n$, for $r \neq r_1$, then $a_n^{(p)} = Bnr^n$ for B a constant.

- If $a_n^{(h)} = c_1r^n + c_2nr^n$, then $a_n^{(p)} = Cn^2r^n$ for C a constant.

4. Consider the kth-order nonhomogeneous recurrence relation $C_0a_n + C_1a_{n-1} + \cdots + C_ka_{n-k} = f(n)$. If $f(n)$ is a constant multiple of one of the forms in the first column of Table 1, then the associated *trial solution* $t(n)$ is the corresponding entry in the second column of the table. [Here $A, B, A_0, A_1, \ldots, A_t, r, \alpha$ are real constants.]

- If no summand of $t(n)$ solves the associated homogeneous relation, then $a_n^{(p)} = t(n)$ is a particular solution.
- If a summand of $t(n)$ solves the associated homogeneous relation, then multiply $t(n)$ by the *smallest* (positive integer) power of n—say n^s—so that no summand of the adjusted trial solution $n^st(n)$ solves the associated homogeneous relation. Then $a_n^{(p)} = n^st(n)$ is a particular solution.
- If $f(n)$ is a sum of constant multiples of the forms in the first column of Table 1, then (adjusted) trial solutions are formed for each summand using the first two parts of Fact 4. Adding the resulting trial solutions then provides a particular solution of the nonhomogeneous relation.

Table 1: Trial particular solutions for $C_0a_n + C_1a_{n-1} + \cdots + C_ka_{n-k} = f(n)$.

$f(n)$	$t(n)$
c, a constant	A
n^t (t a positive integer)	$A_tn^t + A_{t-1}n^{t-1} + \cdots + A_1n + A_0$
r^n	Ar^n
$\sin n\alpha$	$A\sin n\alpha + B\cos n\alpha$
$\cos n\alpha$	$A\sin n\alpha + B\cos n\alpha$
n^tr^n	$r^n(A_tn^t + A_{t-1}n^{t-1} + \cdots + A_1n + A_0)$
$r^n\sin n\alpha$	$r^n(A\sin n\alpha + B\cos n\alpha)$
$r^n\cos n\alpha$	$r^n(A\sin n\alpha + B\cos n\alpha)$

Examples:

1. Consider the nonhomogeneous relation $a_n + 4a_{n-1} - 21a_{n-2} = 5(4^n)$, $n \geq 2$. The solution is $a_n = a_n^{(h)} + a_n^{(p)}$, where $a_n^{(h)}$ is the solution of $a_n + 4a_{n-1} - 21a_{n-2} = 0$, $n \geq 2$. So

$$a_n^{(h)} = c_1(3^n) + c_2(-7)^n, \quad n \geq 0.$$

From the third entry in Table 1 $a_n^{(p)} = A(4^n)$ for some constant A. Substituting this into the given nonhomogeneous relation yields $A(4^n) + 4A(4^{n-1}) - 21A(4^{n-2}) = 5(4^n)$. Dividing through by 4^{n-2} gives $16A + 16A - 21A = 80$, or $A = 80/11$. Consequently,

$$a_n = c_1(3^n) + c_2(-7)^n + \tfrac{80}{11}(4^n), \quad n \geq 0.$$

If the initial conditions are $a_0 = 1$ and $a_1 = 2$, then c_1 and c_2 are found using $1 = c_1 + c_2 + \frac{80}{11}$, $2 = 3c_1 - 7c_2 + \frac{320}{11}$, yielding

$$a_n = -\tfrac{71}{10}(3^n) + \tfrac{91}{110}(-7)^n + \tfrac{80}{11}(4^n), \quad n \geq 0.$$

2. Suppose the given recurrence relation is $a_n + 4a_{n-1} - 21a_{n-2} = 8(3^n)$, $n \geq 2$. Then it is still true that

$$a_n^{(h)} = c_1(3^n) + c_2(-7)^n, \quad n \geq 0,$$

where c_1 and c_2 are arbitrary constants. By the second part of Fact 3, a particular solution is $a_n^{(p)} = An3^n$. Substituting $a_n^{(p)}$ gives $An3^n + 4A(n-1)3^{n-1} - 21A(n-2)3^{n-2} = 8(3^n)$. Dividing by 3^{n-2} produces $9An + 12A(n-1) - 21A(n-2) = 72$, so $A = \frac{12}{5}$. Thus

$$a_n = c_1(3^n) + c_2(-7)^n + \tfrac{12}{5}n3^n, \quad n \geq 0.$$

3. *Tower of Hanoi*: (See Example 1 of §2.2.4.) If a_n is the minimum number of moves needed to transfer the n disks, then a_n satisfies the first-order nonhomogeneous relation

$$a_n - 2a_{n-1} = 1, \quad n \geq 1,$$

where $a_0 = 0$. Here $a_n^{(h)} = c(2^n)$ for an arbitrary constant c, and $a_n^{(p)} = A$, using the first entry of Table 1. So $A = 2A + 1$ or $A = -1$. Hence $a_n = c(2^n) - 1$ and $0 = a_0 = c(2^0) - 1$ implies $c = 1$, giving

$$a_n = 2^n - 1, \quad n \geq 0.$$

4. How many regions are formed if n lines are drawn in the plane, in general position (no two parallel and no three intersecting at a point)? If a_n denotes the number of regions thus formed, then $a_1 = 2$, $a_2 = 4$, and $a_3 = 7$ are easily determined. A general formula can be found by developing a recurrence relation for a_n. Namely, if line $n+1$ is added to the diagram with a_n regions formed by n lines, this new line intersects all the other n lines. These intersection points partition line $n+1$ into $n+1$ segments, each of which splits an existing region in two. As a result, $a_{n+1} = a_n + (n+1)$, $n \geq 1$, a first-order nonhomogeneous recurrence relation. Solving this relation with the initial condition $a_1 = 1$ produces $a_n = \frac{1}{2}(n^2 + n + 2)$.

3.3.4 METHOD OF GENERATING FUNCTIONS

Generating functions (see §3.2.1) can be used to solve individual recurrence relations as well as simultaneous systems of recurrence relations. This technique is analogous to the use of Laplace transforms in solving systems of differential equations.

Facts:

1. To solve the kth-order recurrence relation $C_0 a_{n+k} + \cdots + C_k a_n = f(n)$, $n \geq 0$, carry out the following steps:

- Multiply both sides of the recurrence equation by x^{n+k} and sum the result.
- Take this new equation, rewrite it in terms of the generating function $f(x) = \sum_{n=0}^{\infty} a_n x^n$ and solve for $f(x)$.
- Expand the expression found for $f(x)$ in terms of powers of x so that the coefficient a_n can be identified.

2. To solve a system of kth-order recurrence relations, carry out the following steps:

- Multiply both sides of each recurrence equation by x^{n+k} and sum the results.
- Rewrite the system of equations in terms of the generating functions $f(x), g(x), \ldots$ for $a_n, b_n, \ldots$, and solve for these generating functions.
- Expand the expressions found for each generating function in terms of powers of x so that the coefficients $a_n, b_n, \ldots$ can be identified.

Examples:

1. The nonhomogeneous first-order relation $a_{n+1} - 2a_n = 1$, $n \ge 0$, $a_0 = 0$, arises in the *Tower of Hanoi* problem (§3.3.3, Example 3). Begin by applying the first step of Fact 1:

$$a_{n+1}x^{n+1} - 2a_n x^{n+1} = x^{n+1},$$
$$\sum_{n=0}^{\infty} a_{n+1}x^{n+1} - 2\sum_{n=0}^{\infty} a_n x^{n+1} = \sum_{n=0}^{\infty} x^{n+1}.$$

Then apply the second step of Fact 1:

$$\sum_{n=0}^{\infty} a_{n+1}x^{n+1} - 2x\sum_{n=0}^{\infty} a_n x^n = x\sum_{n=0}^{\infty} x^n,$$
$$(f(x) - a_0) - 2xf(x) = \tfrac{x}{1-x},$$
$$(f(x) - 0) - 2xf(x) = \tfrac{x}{1-x}.$$

Solving for $f(x)$ gives

$$f(x) = \tfrac{x}{(1-x)(1-2x)} = \tfrac{1}{1-2x} - \tfrac{1}{1-x} = \sum_{n=0}^{\infty}(2x)^n - \sum_{n=0}^{\infty} x^n = \sum_{n=0}^{\infty}(2^n - 1)x^n.$$

Since a_n is the coefficient of x^n in $f(x)$, $a_n = 2^n - 1$, $n \ge 0$.

2. To solve the nonhomogeneous second-order relation $a_{n+2} - 2a_{n+1} + a_n = 2^n$, $n \ge 0$, $a_0 = 1$, $a_1 = 2$, apply the first step of Fact 1:

$$a_{n+2}x^{n+2} - 2a_{n+1}x^{n+2} + a_n x^{n+2} = 2^n x^{n+2},$$
$$\sum_{n=0}^{\infty} a_{n+2}x^{n+2} - 2\sum_{n=0}^{\infty} a_{n+1}x^{n+2} + \sum_{n=0}^{\infty} a_n x^{n+2} = \sum_{n=0}^{\infty} 2^n x^{n+2}.$$

The second step of Fact 1 produces

$$\sum_{n=0}^{\infty} a_{n+2}x^{n+2} - 2x\sum_{n=0}^{\infty} a_{n+1}x^{n+1} + x^2\sum_{n=0}^{\infty} a_n x^n = x^2\sum_{n=0}^{\infty}(2x)^n,$$
$$[f(x) - a_0 - a_1x] - 2x[f(x) - a_0] + x^2f(x) = \tfrac{x^2}{1-2x},$$
$$[f(x) - 1 - 2x] - 2x[f(x) - 1] + x^2f(x) = \tfrac{x^2}{1-2x}.$$

Solving for $f(x)$ gives

$$f(x) = \tfrac{1}{1-2x} = \sum_{n=0}^{\infty}(2x)^n = \sum_{n=0}^{\infty} 2^n x^n.$$

Thus $a_n = 2^n$, $n \ge 0$, is the solution of the given recurrence relation.

3. Fact 2 can be used to solve the system of recurrence relations

$$a_{n+1} = 2a_n - b_n + 2$$
$$b_{n+1} = -a_n + 2b_n - 1$$

for $n \ge 0$, with $a_0 = 0$ and $b_0 = 1$. Multiplying by x^{n+1} and summing yields

$$\sum_{n=0}^{\infty} a_{n+1}x^{n+1} = 2x\sum_{n=0}^{\infty} a_n x^n - x\sum_{n=0}^{\infty} b_n x^n + 2x\sum_{n=0}^{\infty} x^n$$
$$\sum_{n=0}^{\infty} b_{n+1}x^{n+1} = -x\sum_{n=0}^{\infty} a_n x^n + 2x\sum_{n=0}^{\infty} b_n x^n - x\sum_{n=0}^{\infty} x^n.$$

These two equations can be rewritten in terms of the generating functions $f(x) = \sum_{n=0}^{\infty} a_n x^n$ and $g(x) = \sum_{n=0}^{\infty} b_n x^n$ as

$$\begin{aligned} f(x) - a_0 &= 2xf(x) - xg(x) + 2x\tfrac{1}{1-x} \\ g(x) - b_0 &= -xf(x) + 2xg(x) - x\tfrac{1}{1-x}. \end{aligned}$$

Solving this system (with $a_0 = 0$, $b_0 = 1$) produces

$$\begin{aligned} f(x) &= \tfrac{x(1-2x)}{(1-x)^2(1-3x)} = -\tfrac{3}{4}\tfrac{1}{1-x} + \tfrac{1}{2}\tfrac{1}{(1-x)^2} + \tfrac{1}{4}\tfrac{1}{(1-3x)} \\ &= -\tfrac{3}{4}\sum_{n=0}^{\infty} x^n + \tfrac{1}{2}\sum_{n=0}^{\infty} \tbinom{-2}{n} x^n + \tfrac{1}{4}\sum_{n=0}^{\infty} (3x)^n \\ &= -\tfrac{3}{4}\sum_{n=0}^{\infty} x^n + \tfrac{1}{2}\sum_{n=0}^{\infty} \tbinom{n+1}{n} x^n + \tfrac{1}{4}\sum_{n=0}^{\infty} 3^n x^n \end{aligned}$$

and

$$\begin{aligned} g(x) &= \tfrac{1-4x+2x^2}{(1-x)^2(1-3x)} = \tfrac{3}{4}\tfrac{1}{1-x} + \tfrac{1}{2}\tfrac{1}{(1-x)^2} - \tfrac{1}{4}\tfrac{1}{(1-3x)} \\ &= \tfrac{3}{4}\sum_{n=0}^{\infty} x^n + \tfrac{1}{2}\sum_{n=0}^{\infty} \tbinom{n+1}{n} x^n - \tfrac{1}{4}\sum_{n=0}^{\infty} 3^n x^n. \end{aligned}$$

It then follows that

$$\begin{aligned} a_n &= -\tfrac{3}{4} + \tfrac{1}{2}(n+1) + \tfrac{1}{4}(3^n), \quad n \geq 0 \\ b_n &= \tfrac{3}{4} + \tfrac{1}{2}(n+1) - \tfrac{1}{4}(3^n), \quad n \geq 0. \end{aligned}$$

3.3.5 DIVIDE-AND-CONQUER RELATIONS

Certain algorithms proceed by breaking up a given problem into subproblems of nearly equal size; solutions to these subproblems are then combined to produce a solution to the original problem. Analysis of such "divide-and-conquer" algorithms results in special types of recurrence relations that can be solved both exactly and asymptotically.

Definitions:

The ***time-complexity function*** $f(n)$ for an algorithm gives the (maximum) number of operations required to solve any instance of size n. The function $f(n)$ is ***monotone increasing*** if $m < n \Rightarrow f(m) \leq f(n)$ where m and n are positive integers.

A ***recursive divide-and-conquer algorithm*** splits a given problem of size $n = b^k$ into a subproblems of size $\frac{n}{b}$ each. It requires (at most) $h(n)$ operations to create the subproblems and subsequently combine their solutions.

Let $S = S_b$ be the set of integers $\{1, b, b^2, \ldots\}$ and let $\mathcal{Z}^+$ be the set of positive integers.

If $f(n)$ and $g(n)$ are functions on $\mathcal{Z}^+$, then g ***dominates*** f ***on*** S, written $f \in O(g)$ on S, if there are positive constants $A \in \mathcal{R}$, $k \in \mathcal{Z}^+$ such that $|f(n)| \leq A|g(n)|$ holds for all $n \in S$ with $n \geq k$.

Facts:

1. The time-complexity function $f(n)$ of a recursive divide-and-conquer algorithm is defined for $n \in S$ and satisfies the recurrence relation

$$\begin{aligned} &f(1) = c, \\ &f(n) = af(n/b) + h(n), \quad \text{for } n = b^k,\ k \geq 1, \end{aligned}$$

where $a, b, c \in \mathcal{Z}^+$ and $b \geq 2$.

2. *Solving $f(n) = af(n/b) + c$, $f(1) = c$*:

- If $a = 1$: $f(n) = c(\log_b n + 1)$ for $n \in S$. Thus $f \in O(\log_b n)$ on S. If, in addition, $f(n)$ is monotone increasing, then $f \in O(\log_b n)$ on $\mathcal{Z}^+$.
- If $a \geq 2$: $f(n) = c(an^{\log_b a} - 1)/(a - 1)$ for $n \in S$. Thus $f \in O(n^{\log_b a})$ on S. If, in addition, $f(n)$ is monotone increasing, then $f \in O(n^{\log_b a})$ on $\mathcal{Z}^+$.

3. Let $f(n)$ be any function satisfying the inequality relations

$$\begin{aligned} &f(1) \leq c, \\ &f(n) \leq af(n/b) + c, \quad \text{for } \; n = b^k, \; k \geq 1, \end{aligned}$$

where $a, b, c \in \mathcal{Z}^+$ and $b \geq 2$.

- If $a = 1$: $f \in O(\log_b n)$ on S. If, in addition, $f(n)$ is monotone increasing, then $f \in O(\log_b n)$ on $\mathcal{Z}^+$.
- If $a \geq 2$: $f \in O(n^{\log_b a})$ on S. If, in addition, $f(n)$ is monotone increasing, then $f \in O(n^{\log_b a})$ on $\mathcal{Z}^+$.

4. *Solving for a monotone increasing $f(n)$ where $f(n) = af(n/b) + rn^d$ ($n = b^k$, $k \geq 1$), $f(1) = c$, where $a, b, c, d \in \mathcal{Z}^+$, $b \geq 2$, and r is a positive real number*:

- If $a < b^d$: $f \in O(n^d)$ on $\mathcal{Z}^+$.
- If $a = b^d$: $f \in O(n^d \log_b n)$ on $\mathcal{Z}^+$.
- If $a > b^d$: $f \in O(n^{\log_b a})$ on $\mathcal{Z}^+$.

The same asymptotic results hold if inequalities $\leq$ replace equalities in the given recurrence relation.

Examples:

1. If $f(n)$ satisfies the recurrence relation $f(n) = f(\frac{n}{2}) + 3$, $n \in S_2$, $f(1) = 3$, then Fact 2 gives $f(n) = 3(\log_2 n + 1)$. Thus $f \in O(\log_2 n)$ on S_2.

2. If $f(n)$ satisfies the recurrence relation $f(n) = 4f(\frac{n}{3}) + 7$, $n \in S_3$, $f(1) = 7$, then Fact 2 gives $f(n) = 7(4n^{\log_3 4} - 1)/3$. Thus $f \in O(n^{\log_3 4})$ on S_3.

3. *Binary search*: The binary search algorithm (§18.2.3) is a recursive procedure to search for a specified value in an ordered list of n items. Its complexity function satisfies $f(n) = f(\frac{n}{2}) + 2$, $n \in S_2$, $f(1) = 2$. Since the complexity function $f(n)$ is monotone increasing in the list size n, Fact 2 shows that $f \in O(\log_2 n)$.

4. *Merge sort*: The merge sort algorithm (§18.3.4) is a recursive procedure for sorting the n elements of a list. It repeatedly divides a given list into two nearly equal sublists, sorts those sublists, and combines the sorted sublists. Its complexity function satisfies $f(n) = 2f(\frac{n}{2}) + (n-1)$, $n \in S_2$, $f(1) = 0$. Since $f(n)$ is monotone increasing and satisfies the inequality relation $f(n) \leq 2f(\frac{n}{2}) + n$, Fact 4 gives $f \in O(n \log_2 n)$.

5. *Matrix multiplication*: The Strassen algorithm is a recursive procedure for multiplying two $n \times n$ matrices (see §6.3.3). One version of this algorithm requires seven multiplications of $\frac{n}{2} \times \frac{n}{2}$ matrices and 15 additions of $\frac{n}{2} \times \frac{n}{2}$ matrices. Consequently, its complexity function satisfies $f(n) = 7f(\frac{n}{2}) + 15n^2/4$, $n \in S_2$, $f(1) = 1$. From the third part of Fact 4, $f \in O(n^{\log_2 7})$ on $\mathcal{Z}^+$. This algorithm requires approximately $O(n^{2.81})$ operations to multiply $n \times n$ matrices, compared to $O(n^3)$ for the standard method.

3.4 FINITE DIFFERENCES

The difference and antidifference operators are the discrete analogues of ordinary differentiation and antidifferentiation. Difference methods can be used for curve-fitting and for solving recurrence relations.

3.4.1 THE DIFFERENCE OPERATOR

The difference operator plays a role in combinatorial modeling analogous to that of the derivative operator in continuous analysis.

Definitions:

Let $f\colon \mathcal{N} \to \mathcal{R}$.

The ***difference operator*** $\Delta f(x) = f(x+1) - f(x)$ is the discrete analogue of the differentiation operator.

The ***kth difference*** of f is the operator $\Delta^k f(x) = \Delta^{k-1} f(x+1) - \Delta^{k-1} f(x)$, for $k \geq 1$, with $\Delta^0 f = f$.

The ***shift operator*** E is defined by $Ef(x) = f(x+1)$.

The ***harmonic sum*** $H_n = \sum_{i=1}^{n} \frac{1}{i}$ is the discrete analogue of the natural logarithm (§3.1.7).

Note: Most of the results stated in this subsection are also valid for functions on non-discrete domains. The functional notation that is used for most of this subsection, instead of the more usual subscript notation for sequences, makes the results easier to read and helps underscore the parallels between discrete and ordinary calculus.

Facts:

1. *Linearity*: $\Delta(\alpha f + \beta g) = \alpha \Delta f + \beta \Delta g$, for all constants α and β.

2. *Product rule*: $\Delta(f(x)g(x)) = (Ef(x))\Delta g(x) + (\Delta f(x))g(x)$. This is analogous to the derivative formula for the product of functions.

3. $\Delta^m x^n = 0$, for $m > n$, and $\Delta^n x^n = n!$.

4. $\Delta^n f(x) = \sum\limits_{k=0}^{n} (-1)^k \binom{n}{k} f(x+n-k)$.

5. $f(x+n) = \sum\limits_{k=0}^{n} \binom{n}{k} \Delta^k f(x)$.

6. *Leibniz's theorem*: $\Delta^n (f(x)g(x)) = \sum\limits_{k=0}^{n} \binom{n}{k} \Delta^k f(x) \Delta^{n-k} g(x+k)$.

7. *Quotient rule*: $\Delta\left(\frac{f(x)}{g(x)}\right) = \frac{g(x)\Delta f(x) - f(x)\Delta g(x)}{g(x)g(x+1)}$.

8. The shift operator E satisfies $\Delta f = Ef - f$, written equivalently as $E = 1 + \Delta$.

9. $E^n f(x) = f(x+n)$.

10. The equation $\Delta C(x) = 0$ implies that C is periodic with period 1. Moreover, if the domain is restricted to the integers (e.g., if $C(n)$ is a sequence), then C is constant.

Examples:

1. If $f(x) = x^3$ then $\Delta f(x) = (x+1)^3 - x^3 = 3x^2 + 3x + 1$.

2. The following table gives formulas for the differences of some important functions. In this table, the notation $x^{\underline{n}}$ refers to the nth falling power of x (§3.4.2).

$f(x)$	$\Delta f(x)$
$\binom{x}{n}$	$\binom{x}{n-1}$
$(x+a)^{\underline{n}}$	$n(x+a)^{\underline{n-1}}$
x^n	$\binom{n}{1}x^{n-1} + \binom{n}{2}x^{n-2} + \cdots + 1$
a^x	$(a-1)a^x$
H_x	$x^{\underline{-1}} = \frac{1}{x+1}$
$\sin x$	$2\sin(\frac{1}{2})\cos(x+\frac{1}{2})$
$\cos x$	$-2\sin(\frac{1}{2})\sin(x+\frac{1}{2})$

3. $\Delta^2 f(x) = f(x+2) - 2f(x+1) + f(x)$, from Fact 4.

4. $f(x+3) = f(x) + 3\Delta f(x) + 3\Delta^2 f(x) + \Delta^3 f(x)$, from Fact 5.

5. The shift operator can be used to find the exponential generating function (§3.2.2) for the sequence $\{a_k\}$, where a_k is a polynomial in variable k of degree n.

$$\begin{aligned}\sum_{k=0}^{\infty} \frac{a_k x^k}{k!} = \sum_{k=0}^{\infty} \frac{E^k(a_0)x^k}{k!} &= \left(\sum_{k=0}^{\infty} \frac{x^k E^k}{k!}\right) a_0 \\ &= e^{xE}a_0 = e^{x(1+\Delta)}a_0 = e^x e^{x\Delta} a_0 \\ &= e^x\left(a_0 + \frac{x\Delta a_0}{1!} + \frac{x^2\Delta^2 a_0}{2!} + \cdots + \frac{x^n \Delta^n a_0}{n!}\right).\end{aligned}$$

For example, if $a_k = k^2 + 1$ then $\sum_{k=0}^{\infty} \frac{(k^2+1)x^k}{k!} = e^x(1 + x + x^2)$.

3.4.2 CALCULUS OF DIFFERENCES: FALLING AND RISING POWERS

Falling powers provide a natural analogue between the calculus of finite sums and differences and the calculus of integrals and derivatives. Stirling numbers provide a means of expressing ordinary powers in terms of falling powers and vice versa.

Definitions:

The ***nth falling power*** of x, written $x^{\underline{n}}$, is the discrete analogue of exponentiation and is defined by

$$\begin{aligned} x^{\underline{n}} &= x(x-1)(x-2)\ldots(x-n+1) \\ x^{\underline{-n}} &= \frac{1}{(x+1)(x+2)\ldots(x+n)} \\ x^{\underline{0}} &= 1. \end{aligned}$$

The ***nth rising power*** of x, written $x^{\overline{n}}$, is defined by

$$\begin{aligned} x^{\overline{n}} &= x(x+1)(x+2)\ldots(x+n-1), \\ x^{\overline{-n}} &= \frac{1}{(x-n)(x-n+1)\ldots(x-1)}, \\ x^{\overline{0}} &= 1. \end{aligned}$$

Facts:

1. *Conversion between falling and rising powers*:

$$\begin{aligned} x^{\underline{n}} &= (-1)^n(-x)^{\overline{n}} = (x-n+1)^{\overline{n}} = \tfrac{1}{(x+1)^{\overline{-n}}}\ , \\ x^{\overline{n}} &= (-1)^n(-x)^{\underline{n}} = (x+n-1)^{\underline{n}} = \tfrac{1}{(x-1)^{\underline{-n}}}\ , \\ x^{\underline{-n}} &= \tfrac{1}{(x+1)^{\overline{n}}}, \\ x^{\overline{-n}} &= \tfrac{1}{(x-1)^{\underline{n}}}\ . \end{aligned}$$

2. *Laws of exponents*:

$$\begin{aligned} x^{\underline{m+n}} &= x^{\underline{m}}(x-m)^{\underline{n}}\ , \\ x^{\overline{m+n}} &= x^{\overline{m}}(x+m)^{\overline{n}}\ . \end{aligned}$$

3. *Binomial theorem*: $(x+y)^{\underline{n}} = \binom{n}{0}x^{\underline{n}} + \binom{n}{1}x^{\underline{n-1}}y^{\underline{1}} + \cdots + \binom{n}{n}y^{\underline{n}}$.

4. The action of the difference operator on falling powers is analogous to the action of the derivative on ordinary powers: $\Delta x^{\underline{n}} = nx^{\underline{n-1}}$.

5. There is no chain rule for differences, but the binomial theorem implies the rule

$$\Delta(x+a)^{\underline{n}} = n(x+a)^{\underline{n-1}}\ .$$

6. *Newton's theorem*: If $f(x)$ is a polynomial of degree n, then

$$f(x) = \sum_{k=0}^{n} \tfrac{\Delta^k f(0)}{k!}x^{\underline{k}}\ .$$

This is an analogue of *Maclaurin's theorem*.

7. If $f(x) = x^n$ then $\Delta^k f(0) = \left\{ {n \atop k} \right\} \cdot k!$, where $\left\{ {n \atop k} \right\}$ is a Stirling subset number (§2.5.2).

8. Falling powers can be expressed in terms of ordinary powers using Stirling cycle numbers (§2.5.2):

$$x^{\underline{n}} = \sum_{k=1}^{n} \left[{n \atop k} \right](-1)^{n-k}x^k.$$

9. Rising powers can be expressed in terms of ordinary powers using Stirling cycle numbers (§2.5.2):

$$x^{\overline{n}} = \sum_{k=1}^{n} \left[{n \atop k} \right]x^k.$$

10. Ordinary powers can be expressed in terms of falling or rising powers using Stirling subset numbers (§2.5.2):

$$x^n = \sum_{k=1}^{n} \left\{ {n \atop k} \right\}x^{\underline{k}} = \sum_{k=1}^{n} \left\{ {n \atop k} \right\}(-1)^{n-k}x^{\overline{k}}.$$

Examples:

1. Fact 8, together with Fact 3 of §2.5.2, gives

$$\begin{aligned} x^{\underline{0}} &= x^0, \\ x^{\underline{1}} &= x^1, \\ x^{\underline{2}} &= x^2 - x^1, \\ x^{\underline{3}} &= x^3 - 3x^2 + 2x^1, \\ x^{\underline{4}} &= x^4 - 6x^3 + 11x^2 - 6x^1. \end{aligned}$$

2. Fact 10, together with Fact 4 of §2.5.2, gives

$$\begin{aligned}
x^0 &= x^{\underline{0}}\ ,\\
x^1 &= x^{\underline{1}}\ ,\\
x^2 &= x^{\underline{2}} + x^{\underline{1}}\ ,\\
x^3 &= x^{\underline{3}} + 3x^{\underline{2}} + x^{\underline{1}}\ ,\\
x^4 &= x^{\underline{4}} + 6x^{\underline{3}} + 7x^{\underline{2}} + x^{\underline{1}}\ .
\end{aligned}$$

3.4.3 DIFFERENCE SEQUENCES AND DIFFERENCE TABLES

New sequences can be obtained from a given sequence by repeatedly applying the difference operator.

Definitions:

The ***difference sequence*** for the sequence $A = \{\, a_j \mid j = 0, 1, \ldots\}$ is the sequence $\Delta A = \{\, a_{j+1} - a_j \mid j = 0, 1, \ldots\}$.

The ***kth difference sequence*** for $f\colon \mathcal{N} \to \mathcal{R}$ is given by $\Delta^k f(0), \Delta^k f(1), \Delta^k f(2), \ldots$.

The ***difference table*** for $f\colon \mathcal{N} \to \mathcal{R}$ is the table T_f whose kth row is the kth difference sequence for f. That is, $T_f[k, l] = \Delta^k f(l) = \Delta^{k-1} f(l+1) - \Delta^{k-1} f(l)$.

Facts:

1. The leftmost column of a difference table completely determines the entire table, via Newton's theorem (Fact 6, §3.4.2).

2. The difference table of an nth degree polynomial consists of $n + 1$ nonzero rows followed by all zero rows.

Examples:

1. If $A = 0, 1, 4, 9, 16, 25, \ldots$ is the sequence of squares of integers, then its difference sequence is $\Delta A = 1, 3, 5, 7, 9, \ldots$. Observe that $\Delta(x^2) = 2x + 1$.

2. The difference table for $x^{\underline{3}}$ is given by

	0	1	2	3	4	5	$\cdots$
$\Delta^0 x^{\underline{3}} = x^{\underline{3}}$	0	0	0	6	24	60	$\cdots$
$\Delta^1 x^{\underline{3}} = 3x^{\underline{2}}$	0	0	6	18	36	$\cdots$	
$\Delta^2 x^{\underline{3}} = 6x^{\underline{1}}$	0	6	12	18	$\cdots$		
$\Delta^3 x^{\underline{3}} = 6$	6	6	6	$\cdots$			
$\Delta^4 x^{\underline{3}} = 0$	0	0	$\cdots$				

3. The difference table for x^3 is given by

	0	1	2	3	4	5	$\cdots$
$\Delta^0 x^3 = x^3$	0	1	8	27	64	125	$\cdots$
$\Delta^1 x^3 = 3x^2 + 3x + 1$	1	7	19	37	61	$\cdots$	
$\Delta^2 x^3 = 6x + 6$	6	12	18	24	$\cdots$		
$\Delta^3 x^3 = 6$	6	6	6	$\cdots$			
$\Delta^4 x^3 = 0$	0	0	$\cdots$				

4. The difference table for 3^x is given by

	0	1	2	3	4	5	$\cdots$
$\Delta^0 3^x = 3^x$	1	3	9	27	81	243	$\ldots$
$\Delta^1 3^x = 2 \cdot 3^x$	2	6	18	54	162	$\ldots$	
$\Delta^2 3^x = 4 \cdot 3^x$	4	12	36	108	$\ldots$		
$\Delta^3 3^x = 8 \cdot 3^x$	8	24	72	$\ldots$			
$\Delta^4 3^x = 16 \cdot 3^x$	16	48	$\ldots$				
$\vdots$	$\vdots$						
$\Delta^k 3^x = 2^k 3^x$							

5. *Application to curve-fitting*: Find the polynomial $p(x)$ of smallest degree that passes through the points $(0,5), (1,5), (2,3), (3,5), (4,17), (5,45)$. The difference table for the sequence $5, 5, 3, 5, 17, 45$ is

5	5	3	5	17	45	$\ldots$
0	-2	2	12	28	$\ldots$	
-2	4	10	16	$\ldots$		
6	6	6	$\ldots$			
0	0	$\ldots$				

Newton's theorem shows that the polynomial of smallest degree is $p(x) = 5 - x^{\underline{2}} + x^{\underline{3}} = x^3 - 4x^2 + 3x + 5$.

3.4.4 DIFFERENCE EQUATIONS

Difference equations are analogous to differential equations and many of the techniques are as fully developed. Difference equations provide a way to solve recurrence relations.

Definitions:

A ***difference equation*** is an equation involving the difference operator and/or higher-order differences of an unknown function.

An ***antidifference*** of the function f is any function g such that $\Delta g = f$. The notation $\Delta^{-1} f$ denotes any such function.

Facts:

1. Any recurrence relation (§3.3) can be expressed as a difference equation, and vice versa, by using Facts 4 and 5 of §3.4.1.

2. The solution to a recurrence relation can sometimes be easily obtained by converting it to a difference equation and applying difference methods.

Examples:

1. To find an antidifference of $10 \cdot 3^x$, refer to the table given in Example 2 of §3.4.1: $\Delta^{-1}(10 \cdot 3^x) = 5\Delta^{-1}(2 \cdot 3^x) = 5 \cdot 3^x + C$. (Also see Fact 5 of §3.5.3.)

2. To find an antidifference of $3x$, first express x as $x^{\underline{1}}$ and then use the table found in Example 2 of §3.4.1: $\Delta^{-1} 3x = 3\Delta^{-1} x^{\underline{1}} = \frac{3}{2} x^{\underline{2}} + C = \frac{3}{2} x(x-1) + C$.

3. To find an antidifference of x^2, express x^2 as $x^{\underline{2}} + x^{\underline{1}}$ and then use the table found in Example 2 of §3.4.1: $\Delta^{-1}x^2 = \Delta^{-1}(x^{\underline{2}} + x^{\underline{1}}) = \Delta^{-1}x^{\underline{2}} + \Delta^{-1}x^{\underline{1}} = \frac{1}{3}x^{\underline{3}} + \frac{1}{2}x^{\underline{2}} + C = \frac{1}{3}x(x-1)(x-2) + \frac{1}{2}x(x-1) + C$.

4. The following are examples of difference equations:

$$\Delta^3 f(x) + x^4\Delta^2 f(x) - f(x) = 0,$$
$$\Delta^3 f(x) + f(x) = x^2.$$

5. To solve the recurrence relation $a_{n+1} = a_n + 5^n$, $n \geq 0$, with $a_0 = 2$, first note that $\Delta a_n = 5^n$. Thus $a_n = \Delta^{-1}5^n = \frac{1}{4}(5^n) + C$. The initial condition $a_0 = 2$ now implies that $a_n = \frac{1}{4}(5^n + 7)$.

6. To solve the equation $a_{n+1} = (na_n + n)/(n+1)$, $n \geq 1$, the recurrence relation is first rewritten as $(n+1)a_{n+1} - na_n = n$, which is equivalent to $\Delta(na_n) = n$. Thus $na_n = \Delta^{-1}n = \frac{1}{2}n^{\underline{2}} + C$, which implies that $a_n = \frac{1}{2}(n-1) + C(\frac{1}{n})$.

7. To solve $a_n = 2a_{n-1} - a_{n-2} + 2^{n-2} + n - 2$, $n \geq 2$, with $a_0 = 4$, $a_1 = 5$, the recurrence relation is rewritten as $a_{n+2} - 2a_{n+1} + a_n = 2^n + n$, $n \geq 0$. Now, by applying Fact 4 of §3.4.1, the left-hand side may be replaced by $\Delta^2 a_n$. If the antidifference operator is applied twice to the resulting difference equation and the initial conditions are substituted, the solution obtained is

$$a_n = 2^n + \tfrac{1}{6}n^{\underline{3}} + c_1 n + c_2 = 2^n + \tfrac{1}{6}n(n-1)(n-2) + 3.$$

3.5 FINITE SUMS AND SUMMATION

Finite sums arise frequently in combinatorial mathematics and in the analysis of running times of algorithms. There are a few basic rules for transforming sums into possibly more tractable equivalent forms, and there is a calculus for evaluating these standard forms.

3.5.1 SIGMA NOTATION

A complex form of symbolic representation of discrete sums using the uppercase Greek letter Σ (sigma) was introduced by Joseph Fourier in 1820 and has evolved into several variations.

Definitions:

The ***sigma expression*** $\sum_{i=a}^{b} f(i)$ has the value $f(a) + f(a+1) + \cdots + f(b-1) + f(b)$ if $a \leq b$ $(a, b \in \mathcal{Z})$, and 0 otherwise. In this expression, i is the ***index of summation*** or ***summation variable***, which ranges from the ***lower limit*** a to the ***upper limit*** b. The interval $[a, b]$ is the ***interval of summation***, and $f(i)$ is a ***term*** or ***summand*** of the summation.

A sigma expression $S_n = \sum_{i=0}^{n} f(i)$ is in ***standardized form*** if the lower limit is zero and the upper limit is an integer-valued expression.

A ***sigma expression*** $\sum_{k\in K} g(k)$ ***over the set*** K has as its value the sum of all the values $g(k)$, where $k \in K$.

A ***closed form*** for a sigma expression with an indefinite number of terms is an algebraic expression with a fixed number of terms, whose value equals the sum.

A ***partial sum*** of the (standardized) sigma expression $S_n = \sum_{i=0}^{n} f(i)$ is the sigma expression $S_k = \sum_{i=0}^{k} f(i)$, where $0 \le k \le n$.

An ***iterated sum*** or ***multiple sum*** is an expression with two or more sigmas, as exemplified by the double sum $\sum_{i=c}^{d} \sum_{j=a}^{b} f(i,j)$. Evaluation proceeds from the innermost sigma outward.

A lower or upper limit for an inner sum of an iterated sum is ***dependent*** if it depends on an outer variable. Otherwise, that limit is ***independent***.

Examples:

1. The sum $f(1) + f(2) + f(3) + f(4) + f(5)$ may be represented as $\sum_{i=1}^{5} f(i)$.

2. Sometimes the summand is written as an expression, such as $\sum_{n=1}^{50}(n^2 + n)$, which means the same as $\sum_{n=1}^{50} f(n)$, where $f(n) = n^2 + n$. Brackets or parentheses can be used to distinguish what is in the summand of such an "anonymous function" from whatever is written to the immediate right of the sigma expression. They may be omitted when such a summand is very simple.

3. Sometimes the property defining the indexing set is written as part of the Σ, as in the expressions $\sum_{1 \le k \le n} a_k$ or $\sum_{k \in K} b_k$.

4. The right-hand side of the equation $\sum_{j=0}^{n} x^j = \frac{x^{n+1}-1}{x-1}$ is a closed form for the sigma expression on the left-hand side.

5. The operational meaning of the multiple sum with independent limits $\sum_{i=1}^{3} \sum_{j=2}^{4} \frac{i}{j}$ is first to expand the inner sum, obtaining the single sum $\sum_{i=1}^{3} \left[\frac{i}{2} + \frac{i}{3} + \frac{i}{4}\right]$. Expansion of the outer sum then yields $\left[\frac{1}{2} + \frac{1}{3} + \frac{1}{4}\right] + \left[\frac{2}{2} + \frac{2}{3} + \frac{2}{4}\right] + \left[\frac{3}{2} + \frac{3}{3} + \frac{3}{4}\right] = \frac{13}{2}$.

6. The multiple sum with dependent limits $\sum_{i=1}^{3} \sum_{j=i}^{4} \frac{i}{j}$ is evaluated by first expanding the inner sum, obtaining $\left[\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4}\right] + \left[\frac{2}{2} + \frac{2}{3} + \frac{2}{4}\right] + \left[\frac{3}{3} + \frac{3}{4}\right] = 6$.

3.5.2 ELEMENTARY TRANSFORMATION RULES FOR SUMS

Sums can be transformed using a few simple rules. A well-chosen sequence of transformations often simplifies evaluation.

Facts:

1. *Distributivity rule*: $\sum\limits_{k \in K} ca_k = c \sum\limits_{k \in K} a_k$, for any constant c.

2. *Associativity rule*: $\sum\limits_{k \in K} (a_k + b_k) = \sum\limits_{k \in K} a_k + \sum\limits_{k \in K} b_k$.

3. *Rearrangement rule*: $\sum\limits_{k \in K} a_k = \sum\limits_{k \in K} a_{\rho(k)}$, if ρ is a permutation of the integers in K.

4. *Telescoping for sequences*: For any sequence $\{\, a_j \mid j = 0, 1, \ldots \}$, $\sum\limits_{i=m}^{n} (a_{i+1} - a_i) = a_{n+1} - a_m$.

5. *Telescoping for functions*: For any function $f \colon \mathcal{N} \to \mathcal{R}$, $\sum\limits_{i=m}^{n} \Delta f(i) = f(n+1) - f(m)$.

6. *Perturbation method*: Given a standardized sum $S_n = \sum_{i=0}^{n} f(i)$, form the equation

$$\sum_{i=0}^{n} f(i) + f(n+1) = f(0) + \sum_{i=1}^{n+1} f(i) = f(0) + \sum_{i=0}^{n} f(i+1).$$

Algebraic manipulation often leads to a closed form for S_n.

7. *Interchanging independent indices of a double sum*: When the lower and upper limits of the inner variable of a double sum are independent of the outer variable, the order of summation can be changed, simply by swapping the inner sigma, limits and all, with the outer sigma. That is,

$$\sum_{i=c}^{d}\sum_{j=a}^{b} f(i,j) = \sum_{j=a}^{b}\sum_{i=c}^{d} f(i,j).$$

8. *Interchanging dependent indices of a double sum*: When either the lower or upper limit of the inner variable j of a double sum of an expression $f(i,j)$ is dependent on the outer variable i, the order of summation can still be changed by swapping the inner sum with the outer sum. However, the limits of the new inner variable i must be written as functions of the new outer variable j so that the entire set of pairs (i,j) over which $f(i,j)$ is summed is the same as before. One particular case of interest is the interchange

$$\sum_{i=1}^{n}\sum_{j=i}^{n} f(i,j) = \sum_{j=1}^{n}\sum_{i=1}^{j} f(i,j).$$

Examples:

1. The following summation can be evaluated using Fact 4 (telescoping for sequences):

$$\sum_{i=1}^{n} \frac{1}{i(i+1)} = -\sum_{i=1}^{n}\left(\frac{1}{i+1} - \frac{1}{i}\right) = 1 - \frac{1}{n+1}.$$

2. Evaluate $S_n = \sum_{i=0}^{n} x^i$, using the perturbation method.

$$\sum_{i=0}^{n} x^i + x^{n+1} = x^0 + \sum_{i=1}^{n+1} x^i = 1 + x\sum_{i=1}^{n+1} x^{i-1},$$
$$S_n + x^{n+1} = 1 + x\sum_{i=0}^{n} x^i = 1 + xS_n,$$

giving $S_n = \frac{x^{n+1}-1}{x-1}$.

3. Evaluate $S_n = \sum_{i=0}^{n} i2^i$, using the perturbation method.

$$\sum_{i=0}^{n} i2^i + (n+1)2^{n+1} = 0\cdot 2^0 + \sum_{i=1}^{n+1} i2^i = \sum_{i=0}^{n}(i+1)2^{i+1},$$
$$S_n + (n+1)2^{n+1} = 2\sum_{i=0}^{n} i2^i + 2\sum_{i=0}^{n} 2^i = 2S_n + 2(2^{n+1}-1),$$

giving $S_n = (n+1)2^{n+1} - 2(2^{n+1}-1) = (n-1)2^{n+1} + 2$.

4. Interchange independent indices of a double sum:

$$\sum_{i=1}^{3}\sum_{j=2}^{4} \frac{i}{j} = \sum_{j=2}^{4}\sum_{i=1}^{3} \frac{i}{j} = \sum_{j=2}^{4}\left[\frac{1}{j} + \frac{2}{j} + \frac{3}{j}\right] = \sum_{j=2}^{4} \frac{6}{j} = 6\sum_{j=2}^{4} \frac{1}{j} = 6\left[\frac{1}{2} + \frac{1}{3} + \frac{1}{4}\right] = \frac{13}{2}.$$

5. Interchange dependent indices of a double sum:

$$\sum_{i=1}^{3}\sum_{j=i}^{3}\frac{i}{j}=\sum_{j=1}^{3}\sum_{i=1}^{j}\frac{i}{j}=\sum_{j=1}^{3}\frac{1}{j}\sum_{i=1}^{j}i=\frac{1}{1}\cdot 1+\frac{1}{2}\cdot 3+\frac{1}{3}\cdot 6=\frac{9}{2}.$$

3.5.3 ANTIDIFFERENCES AND SUMMATION FORMULAS

Some standard combinatorial functions analogous to polynomials and exponential functions facilitate the development of a calculus of finite differences, analogous to the differential calculus of continuous mathematics. The *fundamental theorem of discrete calculus* is useful in deriving a number of summation formulas.

Definitions:

An ***antidifference*** of the function f is any function g such that $\Delta g = f$, where Δ is the difference operator (§3.4.1). The notation $\Delta^{-1}f$ denotes any such function.

The ***indefinite sum*** of the function f is the infinite family of all antidifferences of f. The notation $\sum f(x)\delta x + c$ is sometimes used for the indefinite sum to emphasize the analogy with integration.

Facts:

1. *Fundamental theorem of discrete calculus*:

$$\sum_{k=a}^{b} f(k)=\Delta^{-1}f(k)\Big|_{a}^{b+1}=\Delta^{-1}f(b+1)-\Delta^{-1}f(a).$$

Note: The upper evaluation point is one more than the upper limit of the sum.

2. *Linearity*: $\Delta^{-1}(\alpha f+\beta g)=\alpha\Delta^{-1}f+\beta\Delta^{-1}g$, for any constants α and β.

3. *Summation by parts*:

$$\sum_{i=a}^{b} f(i)\Delta g(i)=f(b+1)g(b+1)-f(a)g(a)-\sum_{i=a}^{b} g(i+1)\Delta f(i).$$

This result, which generalizes Fact 5 of §3.5.2, is a direct analogue of integration by parts in continuous analysis.

4. *Abel's transformation*:

$$\sum_{k=1}^{n} f(k)g(k)=f(n+1)\sum_{k=1}^{n} g(k)-\sum_{k=1}^{n}\Big(\Delta f(k)\sum_{r=1}^{k} g(r)\Big).$$

5. The following table gives the antidifferences of selected functions. In this table, H_x indicates the harmonic sum (§3.4.1), $x^{\underline{n}}$ is the nth falling power of x (§3.4.2), and $\left\{{n \atop k}\right\}$ is a Stirling subset number (§2.5.2).

$f(x)$	$\Delta^{-1}f(x)$	$f(x)$	$\Delta^{-1}f(x)$
$\binom{x}{n}$	$\binom{x}{n+1}$	$(x+a)^{\underline{n}}$	$\frac{(x+a)^{\underline{n+1}}}{n+1},\ n\neq -1$
$(x+a)^{\underline{-1}}$	H_{x+a}	a^x	$\frac{a^x}{(a-1)},\ a\neq 1$
a^x	$\frac{a^x}{(a-1)},\ a\neq 1$	xa^x	$\frac{a^x}{(a-1)}\left(x-\frac{a}{a-1}\right),\ a\neq 1$
x^n	$\sum_{k=1}^{n}\frac{\left\{{n \atop k}\right\}}{k+1}x^{\underline{k+1}}$	$(-1)^x$	$\frac{1}{2}(-1)^{x+1}$
$\sin x$	$\frac{-1}{2\sin(\frac{1}{2})}\cos(x-\frac{1}{2})$	$\cos x$	$\frac{1}{2\sin(\frac{1}{2})}\sin(x-\frac{1}{2})$

6. The following table gives finite sums of selected functions.

summation	*formula*	*summation*	*formula*
$\sum_{k=1}^{n} k^{\underline{m}}$	$\frac{(n+1)^{\underline{m+1}}}{m+1},\ m \neq -1$	$\sum_{k=1}^{n} k^{m}$	$\sum\limits_{j=1}^{m} \frac{\left\{ {m \atop j} \right\}(n+1)^{\underline{j+1}}}{j+1}$
$\sum_{k=0}^{n} a^{k}$	$\frac{a^{n+1}-1}{a-1},\ a \neq 1$	$\sum_{k=1}^{n} ka^{k}$	$\frac{(a-1)(n+1)a^{n+1}-a^{n+2}+a}{(a-1)^2},\ a \neq 1$
$\sum_{k=1}^{n} \sin k$	$\frac{\sin(\frac{n+1}{2})\sin(\frac{n}{2})}{\sin(\frac{1}{2})}$	$\sum_{k=1}^{n} \cos k$	$\frac{\cos(\frac{n+1}{2})\sin(\frac{n}{2})}{\sin(\frac{1}{2})}$

Examples:

1. $\sum\limits_{k=1}^{n} k^3 = \sum\limits_{k=1}^{n} (k^{\underline{1}} + 3k^{\underline{2}} + k^{\underline{3}}) = \left(\frac{k^{\underline{2}}}{2} + k^{\underline{3}} + \frac{k^{\underline{4}}}{4}\right)\Big|_1^{n+1} = \frac{n^2(n+1)^2}{4}.$

2. To evaluate $\sum\limits_{k=1}^{n} k(k+2)(k+3)$, first rewrite its summand:

$$\begin{aligned}
\sum_{k=1}^{n} k(k+2)(k+3) &= \Delta^{-1}[(k+1-1)(k+2)(k+3)]\Big|_1^{n+1} \\
&= \left[\Delta^{-1}(k+3)^{\underline{3}} - \Delta^{-1}(k+3)^{\underline{2}}\right]\Big|_1^{n+1} \\
&= \left[\frac{(k+3)^{\underline{4}}}{4} - \frac{(k+3)^{\underline{3}}}{3}\right]\Big|_1^{n+1} \\
&= \frac{(n+4)^{\underline{4}}}{4} - \frac{(n+4)^{\underline{3}}}{3} + 2 \\
&= \frac{(n+4)(n+3)(n+2)(3n-1)+24}{12}.
\end{aligned}$$

3. $\sum\limits_{k=1}^{n} k3^k = \Delta^{-1}(k3^k)\Big|_1^{n+1} = 3^k\left[\frac{k}{2} - \frac{3}{4}\right]\Big|_1^{n+1} = \frac{(2n-1)3^{n+1}+3}{4}.$

4. Summation by parts can be used to calculate $\sum_{j=0}^{n} jx^j$, using $f(j) = j$ and $\Delta g(j) = x^j$. Thus $g(j) = x^j/(x-1)$, and Fact 3 yields

$$\begin{aligned}
\sum_{j=0}^{n} jx^j &= \frac{(n+1)x^{n+1}}{(x-1)} - 0 - \sum_{j=0}^{n} \frac{x^{j+1}}{(x-1)} = \frac{(n+1)x^{n+1}}{(x-1)} - \frac{x}{x-1}\sum_{j=0}^{n} x^j \\
&= \frac{(n+1)x^{n+1}}{(x-1)} - \frac{x}{x-1}\,\frac{x^{n+1}-1}{(x-1)} = \frac{(n+1)(x-1)x^{n+1}-x^{n+2}+x}{(x-1)^2}.
\end{aligned}$$

5. Summation by parts also yields an antiderivative of $x3^x$:

$$\Delta^{-1}(x3^x) = \Delta^{-1}\left(x\Delta(\tfrac{1}{2}\cdot 3^x)\right) = \tfrac{1}{2}x3^x - \Delta^{-1}(\tfrac{1}{2}\cdot 3^{x+1}\cdot 1) = 3^x\left(\tfrac{x}{2} - \tfrac{3}{4}\right).$$

3.5.4 STANDARD SUMS

Many useful summation formulas are derivable by combinations of elementary manipulation and finite calculus. Such sums can be expressed in various ways, using different combinatorial coefficients. (See §3.1.8.)

Definition:

The ***power sum*** $S^k(n) = \sum_{j=1}^{n} j^k = 1^k + 2^k + 3^k + \cdots + n^k$ is the sum of the kth powers of the first n positive integers.

Facts:

1. $S^k(n)$ is a polynomial in n of degree $k+1$ with leading coefficient $1_{\overline{k+1}}$. The continuous analogue of this fact is the familiar $\int_a^b x^k dx = \frac{1}{k+1}(b^{k+1} - a^{k+1})$.

2. The power sum $S^k(n)$ can be expressed using the Bernoulli polynomials (§3.1.4) as

$$S^k(n) = \frac{1}{k+1}[B_{k+1}(n+1) - B_{k+1}(0)].$$

3. When $S^k(n)$ is expressed in terms of binomial coefficients with the second entry fixed at $k+1$, the coefficients are the Eulerian numbers (§3.1.5).

$$S^k(n) = \sum_{i=0}^{k-1} E(k,i)\tbinom{n+i+1}{k+1}.$$

4. When $S^k(n)$ is expressed in terms of binomial coefficients with the first entry fixed at $n+1$, the coefficients are products of factorials and Stirling subset numbers (§2.5.2).

$$S^k(n) = \sum_{i=1}^{k} i!\left\{{k \atop i}\right\}\tbinom{n+1}{i+1}.$$

5. Formulas for the power sums described in Facts 1, 3, and 4 are given in the next three tables, for small values of k.

summation	*formula*
$\sum_{j=1}^n j$	$\frac{1}{2}n(n+1)$
$\sum_{j=1}^n j^2$	$\frac{1}{6}n(n+1)(2n+1)$
$\sum_{j=1}^n j^3$	$\frac{1}{4}n^2(n+1)^2$
$\sum_{j=1}^n j^4$	$\frac{1}{30}n(n+1)(2n+1)(3n^2+3n-1)$
$\sum_{j=1}^n j^5$	$\frac{1}{12}n^2(n+1)^2(2n^2+2n-1)$
$\sum_{j=1}^n j^6$	$\frac{1}{42}n(n+1)(2n+1)(3n^4+6n^3-n^2-3n+1)$
$\sum_{j=1}^n j^7$	$\frac{1}{24}n^2(n+1)^2(3n^4+6n^3-n^2-4n+2)$
$\sum_{j=1}^n j^8$	$\frac{1}{90}n(n+1)(2n+1)(5n^6+15n^5+5n^4-15n^3-n^2+9n-3)$
$\sum_{j=1}^n j^9$	$\frac{1}{20}n^2(n+1)^2(2n^6+6n^5+n^4-8n^3+n^2+6n-3)$

summation	*formula*
$\sum_{j=1}^n j$	$\binom{n+1}{2}$
$\sum_{j=1}^n j^2$	$\binom{n+1}{3} + \binom{n+2}{3}$
$\sum_{j=1}^n j^3$	$\binom{n+1}{4} + 4\binom{n+2}{4} + \binom{n+3}{4}$
$\sum_{j=1}^n j^4$	$\binom{n+1}{5} + 11\binom{n+2}{5} + 11\binom{n+3}{5} + \binom{n+4}{5}$
$\sum_{j=1}^n j^5$	$\binom{n+1}{6} + 26\binom{n+2}{6} + 66\binom{n+3}{6} + 26\binom{n+4}{6} + \binom{n+5}{6}$

summation	*formula*
$\sum_{j=1}^n j$	$\binom{n+1}{2}$
$\sum_{j=1}^n j^2$	$\binom{n+1}{2} + 2\binom{n+1}{3}$
$\sum_{j=1}^n j^3$	$\binom{n+1}{2} + 6\binom{n+1}{3} + 6\binom{n+1}{4}$
$\sum_{j=1}^n j^4$	$\binom{n+1}{2} + 14\binom{n+1}{3} + 36\binom{n+1}{4} + 24\binom{n+1}{5}$
$\sum_{j=1}^n j^5$	$\binom{n+1}{2} + 30\binom{n+1}{3} + 150\binom{n+1}{4} + 240\binom{n+1}{5} + 120\binom{n+1}{6}$

Examples:

1. To find the third power sum $S^3(n) = \sum_{j=1}^{n} j^3$ via Fact 2, use the Bernoulli polynomial $B_4(x) = x^4 - 2x^3 + x^2 - \frac{1}{30}$ from the table found in §3.1.4. Thus

$$S^3(n) = \tfrac{1}{4}\big[B_4(x)\big]\Big|_0^{n+1} = \tfrac{(n+1)^4 - 2(n+1)^3 + (n+1)^2}{4} = \tfrac{n^2(n+1)^2}{4}.$$

2. Power sums can be found using antidifferences and Stirling numbers of both types. For example, to find $S^3(n) = \sum_{x=1}^{n} x^3$ first compute

$$\Delta^{-1}x^3 = \Delta^{-1}\left({3 \brace 1}x^{\underline{1}} + {3 \brace 2}x^{\underline{2}} + {3 \brace 3}x^{\underline{3}}\right) = \tfrac{x^{\underline{2}}}{2} + x^{\underline{3}} + \tfrac{x^{\underline{4}}}{4}.$$

Each term $x^{\underline{m}}$ is then expressed in terms of ordinary powers of x

$$\begin{aligned}
x^{\underline{2}} &= {2 \brack 2}x^2 - {2 \brack 1}x^1 = x^2 - x,\\
x^{\underline{3}} &= {3 \brack 3}x^3 - {3 \brack 2}x^2 + {3 \brack 1}x^1 = x^3 - 3x^2 + 2x,\\
x^{\underline{4}} &= {4 \brack 4}x^4 - {4 \brack 3}x^3 + {4 \brack 2}x^2 - {4 \brack 1}x^1 = x^4 - 6x^3 + 11x^2 - 6x,
\end{aligned}$$

so $\Delta^{-1}x^3 = \frac{1}{2}(x^2 - x) + (x^3 - 3x^2 + 2x) + \frac{1}{4}(x^4 - 6x^3 + 11x^2 - 6x) = \frac{1}{4}(x^4 - 2x^3 + x^2)$. Evaluating this antidifference between the limits $x = 1$ and $x = n + 1$ gives $S^3(n) = \frac{1}{4}n^2(n+1)^2$. See §3.5.3, Fact 1.

3.6 ASYMPTOTICS OF SEQUENCES

An exact formula for the terms of a sequence may be unwieldy. For example, it is difficult to estimate the magnitude of the central binomial coefficient $\binom{2n}{n} = \frac{(2n)!}{(n!)^2}$ from the definition of the factorial function alone. On the other hand, Stirling's approximation formula (§3.6.2) leads to the asymptotic estimate $\frac{4^n}{\sqrt{\pi n}}$. In applying asymptotic analysis, various "rules of thumb" help bypass tedious derivations. In practice, these rules almost always lead to correct results that can be proved by more rigorous methods. In the following discussions of asymptotic properties, the parameter tending to infinity is denoted by n. Both the subscripted notation a_n and the functional notation $f(n)$ are used to denote a sequence. The notation $f(n) \sim g(n)$ (f is *asymptotic* to g) means that $f(n) \neq 0$ for sufficiently large n and $\lim_{n\to\infty} \frac{g(n)}{f(n)} = 1$.

3.6.1 APPROXIMATE SOLUTIONS TO RECURRENCES

Although recurrences are a natural source of sequences, they often yield only crude asymptotic information. As a general rule, it helps to derive a summation or a generating function from the recurrence before obtaining asymptotic estimates.

Facts:

1. *Rule of thumb*: Suppose a recurrence for some sequence a_n can be transformed into a recurrence for a related sequence b_n, so that the transformed sequence is approximately homogeneous and linear with constant coefficients (§3.3). Let ρ be the largest positive root of the characteristic equation for the homogeneous constant coefficient recurrence. Then it is probably true that $\frac{b_{n+1}}{b_n} \sim \rho$; i.e., b_n grows roughly like ρ^n.

2. Nonlinear recurrences are *not* covered by Fact 1.

3. Recurrences without fixed degree such as divide-and conquer recurrences (§3.3.5), in which the difference between the largest and smallest subscripts is unbounded, are *not* covered by Fact 1. See [GrKn07] for appropriate techniques.

Examples:

1. Consider the recurrence $D_{n+1} = n(D_n + D_{n-1})$ for $n \geq 1$, and define $d_n = \frac{D_n}{n!}$. Then $d_{n+1} = \frac{n}{n+1} d_n + \frac{1}{n+1} d_{n-1}$, which is quite close to the constant coefficient recurrence $\hat{d}_{n+1} = \hat{d}_n$. Since the characteristic root for this latter approximate recurrence is $\rho = 1$, Fact 1 suggests that $\frac{d_{n+1}}{d_n} \sim 1$, which implies that d_n is close to constant. Thus, we expect the original variable D_n to grow like $n!$. Indeed, if the initial conditions are $D_0 = D_1 = 1$, then $D_n = n!$. With initial conditions $D_0 = 1$, $D_1 = 0$, then D_n is the number of *derangements* of n objects (§2.4.2), in which case D_n is the closest integer to $\frac{n!}{e}$ for $n \geq 1$.

2. The accuracy of Example 1 is unusual. By way of contrast, the number I_n of *involutions* of an n-set (§2.8.1) satisfies the recurrence $I_{n+1} = I_n + nI_{n-1}$ for $n \geq 1$ with $I_0 = I_1 = 1$. By defining $i_n = I_n/(n!)^{1/2}$, then

$$i_{n+1} = \frac{i_n}{(n+1)^{1/2}} + \frac{i_{n-1}}{(1+1/n)^{1/2}},$$

which is nearly the same as the constant coefficient recurrence $\hat{i}_{n+1} = \hat{i}_{n-1}$. The characteristic equation $\rho^2 = 1$ has roots ± 1, so Fact 1 suggests that i_n is nearly constant and hence that I_n grows like $\sqrt{n!}$. The approximation in this case is not so good, because $I_n/\sqrt{n!} \sim e^{\sqrt{n}}/(8\pi e n)^{1/4}$, which is not a constant.

3.6.2 ANALYTIC METHODS FOR DERIVING ASYMPTOTIC ESTIMATES

Concepts and methods from continuous mathematics can be useful in analyzing the asymptotic behavior of sequences. The notion of a generating function (§3.2) will play an important role here.

Definitions:

The ***radius of convergence*** of the series $\sum a_n x^n$ is the number r such that the series converges for all $|x| < r$ and diverges for all $|x| > r$, where $0 \leq r \leq \infty$.

Given a series $A(x) = \sum a_n x^n$, we write $[x^n]A(x) = a_n$.

The ***gamma function*** is the function $\Gamma(x) = \int_0^\infty t^{x-1} e^{-t}\, dt$.

Facts:

1. *Stirling's approximation*: $n! \sim \sqrt{2\pi n}(\frac{n}{e})^n$.

2. $\Gamma(x+1) = x\Gamma(x)$, $\Gamma(n+1) = n!$, and $\Gamma(\frac{1}{2}) = \sqrt{\pi}$.

3. The radius of convergence of $\sum a_n x^n$ is given by $\frac{1}{r} = \limsup_{n\to\infty} |a_n|^{1/n}$.

4. From Fact 3, it follows that $|a_n|$ tends to behave like r^{-n}. Most analytic methods are refinements of this idea: while the absolute value of the radius of convergence gives the exponential growth of the coefficients, the nature of the point where the series ceases to be analytic gives the subexponential growth of the coefficients. See Fact 7.

5. The behavior of $f(z)$ near singularities on its circle of convergence determines the dominant asymptotic behavior of the coefficients of f. Estimates are often based on *Cauchy's integral formula*: $a_n = \oint f(z)z^{-n-1}\,dz$.

6. *Rule of thumb*: Consider the set of values of x for which $f(x) = \sum a_n x^n$ is either infinite or undefined, or involves computing a nonintegral power of 0. The absolute value of the least such x is normally the radius of convergence of $f(x)$. If there is no such x, then $r = \infty$.

7. *Rule of thumb*: As seen in Fact 4, the *modulus* of the radius of convergence of $f(x) = \sum a_n x^n$ determines the exponential growth of a_n. Additionally, the *nature* of the function at the radius of convergence determines the subexponential growth of the coefficients.

8. *Rule of thumb*: A very general example of Fact 7 is the following. Suppose that $0 < r < \infty$ is the radius of convergence of $f(x)$, that $g(x)$ has a larger radius of convergence, and that

$$f(x) - g(x) \sim C\left(-\ln(1-\frac{x}{r})\right)^b \left(1-\frac{x}{r}\right)^c \quad \text{as} \quad x \to r^-$$

for some constants C, b, and c, where it is not the case that both $b = 0$ and c is a nonnegative integer. (Often $g(x) = 0$.) Then it is probably true that

$$[x^n]f(x) \sim \begin{cases} C\binom{n-c-1}{n}(\ln n)^b r^{-n}, & \text{if } c \neq 0, \\ Cb\,\frac{(\ln n)^{b-1}}{n}\,r^{-n}, & \text{if } c = 0. \end{cases}$$

9. *Rule of thumb*: Let $a(x) = \frac{d\ln f(x)}{d\ln x}$ and $b(x) = \frac{da(x)}{d\ln x}$. Suppose that $a(r_n) = n$ has a solution with $0 < r_n < r$ and that $b(r_n) \in o(n^2)$. Then it is probably true that

$$a_n \sim \frac{f(r_n)r_n^{-n}}{\sqrt{2\pi b(r_n)}}.$$

Examples:

1. The number D_n of derangements (§2.4.2) has the exponential generating function $f(x) = \sum D_n \frac{x^n}{n!} = \frac{e^{-x}}{1-x}$. Since evaluation for $x = 1$ involves division by 0, it follows that $r = 1$. Since $\frac{e^{-x}}{1-x} \sim \frac{e^{-1}}{1-x}$ as $x \to 1^-$, take $g(x) = 0$, $C = e^{-1}$, $b = 0$, and $c = -1$. Fact 8 suggests that $D_n \sim \frac{n!}{e}$, which is correct.

2. The number b_n of left-right binary n-leaved trees has the generating function $f(x) = \frac{1}{2}\left(1 - \sqrt{1-4x}\right)$. (See §9.3.3.) In this case $r = \frac{1}{4}$ since $f(\frac{1}{4})$ requires computing a fractional power of 0. Take $g(x) = \frac{1}{2}$, $C = \frac{1}{2}$, $b = 0$, and $c = \frac{1}{2}$ to suspect from Fact 8 that

$$b_n \sim -\frac{1}{2}\binom{n-\frac{3}{2}}{n}4^n = \frac{-\Gamma(n-\frac{1}{2})4^n}{2\Gamma(n+1)\Gamma(-\frac{1}{2})} \sim \frac{4^{n-1}}{\sqrt{\pi n^3}},$$

which is valid. (Facts 1 and 2 have also been used.) This estimate converges rather rapidly—by the time $n = 40$, the estimate is less than 0.1% below b_{40}.

3. Since $\sum \frac{x^n}{n!} = e^x$, $n!$ can be estimated by taking $a(x) = b(x) = x$ and $r_n = n$ in Fact 9. This gives $\dfrac{1}{n!} \sim \dfrac{e^n n^{-n}}{\sqrt{2\pi n}}$, which is Stirling's asymptotic formula.

4. The number B_n of partitions of an n-set (§2.5.2) satisfies $\sum B_n \frac{x^n}{n!} = \exp(e^x - 1)$. In this case, $r = \infty$. Since $a(x) = xe^x$ and $b(x) = x(x+1)e^x$, it follows that r_n is the solution to $r_n \exp(r_n) = n$ and that $b(r_n) = (r_n + 1)n \sim nr_n \in o(n^2)$. Fact 9 suggests

$$B_n \sim \frac{n!\exp(e^{r_n} - 1)}{r_n^n\sqrt{2\pi n r_n}} = \frac{n!\exp(n/r_n - 1)}{r_n^n\sqrt{2\pi n r_n}}.$$

This estimate is correct, though the estimate converges quite slowly, as shown in the following table.

n	10	20	100	200
estimate	1.49×10^5	6.33×10^{13}	5.44×10^{115}	7.01×10^{275}
B_n	1.16×10^5	5.17×10^{13}	4.76×10^{115}	6.25×10^{275}
ratio	1.29	1.22	1.14	1.12

Improved asymptotic estimates exist.

5. Analytic methods can sometimes be used to obtain asymptotic results when only a functional equation is available (see also §3.6.3.) For example, if a_n is the number of n-leaved rooted trees in which each non-leaf node has exactly two children (with left and right not distinguished), the generating function for a_n satisfies $f(x) = x + \big(f(x)^2 + f(x^2)\big)/2$, from which it can be deduced that $a_n \sim Cn^{-3/2}r^{-n}$, where $r = 0.4026975\ldots$ and $C = 0.31877\ldots$ can easily be computed to any desired degree of accuracy. See [BeWi06] for more information.

3.6.3 GENERATING FUNCTION SCHEMES

Specific general expressions defining a given generating function can be applied to automatically give asymptotic results for their coefficients.

Facts:

1. *Rule of thumb*: Assume that the generating function $A(x) = \sum a_n x^n$ satisfies the equation $A(x) = x\phi(A(x))$, where $\phi(t)$ is a nonlinear function, analytic at 0 with $\phi(0) \neq 0$ and $[t^n]\phi(t) \geq 0$ for all values of $n > 0$. This is the so-called *Lagrange scheme*. Then, by means of the *Lagrange inversion formula*, we have

$$a_n = \frac{1}{n}[t^{n-1}]\phi(t)^n.$$

Sometimes this exact formula is useless, and one can exploit analytic methods to provide asymptotic estimates for a_n. More precisely, if R is the radius of convergence of $\phi(t)$ and there exists a solution τ to the equation $\phi(\tau) = \tau\phi'(\tau)$ with $0 < \tau < R$, then

$$a_n \sim \sqrt{\frac{\phi(\tau)}{\phi''(\tau)}}\frac{1}{\sqrt{2\pi n^3}}\left(\frac{\phi(\tau)}{\tau}\right)^n.$$

2. *Rule of thumb*: Systems of functional equations have the same asymptotic form as in Fact 1. Let $A_1(x), \ldots, A_k(x)$ satisfy a functional system of equations of the form $A_1(x) = F_1(x, A_1(x), \ldots, A_k(x))$, $\ldots$, $A_k(x) = F_k(x, A_1(x), \ldots, A_k(x))$, where the functions F_i are nonlinear. Additionally, the system is *irreducible*, namely one cannot simplify it by eliminating equations. Then, under certain technical but general conditions for the functions F_i it is probably true that, for some constants C_i, the exponential growth of the coefficients is of the form

$$[x^n]A_i(x) \sim C_i\frac{1}{\sqrt{n^3}}\rho^{-n}.$$

The constant ρ can be computed analytically as a solution of a system of equations. See [Dr97] for details.

Examples:

1. The Catalan numbers C_n (see §3.1.3) are encoded by the generating function $C(x)$, which satisfies the functional equation $C(x) = 1 + xC(x)^2$. Writing $C(x) - 1 = U(x)$ we obtain $U(x) = x(1 + U(x))^2$. Then $\phi(t) = (1 + t)^2$, and Fact 1 applies directly. This yields $\tau = 1$ and $\phi(\tau)/\tau = 4$. Hence, by Fact 1

$$[x^n]U(x) = [x^n]C(x) = \frac{1}{n+1}\binom{2n}{n} \sim \frac{1}{\sqrt{\pi n^3}}4^n.$$

Compare this result with Example 2 of §3.6.2. Observe that the asymptotic estimate can be obtained either by applying Stirling's formula to the Catalan number (expressed using a binomial coefficient), or directly by using Fact 1.

2. Consider the family of rooted trees where each internal vertex has outdegree equal to 2, 3 or 4. Then the generating function $T(x)$ associated with this family satisfies the equation $T(x) = x(1+T(x)^2+T(x)^3+T(x)^4)$, where x encodes vertices (see [FlSe09]). In this case, $\phi(t) = (1+t^2+t^3+t^4)$ and the positive solution to the equation $\phi(\tau) = \tau\phi'(\tau)$ is given by $\tau = 0.56773\ldots$. Finally, the growth constant is $\phi(\tau)/\tau = 2.83443\ldots$.

3.6.4 ASYMPTOTIC ESTIMATES OF MULTIPLY-INDEXED SEQUENCES

Asymptotic estimates for multiply-indexed sequences are considerably more difficult to obtain. To begin with, the meaning of a formula such as

$$\binom{n}{k} \sim \frac{2^n}{\sqrt{\pi n/2}} \exp\left(-\frac{(n-2k)^2}{2n}\right)$$

must be carefully stated, because both n and k are tending to ∞, and the formula is valid only when this happens in such a way that $|2k - n| \in o(n^{3/4})$.

Facts:

1. Most estimates of multiple summations are based on summing over one index at a time.

2. Some analytic results are available in the research literature [Od95]. In particular, Drmota [Dr97] shows that Fact 2 in §3.6.3 can be extended in some situations in order to deal with multiply-indexed sequences.

3. Very recently, some tools arising from multidimensional complex analysis have been exploited to study such questions [PeWi13].

Example:

1. Consider the number of rooted plane trees, expressed in terms of the number of vertices n. This sequence is given by the Catalan numbers. We consider also the number of leaves r. Denote by $t_{n,r}$ the number of rooted plane trees with n vertices and r leaves, and write $T(x,u) = \sum t_{n,r}x^n u^r$. Then it can be shown that $T(x,u)$ satisfies the functional equation

$$T(x,u) = xu + \frac{xT(x,u)}{1 - T(x,u)}.$$

Application of the Lagrange inversion formula (see Fact 1 in §3.6.3) gives

$$t_{n,r} = \frac{1}{n-1}\binom{n-1}{n-r}\binom{n-1}{r}.$$

Using Stirling's approximation formula we get

$$t_{n,r} \sim \frac{1}{\pi n^2} 2^{2n-1} \exp\left(-\frac{(n-2k)^2}{n}\right).$$

Such an estimate can be obtained as well by means of the tools of [Dr97] using complex analytic techniques.

3.7 MECHANICAL SUMMATION PROCEDURES

This section describes mechanical procedures that have been developed to evaluate sums of terms involving binomial coefficients and related factors. These procedures can not only be used to find explicit formulas for many sums, but can also be used to show that no simple closed formulas exist for certain sums. The invention of these mechanical procedures has been a surprising development in combinatorics. The material presented here is mostly adapted from [PeWiZe96], a comprehensive source for material on this topic.

3.7.1 HYPERGEOMETRIC SERIES

Definitions:

A ***geometric series*** is a series of the form $\sum_{k=0}^{\infty} a_k$ where the ratio between two consecutive terms is a constant, i.e., where the ratio $\frac{a_{k+1}}{a_k}$ is a constant for all $k = 0, 1, 2, \ldots$.

A ***hypergeometric series*** is a series of the form $\sum_{k=0}^{\infty} t_k$ where $t_0 = 1$ and the ratio of two consecutive terms is a rational function of the summation index k, i.e., the ratio $\frac{t_{k+1}}{t_k} = \frac{P(k)}{Q(k)}$ where $P(k)$ and $Q(k)$ are polynomials in the integer k. The terms of a hypergeometric series are called ***hypergeometric terms***.

When the numerator $P(k)$ and denominator $Q(k)$ of this ratio are completely factored to give

$$\frac{P(k)}{Q(k)} = \frac{(k+a_1)(k+a_2)\ldots(k+a_p)}{(k+b_1)(k+b_2)\ldots(k+b_q)(k+1)},$$

where x is a constant, this hypergeometric series is denoted by

$${}_pF_q = \begin{bmatrix} a_1 & a_2 & \ldots & a_p \\ b_1 & b_2 & \ldots & b_q \end{bmatrix}; x \Bigg].$$

Note: If there is no factor $k+1$ in the denominator $Q(k)$ when it is factored, by convention the factor $k+1$ is added to both the numerator $P(k)$ and denominator $Q(k)$. Also, a horizontal dash is used to indicate the absence of factors in the numerator or in the denominator.

The hypergeometric terms s_n and t_n are ***similar***, denoted $s_n \sim t_n$, if their ratio s_n/t_n is a rational function of n. Otherwise, these terms are called ***dissimilar***.

Facts:

1. A geometric series is also a hypergeometric series.

2. If s_n is a hypergeometric term, then $\frac{1}{s_n}$ is also a hypergeometric term. (Equivalently, if $\sum_{k=0}^{\infty} s_n$ is a hypergeometric series, then $\sum_{k=0}^{\infty} \frac{1}{s_n}$ also is.)

3. In common usage, instead of stating that the series $\sum_{k=0}^{\infty} s_n$ is a hypergeometric series, it is stated that s_n is a hypergeometric term. This means exactly the same thing.

4. If s_n and t_n are hypergeometric terms, then $s_n t_n$ is a hypergeometric term. (Equivalently, if $\sum_{k=0}^{\infty} s_n$ and $\sum_{k=0}^{\infty} t_n$ are hypergeometric series, then $\sum_{k=0}^{\infty} s_n t_n$ is a hypergeometric series.)

5. If s_n is a hypergeometric term and s_n is not a constant, then $s_{n+1} - s_n$ is a hypergeometric term similar to s_n.

6. If s_n and t_n are hypergeometric terms and $s_n + t_n \neq 0$ for all n, then $s_n + t_n$ is hypergeometric if and only if s_n and t_n are similar.

7. If $t_n^{(1)}, t_n^{(2)}, \ldots, t_n^{(k)}$ are hypergeometric terms with $\sum_{i=1}^{k} t_n^{(i)} = 0$, then $t_n^{(i)} \sim t_n^{(j)}$ for some i and j with $1 \leq i < j \leq k$.

8. A sum of a fixed number of hypergeometric terms can be expressed as a sum of pairwise dissimilar hypergeometric terms.

9. The terms of a hypergeometric series can be expressed using rising powers $a^{\overline{n}}$ (also known as rising factorials and denoted by $(a)_n$) (see §3.4.2) as follows:

$$
{}_pF_q = \begin{bmatrix} a_1 & a_2 & \ldots & a_p \\ b_1 & b_2 & \ldots & b_q \end{bmatrix}; x\Big] = \sum_{k=0}^{\infty} \frac{(a_1)^{\overline{k}}(a_2)^{\overline{k}} \ldots (a_p)^{\overline{k}}}{(b_1)^{\overline{k}}(b_2)^{\overline{k}} \ldots (b_q)^{\overline{k}}} \frac{x^k}{k!}.
$$

10. There are a large number of well-known hypergeometric identities (see Facts 12–17, for example) that can be used as a starting point when a closed form for a sum of hypergeometric terms is sought.

11. There are many rules that transform a hypergeometric series with one parameter set into a different hypergeometric series with a second parameter set. Such transformation rules can be helpful in constructing closed forms for sums of hypergeometric terms.

12. ${}_1F_1\left[\begin{matrix}1\\1\end{matrix}; x\right] = e^x.$

13. ${}_1F_0\left[\begin{matrix}a\\-\end{matrix}; x\right] = \dfrac{1}{(1-x)^a}.$

14. *Gauss's ${}_2F_1$ identity*: If b is zero or a negative integer or the real part of $c - a - b$ is positive, then

$$
{}_2F_1\left[\begin{matrix}a & b\\ c & \end{matrix}; 1\right] = \frac{\Gamma(c-a-b)\Gamma(c)}{\Gamma(c-a)\Gamma(c-b)}
$$

where Γ is the gamma function (so $\Gamma(n) = (n-1)!$ when n is a positive integer).

15. *Kummer's ${}_2F_1$ identity*: If $a - b + c = 1$, then

$$
{}_2F_1\left[\begin{matrix}a & b\\ c & \end{matrix}; -1\right] = \frac{\Gamma(\frac{b}{2}+1)\Gamma(b-a+1)}{\Gamma(b+1)\Gamma(\frac{b}{2}-a+1)}
$$

and when b is a negative integer, this can be expressed as

$$
{}_2F_1\left[\begin{matrix}a & b\\ c & \end{matrix}; -1\right] = 2\cos(\tfrac{\pi b}{2})\frac{\Gamma(|b|)\Gamma(b-a+1)}{\Gamma(\frac{|b|}{2})\Gamma(\frac{b}{2}-a+1)}.
$$

16. *Saalschütz's ${}_3F_2$ identity*: If $d+e=a+b+c+1$ and c is a negative integer, then

$$ {}_3F_2\left[\begin{matrix} a & b & c \\ d & e & \end{matrix};1\right] = \frac{(d-a)^{\overline{|c|}}(d-b)^{\overline{|c|}}}{d^{\overline{|c|}}(d-a-b)^{\overline{|c|}}}. $$

17. *Dixon's identity*: If $1+\frac{a}{2}-b-c>0$, $d=a-b+1$, and $e=a-c+1$, then

$$ {}_3F_2\left[\begin{matrix} a & b & c \\ d & e & \end{matrix};1\right] = \frac{(\frac{a}{2})!(a-b)!(a-c)!(\frac{a}{2}-b-c)!}{a!(\frac{a}{2}-b)!(\frac{a}{2}-c)!(a-b-c)!}. $$

The more familiar form of this identity reads

$$ \sum_k (-1)^k \binom{a+b}{a+k}\binom{a+c}{c+k}\binom{b+c}{b+k} = \frac{(a+b+c)!}{a!b!c!}. $$

18. *Clausen's ${}_4F_3$ identity*: If d is a negative integer or zero and $a+b+c-d=\frac{1}{2}$, $e=a+b+\frac{1}{2}$, and $a+f=d+1=b+g$, then

$$ {}_4F_3\left[\begin{matrix} a & b & c & d \\ e & f & g & \end{matrix};1\right] = \frac{(2a)^{\overline{|d|}}(a+b)^{\overline{|d|}}(2b)^{\overline{|d|}}}{(2a+2b)^{\overline{|d|}}(a)^{\overline{|d|}}(b)^{\overline{|d|}}}. $$

Examples:

1. The series $\sum_{k=0}^{\infty} 3\cdot(-5)^k$ is a geometric series. The series $\sum_{k=0}^{\infty} n2^n$ is not a geometric series.

2. The series $\sum_{k=0}^{\infty} t_k$ is a hypergeometric series when t_k equals 2^k, $(k+1)^2$, $\frac{1}{2k+3}$, or $\frac{1}{(2k+1)(k+3)!}$, but is not hypergeometric when $t_k = 2^k+1$.

3. The series $\sum_{k=0}^{\infty} \frac{3^k}{k!^4}$ equals ${}_0F_3\left[\begin{matrix} - \\ 1\ 1\ 1 \end{matrix};3\right]$ since the ratio of the $(k{+}1)$st and kth terms is $\frac{3}{(k+1)^4}$.

4. A closed form for $S_n = \sum_{k=0}^{\infty}(-1)^k\binom{2n}{k}^2$ can be found by first noting that $S_n = {}_2F_1\left[\begin{matrix} -2n & -2n \\ 1 & \end{matrix};-1\right]$ since the ratio between successive terms of the sum is $\frac{-(k-2n)^2}{(k+1)^2}$. This shows that Kummer's ${}_2F_1$ identity can be invoked with $a=-2n$, $b=-2n$, and $c=1$, producing the equality $S_n = \frac{2(-1)^n(2n-1)!}{n!(n-1)!} = (-1)^n\binom{2n}{n}$.

5. An example of a transformation rule for hypergeometric functions is provided by

$$ {}_2F_1\left[\begin{matrix} a & b \\ c & \end{matrix};x\right] = (1-x)^{c-a-b}{}_2F_1\left[\begin{matrix} c-a & c-b \\ c & \end{matrix};x\right]. $$

3.7.2 ALGORITHMS TO PRODUCE CLOSED FORMS FOR SUMS OF HYPERGEOMETRIC TERMS

Definitions:

A function $F(n,k)$ is called ***doubly hypergeometric*** if both $\frac{F(n+1,k)}{F(n,k)}$ and $\frac{F(n,k+1)}{F(n,k)}$ are rational functions of n and k.

A function $F(n,k)$ is a ***proper hypergeometric term*** if it can be expressed as

$$F(n,k) = P(n,k)\frac{\prod_{i=1}^{G}(a_in+b_ik+c_i)!}{\prod_{i=1}^{H}(u_in+v_ik+w_i)!}\,x^k$$

where x is a variable, $P(n,k)$ is a polynomial in n and k, G and H are nonnegative integers, and all the coefficients a_i, b_i, u_i, and v_i are integers.

A function $F(n,k)$ of the form

$$F(n,k) = P(n,k)\frac{\prod\limits_{i=1}^{G}(a_in+b_ik+c_i)!}{\prod\limits_{i=1}^{H}(u_in+v_ik+w_i)!}\,x^k$$

is said to be ***well-defined*** at (n,k) if none of the terms $(a_in+b_ik+c_i)$ in the product is a negative integer. The function $F(n,k)$ is defined to have the value 0 if F is well-defined at (n,k) and there is a term $(u_in+v_ik+w_i)$ in the product that is a negative integer or $P(n,k)=0$.

Facts:

1. If $F(n,k)$ is a proper hypergeometric term, then there exist positive integers L and M and polynomials $a_{i,j}(n)$ for $i=0,1,\ldots,L$ and $j=0,1,\ldots,M$, not all zero, such that

$$\sum_{i=0}^{L}\sum_{j=0}^{M} a_{i,j}(n)F(n-j,k-i)=0$$

for all pairs (n,k) with $F(n,k)\neq 0$ and all the values of $F(n,k)$ in this double sum are well-defined. Moreover, there is such a recurrence with M equal to $M'=\sum_s |b_s|+\sum_t |v_t|$ and L equal to $L'=\deg(P)+1+M'(-1+\sum_s |a_s|+\sum_t |u_t|)$, where the a_i, b_i, u_i, v_i and P come from an expression of $F(n,k)$ as a hypergeometric term as specified in the definition.

2. *Sister Celine's algorithm*: This algorithm, developed in 1945 by Sister Mary Celine Fasenmyer (1906–1996), can be used to find recurrence relations for sums of the form $f(n)=\sum_k F(n,k)$ where F is a doubly hypergeometric function. The algorithm finds a recurrence of the form $\sum_{i=0}^{L}\sum_{j=0}^{M} a_{i,j}(n)F(n-j,k-i)=0$ by proceeding as follows:

- Start with trial values of L and M, such as $L=1$, $M=1$.
- Assume that a recurrence relation of the type sought exists with these values of L and M, with the coefficients $a_{i,j}(n)$ to be determined, if possible.
- Divide each term in the sum of the recurrence by $F(n,k)$, then reduce each fraction $F(n-j,k-i)/F(n,k)$, simplifying the ratios of factorials so only rational functions of n and k are left.
- Combine the terms in the sum using a common denominator, collecting the numerator into a single polynomial in k.
- Solve the system of linear equations for the $a_{i,j}(n)$ that results when the coefficients of each power of k in the numerator polynomial are equated to zero.
- If these steps fail, repeat the procedure with larger values of L and M; by Fact 2, this procedure is guaranteed to eventually work.

3. *Gosper's algorithm*: This algorithm, developed by R. W. Gosper, Jr., can be used to determine, given a hypergeometric term t_n, whether there is a hypergeometric term z_n such that $z_{n+1} - z_n = t_n$. When there is such a hypergeometric term z_n, the algorithm also produces such a term.

4. Gosper's algorithm takes a hypergeometric term t_n as input and performs the following general steps (for details see [PeWiZe96]):

- Let $r(n) = t_{n+1}/t_n$; this is a rational function of n since t is hypergeometric.
- Find polynomials $a(n)$, $b(n)$, and $c(n)$ such that $\gcd(a(n), b(n+h)) = 1$ whenever h is a nonnegative integer; this is done using the following steps:
  - ◇ Let $r(n) = K \cdot \frac{f(n)}{g(n)}$ where $f(n)$ and $g(n)$ are monic relatively prime polynomials and K is a constant, let $R(h)$ be the resultant of $f(n)$ and $g(n+h)$ (which is the product of the zeros of $g(n+h)$ at the zeros of $f(n)$), and let $S = \{h_1, h_2, \ldots, h_N\}$ be the set of nonnegative integer zeros of $R(h)$ where $0 \leq h_1 < h_2 < \cdots < h_N$.
  - ◇ Let $p_0(n) = f(n)$ and $q_0(n) = g(n)$; then for $j = 1, 2, \ldots, N$ carry out the following steps:
    $s_j(n) := \gcd(p_{j-1}(n), q_{j-1}(n + h_j))$;
    $p_j(n) := p_{j-1}(n)/s_j(n)$;
    $q_j(n) := q_{j-1}(n)/s_j(n - h_j)$.
- Take $a(n) := Kp_N(n)$; $b(n) := q_N(n)$; $c(n) := \prod_{i=1}^{N} \prod_{j=1}^{h_i} s_i(n-j)$.
- Find a nonzero polynomial $x(n)$ such that $a(n)x(n+1) - b(n-1)x(n) = c(n)$ if one exists; such a polynomial can be found using the method of undetermined coefficients to find a nonzero polynomial of degree d or less, where the degree d depends on the polynomials $a(n)$, $b(n)$, and $c(n)$. If no such polynomial exists, then the algorithm fails. The degree d is determined by the following rules:
  - ◇ When $\deg a(n) \neq \deg b(n)$ or $\deg a(n) = \deg b(n)$ but the leading coefficients of $a(n)$ and $b(n)$ differ, then $d = \deg c(n) - \max(\deg a(n), \deg b(n))$.
  - ◇ When $\deg a(n) = \deg b(n)$ and the leading coefficients of $a(n)$ and $b(n)$ agree, $d = \max(\deg c(n) - \deg a(n) + 1, (B-A)/L)$ where $a(n) = Ln^k + An^{k-1} + \cdots$ and $b(n-1) = Ln^k + Bn^{k-1} + \cdots$; if this d is negative, then no such polynomial $x(n)$ exists.
- Let $z_n = t_n \cdot b(n-1)x(n)/c(n)$; it follows that $z_{n+1} - z_n = t_n$.

5. When Gosper's algorithm fails, this shows that a sum of hypergeometric terms cannot be expressed as a hypergeometric term plus a constant.

6. Programs in both *Maple* and *Mathematica* implementing algorithms described in this section can be found at the following sites:

- `http://www.math.upenn.edu/~wilf/AeqB.html`
- `http://www.math.rutgers.edu/~zeilberg/programs.html`

Examples:

1. The function $F(n,k) = \frac{1}{5n+2k+2}$ is a proper hypergeometric term since $F(n,k)$ can be expressed as $F(n,k) = \frac{(5n+2k+1)!}{(5n+2k+2)!}$.

2. The function $F(n,k) = \frac{1}{n^2+k^3+5}$ is not a proper hypergeometric term.

3. Sister Celine's algorithm can be used to find a recurrence relation satisfied by the function $f(n) = \sum_k F(n,k)$ where $F(n,k) = k\binom{n}{k}$ for $n = 0, 1, 2, \ldots$. The algorithm proceeds by finding a recurrence relation of the form $a(n)F(n,k) + b(n)F(n+1,k) +$

$c(n)F(n,k+1)+d(n)F(n+1,k+1)=0$. Since $F(n,k)=k\binom{n}{k}$, this recurrence relation simplifies to $a(n)+b(n)\cdot\frac{n+1}{n+1-k}+c(n)\cdot\frac{n-k}{k}+d(n)\cdot\frac{n+1}{k}=0$. Putting the left-hand side of this equation over a common denominator and expressing it as a polynomial in k, four equations in the unknowns $a(n)$, $b(n)$, $c(n)$, and $d(n)$ are produced. These equations have the following solutions: $a(n)=t(-1-\frac{1}{n})$, $b(n)=0$, $c(n)=t(-1-\frac{1}{n})$, $d=t$, where t is a constant. This produces the recurrence relation $(-1-\frac{1}{n})F(n,k)+(-1-\frac{1}{n})F(n,k+1)+F(n+1,k+1)=0$, which can be summed over all integers k and simplified to produce the recurrence relation $f(n+1)=2\cdot\frac{n+1}{n}f(n)$, with $f(1)=1$. From this it follows that $f(n)=n2^{n-1}$.

4. As shown in [PeWiZe96], Sister Celine's algorithm can be used to find an identity for $f(n)=\sum_k F(n,k)$ where $F(n,k)=\binom{n}{k}\binom{2n}{k}(-2)^{n-k}$. A recurrence for $F(n,k)$ can be found using her techniques (which can be carried out using either *Maple* or *Mathematica* software, for example). An identity that can be found this way is: $-8(n-1)F(n-2,k-1)-2(2n-1)F(n-1,k-1)+4(n-1)F(n-2,k)+2(2n-1)F(n-1,k)+nF(n,k)=0$. When this is summed over all integers k, the recurrence relation $nf(n)-4(n-1)f(n-2)=0$ is obtained. From the definition of f it follows that $f(0)=1$ and $f(1)=0$. From the initial conditions and the recurrence relation for $f(n)$, it follows that $f(n)=0$ when n is odd and $f(n)=\binom{n}{n/2}$ when n is even. (This is known as the *Reed-Dawson identity*.)

5. Gosper's algorithm can be used to find a closed form for $S_n=\sum_{k=1}^{n} k\,k!$. Let $t_n=n\,n!$. Following Gosper's algorithm gives $r(n)=\frac{t_{n+1}}{t_n}=\frac{(n+1)^2}{n}$, $a(n)=n+1$, $b(n)=1$, and $c(n)=n$. The polynomial $x(n)$ must satisfy $(n+1)x(n+1)-x(n)=n$; the polynomial $x(n)=1$ is such a solution. It follows that $z_n=n!$ satisfies $z_{n+1}-z_n=t_n$. Hence $s_n=z_n-z_1=n!-1$ and $S_n=s_{n+1}=(n+1)!-1$.

6. Gosper's algorithm can be used to show that $S_n=\sum_{k=0}^{n} k!$ cannot be expressed as a hypergeometric term plus a constant. Let $t_n=n!$. Following Gosper's algorithm gives $r(n)=\frac{t_{n+1}}{t_n}=n+1$, $a(n)=n+1$, $b(n)=1$, $c(n)=1$. The polynomial $x(n)$ must satisfy $(n+1)x(n+1)-x(n)=1$ and must have a degree less than zero. It follows that there is no closed form for $\sum_{k=0}^{n} k!$ of the type specified.

3.7.3 CERTIFYING THE TRUTH OF COMBINATORIAL IDENTITIES

Definitions:

A pair of functions (F,G) is called a ***WZ pair*** (after Wilf and Zeilberger) if $F(n+1,k)-F(n,k)=G(n,k+1)-G(n,k)$. If (F,G) is a WZ pair, then F is called the ***WZ mate*** of G and vice versa.

A ***WZ certificate*** $R(n,k)$ is a function that can be used to verify the hypergeometric identity $\sum_k f(n,k)=r(n)$ by creating a WZ pair (F,G) with $F(n,k)=\frac{f(n,k)}{r(n)}$ when $r(n)\neq 0$ and $F(n,k)=f(n,k)$ when $r(n)=0$ and $G(n,k)=R(n,k)F(n,k)$. When a hypergeometric identity is proved using a a WZ certificate, this proof is called a ***WZ proof***.

Facts:

1. If (F,G) is a WZ pair such that for each integer $n\geq 0$, $\lim_{k\to\pm\infty} G(n,k)=0$, then $\sum_k F(n,k)$ is a constant for $n=0,1,2,\ldots$.

2. If (F,G) is a WZ pair such that for each integer k, the limit $f_k=\lim_{n\to\infty} F(n,k)$ exists and is finite, for every nonnegative integer n it is the case that $\lim_{k\to\pm\infty} G(n,k)=0$, and $\lim_{L\to\infty}\sum_{n\geq 0} G(n,-L)=0$, then $\sum_{n\geq 0} G(n,k)=\sum_{j\leq k-1}(f_j-F(0,j))$.

3. An identity $\sum_k f(n,k) = r(n)$ can be verified using its WZ certificate $R(n,k)$ as follows:

- If $r(n) \neq 0$, define $F(n,k)$ by $F(n,k) = \frac{f(n,k)}{r(n)}$, else define $F(n,k) = f(n,k)$; define $G(n,k)$ by $G(n,k) = R(n,k)F(n,k)$.
- Confirm that (F,G) is a WZ pair, i.e., that $F(n+1,k) - F(n,k) = G(n,k+1) - G(n,k)$, by dividing the factorials out and verifying the polynomial identity that results.
- Verify that the original identity holds for a particular value of n.

4. The WZ certificate of an identity $\sum_k f(n,k) = r(n)$ can be found using the following steps:

- If $r(n) \neq 0$, define $F(n,k)$ to be $F(n,k) = \frac{f(n,k)}{r(n)}$, else define $F(n,k)$ to be $F(n,k) = f(n,k)$.
- Let $f(k) = F(n+1,k) - F(n,k)$; provide $f(k)$ as input to Gosper's algorithm.
- If Gosper's algorithm produces $G(n,k)$ as output, it is the WZ mate of F and the function $R(n,k) = \frac{G(n,k)}{F(n,k)}$ is the WZ certificate of the identity $\sum_k F(n,k) = C$ where C is a constant.

If Gosper's algorithm fails, this algorithm also fails.

Examples:

1. To prove the identity $f(n) = \sum_k \binom{n}{k}^2 = \binom{2n}{n}$, express it in the form $\sum_k F(n,k) = 1$ where $F(n,k) = \binom{n}{k}^2 / \binom{2n}{n}$. The identity can be proved by taking the function $R(n,k) = \frac{k^2(3n-2k+3)}{2(2n+1)(n-k+1)^2}$ as its WZ certificate. (This certificate can be obtained using Gosper's algorithm.)

2. To prove Gauss's ${}_2F_1$ identity via a WZ proof, express it in the form $\sum_k F(n,k) = 1$ where $F(n,k) = \frac{(n+k)!(b+k)!(c-n-1)!(c-b-1)!}{(c+k)!(n-1)!(c-n-b-1)!(k+1)!(b-1)!}$. The identity can then be proved by taking the function $R(n,k) = \frac{(k+1)(k+c)}{n(n+1-c)}$ as its WZ certificate. (This certificate can be obtained using Gosper's algorithm.)

NUMBER THEORY

INTRODUCTION

This chapter covers the basics of number theory. Number theory, a subject with a long and rich history, has become increasingly important because of its applications to computer science and cryptography. The core topics of number theory, such as divisibility, radix representations, greatest common divisors, primes, factorization, congruences, diophantine equations, and continued fractions, are covered here. Algorithms for finding greatest common divisors, large primes, and factorizations of integers are described.

There are many famous problems in number theory, including some that have been solved only recently, such as Fermat's last theorem, and others that have eluded resolution, such as the Goldbach conjecture. The status of such problems is described in this chapter. New discoveries in number theory, such as new large primes, are being made at an increasingly fast pace. This chapter describes the current state of knowledge and provides pointers to Internet sources where the latest facts can be found.

GLOSSARY

algebraic integer: a root of a monic polynomial with integer coefficients.

algebraic number: a root of a polynomial with integer coefficients.

arithmetic function: a function defined for all positive integers.

Bachet's equation: a diophantine equation of the form $y^2 = x^3 + k$, where k is a given integer.

base: the positive integer b, with $b > 1$, in the expansion $n = a_k b^k + a_{k-1} b^{k-1} + \cdots + a_1 b + a_0$, where $0 \le a_i \le b - 1$ for $i = 0, 1, 2, \ldots, k$.

binary coded decimal expansion: the expansion produced by replacing each decimal digit of an integer by the four-bit binary expansion of that digit.

binary representation of an integer: the base two expansion of this integer.

Carmichael number: a positive integer that is a pseudoprime to all bases.

Catalan's equation: the diophantine equation $x^m - y^n = 1$, where solutions in integers greater than 1 are sought for x, y, m, and n.

Chinese remainder theorem: the theorem that states that given a set of congruences $x \equiv a_i \pmod{m_i}$ for $i = 1, 2, \ldots, n$, where the integers m_i, $i = 1, 2, \ldots, n$, are pairwise relatively prime, there is a unique simultaneous solution of these congruences modulo $M = m_1 m_2 \ldots m_n$.

complete system of residues modulo m: a set of integers such that every integer is congruent modulo m to exactly one integer in the set.

composite: a positive integer that has a factor other than 1 and itself.

congruence class of a modulo m: the set of integers congruent to a modulo m.

congruent integers modulo m: two integers with a difference divisible by m.

continued fraction: a finite or infinite expression of the form $a_0 + 1/(a_1 + 1/(a_2 + \cdots$; usually abbreviated $[a_0, a_1, a_2, \ldots]$.

convergent: a rational fraction obtained by truncating a continued fraction.

coprime (integers): integers that have no positive common divisor other than 1; see *relatively prime*.

cyclotomic field: a field obtained by adjoining a primitive root of unity to the field of rational numbers.

diophantine approximation: the approximation of a number by numbers belonging to a specified set, often the set of rational numbers.

diophantine equation: an equation together with the restriction that the only solutions of the equation of interest are those belonging to a specified set, often the set of integers or the set of rational numbers.

Dirichlet's theorem (on primes in arithmetic progressions): the theorem that states that there are infinitely many primes in each arithmetic progression of the form $an + b$, where a and b are relatively prime positive integers.

discrete logarithm of a to the base r modulo m: the integer x such that $r^x \equiv a \pmod{m}$, where r is a primitive root of m and $\gcd(a, m) = 1$.

divides: the integer a divides the integer b, written $a \mid b$, if there is an integer c such that $b = ac$.

divisor: (1) an integer d such that d divides a for a given integer a, or (2) the positive integer d that is divided into the integer a to yield $a = dq + r$ with $0 \le r < d$.

elliptic curve: for prime $p > 3$, the set of solutions (x, y) to the congruence $y^2 \equiv x^3 + ax + b \pmod{p}$, where $4a^3 + 27b^2 \not\equiv 0 \pmod{p}$, together with a special point $\mathcal{O}$, called the *point at infinity*.

elliptic curve method (***ECM***): a factoring technique invented by Lenstra that is based on the theory of elliptic curves.

Euler phi-function: the function $\phi(n)$ whose value at the positive integer n is the number of positive integers not exceeding n relatively prime to n.

Euler's theorem: the theorem that states that if n is a positive integer and a is an integer with $\gcd(a, n) = 1$, then $a^{\phi(n)} \equiv 1 \pmod{n}$, where $\phi(n)$ is the value of the Euler phi-function at n.

exactly divides: if p is a prime and n is a positive integer, p^r exactly divides n, written $p^r || n$, if p^r divides n, but p^{r+1} does not divide n.

factor (of an integer n): an integer that divides n.

factorization algorithm: an algorithm whose input is a positive integer and whose output is the prime factorization of this integer.

Farey series (of order n): the set of fractions $\frac{h}{k}$, where h and k are relatively prime nonnegative integers with $0 \leq h \leq k \leq n$ and $k \neq 0$.

Fermat equation: the diophantine equation $x^n + y^n = z^n$, where n is an integer greater than 2 and x, y, z are nonzero integers.

Fermat number: a number of the form $2^{2^n} + 1$, where n is a nonnegative integer.

Fermat prime: a prime Fermat number.

Fermat's last theorem: the theorem that states that if n is a positive integer greater than 2, then the equation $x^n + y^n = z^n$ has no solutions in integers with $xyz \neq 0$.

Fermat's little theorem: the theorem that states that if p is prime and a is an integer, then $a^p \equiv a \pmod{p}$.

Fibonacci numbers: the sequence of numbers defined by $F_0 = 0$, $F_1 = 1$, and $F_n = F_{n-1} + F_{n-2}$ for $n = 2, 3, 4, \ldots$.

fundamental theorem of arithmetic: the theorem that states that every positive integer has a unique representation as the product of primes written in nondecreasing order.

Gaussian integers: the set of numbers of the form $a + bi$, where a and b are integers and i is $\sqrt{-1}$.

greatest common divisor gcd (of a set of integers): the largest integer that divides all integers in the set; the greatest common divisor of the integers $a_1, a_2, \ldots, a_n$ is denoted $\gcd(a_1, a_2, \ldots, a_n)$.

hexadecimal representation (of an integer): the base sixteen representation of this integer.

index of a to the base r modulo m: the smallest nonnegative integer x, denoted $\operatorname{ind}_r a$, such that $r^x \equiv a \pmod{m}$, where r is a primitive root of m and $\gcd(a, m) = 1$.

integer of an algebraic number field: an algebraic integer that belongs to this field.

inverse of an integer a modulo m: an integer $\overline{a}$ such that $a\overline{a} \equiv 1 \pmod{m}$; here $\gcd(a, m) = 1$.

irrational number: a real number that is not the ratio of two integers.

Jacobi symbol: a generalization of the Legendre symbol.

Kronecker symbol: a generalization of the Legendre and Jacobi symbols.

least common multiple (of a set of integers): the smallest positive integer that is divisible by all integers in the set.

least nonnegative residue of a modulo m: the remainder when a is divided by m; it is the smallest nonnegative integer congruent to a modulo m, written $a \mathbin{\mathbf{mod}} m$.

Legendre symbol: the symbol $\left(\frac{a}{p}\right)$ that has the value 1 if a is a square modulo p and -1 if a is not a square modulo p; here p is a prime and a is an integer not divisible by p.

linear congruential method: a method for generating a sequence of pseudo-random numbers based on a congruence of the form $x_{n+1} \equiv ax_n + c \pmod{m}$.

Mersenne prime: a prime of the form $2^p - 1$, where p is a prime.

Möbius function: the arithmetic function $\mu(n)$, where $\mu(n) = 1$ if $n = 1$, $\mu(n) = 0$ if n has a square factor larger than 1, and $\mu(n) = (-1)^s$ if n is square free and is the product of s different primes.

modulus: the integer m in a congruence $a \equiv b\,(\text{mod } m)$.

multiple of an integer a: an integer b such that a divides b.

multiplicative function: a function f such that $f(mn) = f(m)f(n)$ whenever m and n are relatively prime positive integers.

mutually relatively prime (set of integers): integers with no common factor greater than 1.

number field: a field that is a finite degree extension of $\mathcal{Q}$.

number field sieve: a factoring algorithm, currently the best one known for large numbers with no small prime factors.

octal representation of an integer: the base eight representation of this integer.

one's complement expansion: an n bit representation of an integer x with $|x| < 2^{n-1}$, for a specified positive integer n, in which the leftmost bit is 0 if $x \geq 0$ and 1 if $x < 0$, and the remaining $n - 1$ bits are those of the binary expansion of x if $x \geq 0$, and the complements of the bits in the expansion of $|x|$ if $x < 0$.

order of an integer a modulo m: the least positive integer t, denoted by $\text{ord}_m a$, such that $a^t \equiv 1 \pmod{m}$; here $\gcd(a, m) = 1$.

pairwise relatively prime: integers with the property that each two of them are relatively prime.

palindrome: a finite sequence that reads the same forward and backward.

partial quotient: a term a_i of a continued fraction.

Pell's equation: the diophantine equation $x^2 - dy^2 = 1$, where d is a positive integer that is not a perfect square.

perfect number: a positive integer whose sum of positive divisors, other than the integer itself, equals this integer.

periodic base b expansion: a base b expansion in which the terms beyond a certain point are repetitions of the same block of integers.

powerful integer: an integer n with the property that p^2 divides n whenever p is a prime that divides n.

primality test: an algorithm that determines whether a positive integer is prime.

prime: a positive integer greater than 1 that has exactly two factors, 1 and itself.

prime factorization: the factorization of an integer into primes.

prime number theorem: the theorem that states that the number of primes not exceeding a positive real number x is asymptotic to $\frac{x}{\log x}$ (where $\log x$ denotes the natural logarithm of x).

prime-power factorization: the factorization of an integer into powers of distinct primes.

primitive root of an integer n: an integer r such that the least positive residues of the powers of r run through all positive integers relatively prime to n and less than n.

probabilistic primality test: an algorithm that determines whether an integer is prime with a small probability of a false positive result.

pseudoprime to the base b: a composite positive integer n such that $b^n \equiv b \pmod{n}$.

pseudo-random number generator: a deterministic method to generate numbers that share many properties with numbers really chosen randomly.

Pythagorean triple: positive integers x, y, and z such that $x^2 + y^2 = z^2$.

quadratic field: the set of numbers $Q(\sqrt{d}) = \{a + b\sqrt{d} \mid a, b \text{ rational}\}$ for some square-free integer d.

quadratic irrational: an irrational number that is the root of a quadratic polynomial with integer coefficients.

quadratic nonresidue (of m): an integer that is not a perfect square modulo m.

quadratic reciprocity: the law that states that given two odd primes p and q, if at least one of them is of the form $4n + 1$, then p is a quadratic residue of q if and only if q is a quadratic residue of p and if both primes are of the form $4n + 3$, then p is a quadratic residue of q if and only if q is a quadratic nonresidue of p.

quadratic residue (of m): an integer that is a perfect square modulo m.

quadratic sieve: a factoring algorithm invented by Pomerance in 1981.

rational number: a real number that is the ratio of two integers. The set of rational numbers is denoted $\mathcal{Q}$.

reduced system of residues modulo m: pairwise incongruent integers modulo m such that each integer in the set is relatively prime to m and every integer relatively prime to m is congruent to an integer in the set.

relatively prime (integers): two integers with no common divisor greater than 1; see *coprime*.

remainder (of the integer a when divided by the positive integer d): the integer r in the equation $a = dq + r$ with $0 \le r < d$, written $r = a \textbf{ mod } d$.

root (of a function f modulo m): an integer r such that $f(r) \equiv 0 \pmod{m}$.

sieve of Eratosthenes: a procedure for finding all primes less than a specified integer.

smooth number: an integer all of whose prime divisors are small.

square root (of a modulo m): an integer r whose square is congruent to a modulo m.

square-free integer: an integer not divisible by any perfect square other than 1.

ten most wanted numbers: a collection of large integers on a list, maintained by a group of researchers, whose currently unknown factorizations are actively sought; these integers are somewhat beyond the realm of numbers that can be factored using known techniques.

terminating base-b expansion: a base-b expansion with only a finite number of nonzero coefficients.

totient function: the Euler phi-function.

transcendental number: a complex number that cannot be expressed as the root of an algebraic equation with integer coefficients.

trial division: a factorization technique that proceeds by dividing an integer by successive primes.

twin primes: a pair of primes that differ by two.

two's complement expansion: an n bit representation of an integer x, with $-2^{n-1} \leq x \leq 2^{n-1}-1$, for a specified positive integer n, in which the leftmost bit is 0 if $x \geq 0$ and 1 if $x < 0$, and the remaining $n-1$ bits are those from the binary expansion of x if $x \geq 0$ and are those of the binary expansion of $2^n - |x|$ if $x < 0$.

ultimately periodic: a sequence (typically a base-k expansion or continued fraction) $(a_i)_{i\geq 0}$ that eventually repeats; that is, there exist k and N such that $a_{n+k} = a_n$ for all $n \geq N$.

unit (of a number field): an algebraic integer that divides 1 in this field.

Waring's problem: the problem of determining the smallest number $g(k)$ such that every integer is the sum of $g(k)$ kth powers of integers.

4.1 BASIC CONCEPTS

The basic concepts of number theory include the classification of numbers into different sets of special importance, the notion of divisibility, and the representation of integers. For more information about these basic concepts, see introductory number theory texts, such as [Ro10].

Unless otherwise specified, log will indicate the natural logarithm function.

4.1.1 NUMBERS

Definitions:

The ***integers*** are the elements of the set $\mathcal{Z} = \{\ldots, -3, -2, -1, 0, 1, 2, 3, \ldots\}$.

The ***natural numbers*** are the integers in the set $\mathcal{N} = \{0, 1, 2, 3, \ldots\}$.

The ***rational numbers*** are real numbers that can be written as a/b where a and b are integers with $b \neq 0$. Numbers that are not rational are called ***irrational***. The set of rational numbers is denoted by $\mathcal{Q}$.

The ***algebraic numbers*** are real numbers that are solutions of equations of the form $a_n x^n + \cdots + a_1 x + a_0 = 0$, where a_i is an integer for $i = 0, 1, \ldots, n$. Real numbers that are not algebraic are called ***transcendental***.

Facts:

1. The following table summarizes information and notation about some important types of numbers.

name	*definition*	*examples*
natural numbers $\mathcal{N}$	$\{0, 1, 2, \ldots\}$	0, 43
integers $\mathcal{Z}$	$\{\ldots, -2, -1, 0, 1, 2, \ldots\}$	0, 43, -314
Gaussian integers $\mathcal{Z}[i]$	$\{a + bi \mid a, b \in \mathcal{Z}\}$	3, $4 + 3i$, $7i$
rational numbers $\mathcal{Q}$	$\{\frac{a}{b} \mid a, b \in \mathcal{Z}; b \neq 0\}$	0, $\frac{22}{7}$
quadratic irrationals	irrational root of quadratic equation $a_2x^2 + a_1x + a_0 = 0$; all $a_i \in \mathcal{Q}$	$\sqrt{2}$, $\frac{2+\sqrt{5}}{3}$
irrational numbers	$\mathcal{R} - \mathcal{Q}$	$\sqrt{2}$, π, e
algebraic numbers $\overline{\mathcal{Q}}$	root of algebraic equation $a_nx^n + \cdots + a_0 = 0$, $n \geq 1$, $a_0, \ldots, a_n \in \mathcal{Z}$	i, $\sqrt{2}$, $\sqrt[3]{\frac{3}{2}}$
algebraic integers $\mathcal{A}$	root of *monic* algebraic equation $x^n + a_{n-1}x^{n-1} + \cdots + a_0 = 0$, $n \geq 1$, $a_0, a_1, \ldots, a_{n-1} \in \mathcal{Z}$	i, $\sqrt{2}$, $\frac{1+\sqrt{5}}{2}$
transcendental numbers	$\mathcal{C} - \overline{\mathcal{Q}}$	π, e, $i \log 2$
real numbers $\mathcal{R}$	completion of $\mathcal{Q}$	0, $\frac{1}{3}$, $\sqrt{2}$, π
complex numbers $\mathcal{C}$	$\overline{\mathcal{R}}$ or $\mathcal{R}[i]$	$3 + 2i$, $e + i\pi$

2. Some sources do not include 0 in the set of natural numbers. So, always check the definition of natural numbers used in your sources.

3. A real number is rational if and only if its decimal expansion terminates or is periodic. (See §4.1.3).

4. The number $N^{1/m}$ is irrational where N and m are positive integers, unless N is the mth power of an integer n.

5. The number $\log_b a$ is irrational, where a and b are positive integers greater than 1, if there is a prime that divides exactly one of a and b.

6. If x is a root of an equation $x^m + a_{m-1}x^{m-1} + \cdots + a_0 = 0$ in which the coefficients a_i ($i = 0, 1, \ldots, m-1$) are integers, then x is either integer or irrational.

7. The set of algebraic numbers is countable (§1.2.3). Hence, almost all real numbers are transcendental. (However, showing a particular number of interest is transcendental is usually difficult.)

8. Both e and π are transcendental. The transcendence of e was proven by Hermite in 1873, and π was proven transcendental by Lindemann in 1882. Proofs of the transcendence of e and π can be found in [HaWr08].

9. *Gelfond-Schneider theorem*: If α and β are algebraic numbers with α not equal to 0 or 1 and β irrational, then α^β is transcendental. (For a proof see [Ba90].)

10. *Baker's linear forms in logarithms*: If $\alpha_1, \ldots, \alpha_n$ are nonzero algebraic numbers and $\log \alpha_1, \ldots, \log \alpha_n$ are linearly independent over $\mathcal{Q}$, then $1, \log \alpha_1, \ldots, \log \alpha_n$ are linearly independent over $\overline{\mathcal{Q}}$, where $\overline{\mathcal{Q}}$ is the closure of $\mathcal{Q}$. (Consult [Ba90] for a proof and applications of this theorem.)

Examples:

1. The numbers $\frac{11}{17}$, $-\frac{3345}{7}$, -1, $\frac{578}{579}$, and 0 are rational.

2. The number $\log_2 10$ is irrational.

3. The numbers $\sqrt{2}$, $1 + \sqrt{2}$, and $\frac{1+\sqrt{2}}{5}$ are irrational.

4. The number $x = 0.10100100010000\ldots$, with a decimal expansion consisting of blocks where the nth block is a 1 followed by n 0s, is irrational, since this decimal expansion does not terminate and is not periodic.

5. The decimal expansion of $\frac{22}{7}$ is periodic, since $\frac{22}{7} = 3.\overline{142857}$. However, the decimal expansion of π neither terminates, nor is periodic, with $\pi = 3.141592653589793\ldots$.

6. It is not known whether Euler's constant $\gamma = \lim\limits_{n\to\infty}\left(\sum_{k=1}^{n}\frac{1}{k} - \log n\right)$ (where $\log x$ denotes the natural logarithm of x) is rational or irrational.

7. The numbers 2, $\frac{1}{2}$, $\sqrt{17}$, $\sqrt[3]{5}$, and $1 + \sqrt[6]{2}$ are algebraic.

8. By the Gelfond-Schneider theorem (Fact 9), $\sqrt{2}^{\sqrt{2}}$ is transcendental.

9. By Baker's linear forms in logarithms theorem (Fact 10), since $\log_2 10$ is irrational, it is transcendental.

4.1.2 DIVISIBILITY

The notion of the divisibility of one integer by another is the most basic concept in number theory. Introductory number theory texts, such as [HaWr08], [NiZuMo91], and [Ro10], are good references for this material.

Definitions:

Suppose a and d are integers with $d > 0$. Then in the equation $a = dq + r$ with $0 \le r < d$, a is the ***dividend***, d is the ***divisor***, q is the ***quotient***, and r is the ***remainder***.

Let m and n be integers with $m \ge 1$ and $n = dm + r$ with $0 \le r < m$. Then $n \,\mathbf{mod}\, m$, the value of the **mod** m function at n, is r, the remainder when n is divided by m.

If a and b are integers and $a \ne 0$, then a ***divides*** b, written $a|b$, if there is an integer c such that $b = ac$. If a divides b, then a is a ***factor*** or ***divisor*** of b, and b is a ***multiple*** of a. If a is a positive divisor of b that does not equal b, then a is a ***proper divisor*** of b. The notation $a \not| \, b$ means that a does not divide b.

A ***prime*** is a positive integer divisible by exactly two distinct positive integers, 1 and itself. A positive integer, other than 1, that is not prime is called ***composite***.

An integer is ***square free*** if it is not divisible by any perfect square other than 1.

An integer n is ***powerful*** if whenever a prime p divides n, p^2 divides n.

If p is prime and n is a positive integer, then p^r ***exactly divides*** n, written $p^r||n$, if p^r divides n, but p^{r+1} does not divide n.

Facts:

1. If a is a nonzero integer, then $a|0$.

2. If a is an integer, then $1|a$.

3. If a and b are positive integers and $a|b$, then the following statements are true:

- $a \le b$;
- $\frac{b}{a}$ divides b;
- a^k divides b^k for every positive integer k;
- a divides bc for every integer c.

4. If a, b, and c are integers such that $a|b$ and $b|c$, then $a|c$.

5. If a, b, and c are integers such that $a|b$ and $a|c$, then $a|bm+cn$ for all integers m and n.

6. If a and b are integers such that $a|b$ and $b|a$, then $a = \pm b$.

7. If a and b are integers and m is a nonzero integer, then $a|b$ if and only if $ma|mb$.

8. *Division algorithm*: If a and d are integers with d positive, then there are unique integers q and r such that $a = dq + r$ with $0 \le r < d$. (*Note*: The division algorithm is not an algorithm, in spite of its name.)

9. The quotient q and remainder r when the integer a is divided by the positive integer d are given by $q = \lfloor \frac{a}{d} \rfloor$ and $r = a - d \lfloor \frac{a}{d} \rfloor$, respectively.

10. If a and d are positive integers, then there are unique integers q, r, and e such that $a = dq + er$ where $e = \pm 1$ and $-\frac{d}{2} < r \le \frac{d}{2}$.

11. There are several divisibility tests that are easily performed using the decimal expansion of an integer. These include:

- An integer is divisible by 2 if and only if its last digit is even. It is divisible by 4 if and only if the integer made up of its last two digits is divisible by four. More generally, it is divisible by 2^j if and only if the integer made up of the last j decimal digits of n is divisible by 2^j.
- An integer is divisible by 5 if and only if its last digit is divisible by 5 (which means it is either 0 or 5). It is divisible by 25 if and only if the integer made up of the last two digits is divisible by 25. More generally, it is divisible by 5^j if and only if the integer made up of the last j digits of n is divisible by 5^j.
- An integer is divisible by 3, or by 9, if and only if the sum of the decimal digits of n is divisible by 3, or by 9, respectively.
- An integer is divisible by 11 if and only if the integer formed by alternately adding and subtracting the decimal digits of the integer is divisible by 11.
- An integer is divisible by 7, 11, or 13 if and only if the integer formed by successively adding and subtracting the three-digit integers formed from successive blocks of three decimal digits of the original number, where digits are grouped starting with the rightmost digit, is divisible by 7, 11, or 13, respectively.

12. If $d|b-1$, then $n = (a_k \ldots a_1 a_0)_b$ (this notation is defined in §4.1.3) is divisible by d if and only if the sum of the base b digits of n, $a_k + \cdots + a_1 + a_0$, is divisible by d.

13. If $d|b+1$, then $n = (a_k \ldots a_1 a_0)_b$ is divisible by d if and only if the alternating sum of the base b digits of n, $(-1)^k a_k + \cdots - a_1 + a_0$, is divisible by d.

14. If $p^r || a$ and $p^s || b$, where p is a prime and a and b are positive integers, then $p^{r+s} || ab$.

15. If $p^r || a$ and $p^s || b$, where p is a prime and a and b are positive integers, then $p^{\min(r,s)} || a + b$.

16. There are infinitely many primes. (See §4.4.2.)

17. There are efficient algorithms that can produce large integers that have an extremely high probability of being prime. (See §4.4.4.)

18. *Fundamental theorem of arithmetic*: Every positive integer can be written as the product of primes in exactly one way, where the primes occur in nondecreasing order in the factorization.

19. Many different algorithms have been devised to find the factorization of a positive integer into primes. Using some recently invented algorithms and the powerful computer systems available today, it is feasible to factor integers with over 100 digits. (See §4.5.1.)

20. The relative ease of producing large primes compared with the apparent difficulty of factoring large integers is the basis for an important cryptosystem called RSA. (See Chapter 15.)

Examples:

1. The integers 0, 3, −12, 21, 342, and −1,113 are divisible by 3; the integers −1, 7, 29, and −1,111 are not divisible by 3.

2. The quotient and remainder when 214 is divided by 6 are 35 and 4, respectively, since $214 = 35 \cdot 6 + 4$.

3. The quotient and remainder when −114 is divided by 7 are −17 and 5, respectively, since $-114 = -17 \cdot 7 + 5$.

4. With $a = 214$ and $d = 6$, the expansion of Fact 10 is $214 = 36 \cdot 6 - 2$ (so that $e = -1$ and $r = 2$).

5. $11 \textbf{ mod } 4 = 3$, $100 \textbf{ mod } 7 = 2$, and $-22 \textbf{ mod } 5 = 3$.

6. The following are primes: 2, 3, 17, 101, 641. The following are composites: 4, 9, 91, 111, 1001.

7. The integers 15, 105, and 210 are square free; the integers 12, 99, and 270 are not.

8. The integer 72 is powerful since 2 and 3 are the only primes that divide 72 and $2^2 = 4$ and $3^2 = 9$ both divide 72, but 180 is not powerful since 5 divides 180, but 5^2 does not.

9. The integer 32,688,048 is divisible by 2, 4, 8, and 16 since $2|8$, $4|48$, $8|048$, and $16|8{,}048$, but it is not divisible by 32 since 32 does not divide 88,048.

10. The integer 723,160,823 is divisible by 11 since the alternating sum of its digits, $3 - 2 + 8 - 0 + 6 - 1 + 3 - 2 + 7 = 22$, is divisible by 11.

11. Since $3^3|216$, but $3^4 \not| 216$, it follows that $3^3||216$.

4.1.3 RADIX REPRESENTATIONS

The representation of numbers in different bases has been important in the development of mathematics from its earliest days and is extremely important in computer arithmetic. For further details on this topic, see [Kn97], [Ko93], and [Sc85].

Definitions:

The ***base b expansion*** of a positive integer n, where b is an integer greater than 1, is the unique expansion of n as $n = a_k b^k + a_{k-1} b^{k-1} + \cdots + a_1 b + a_0$; here k is a nonnegative integer, a_j is a nonnegative integer less than b for $j = 0, 1, \ldots, k$, and the initial coefficient $a_k \neq 0$. This expansion is written as $(a_k a_{k-1} \ldots a_1 a_0)_b$.

The integer b in the base b expansion of an integer is called the ***base*** or ***radix*** of the expansion.

The coefficients a_j in the base b expansion of an integer are called the base b ***digits*** of the expansion.

Base 10 expansions are called ***decimal*** expansions. The digits are called ***decimal digits***.

Base 2 expansions are called ***binary*** expansions. The digits are called ***binary digits*** or ***bits***.

Base 8 expansions are called ***octal*** expansions.

Base 16 expansions are called ***hexadecimal*** expansions. The 16 hexadecimal digits are $0, 1, 2, 3, 4, 5, 6, 7, 8, 9, \mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}$ (where $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}$ correspond to the decimal numbers $10, 11, 12, 13, 14, 15$, respectively).

The ***binary coded decimal*** expansion of an integer is the bit string formed by replacing each digit in the decimal expansion of the integer by the four bit binary expansion of that digit.

The ***one's complement*** expansion of an integer x with $|x| < 2^{n-1}$, for a specified positive integer n, uses n bits, where the leftmost bit is 0 if $x \geq 0$ and 1 if $x < 0$, and the remaining $n-1$ bits are those from the binary expansion of x if $x \geq 0$ and are the complements of the bits in the binary expansion of $|x|$ if $x < 0$. (*Note*: The one's complement representation $11\ldots1$, consisting of n 1s, is usually considered to be the negative representation of the number 0.)

The ***two's complement*** expansion of an integer x with $-2^{n-1} \leq x \leq 2^{n-1}-1$, for a specified positive integer n, uses n bits, where the leftmost bit is 0 if $x \geq 0$ and 1 if $x < 0$, and the remaining $n-1$ bits are those from the binary expansion of x if $x \geq 0$ and are those of the binary expansion of $2^n - |x|$ if $x < 0$.

The ***base b expansion*** (where b is an integer greater than 1) of a real number x with $0 \leq x < 1$ is the unique expansion of x as $x = \sum_{j=1}^{\infty} \frac{c_j}{b^j}$ where c_j is a nonnegative integer less than b for $j = 1, 2, ...$ and for every integer N there is a coefficient $c_n \neq b-1$ for some $n > N$. This expansion is written as $(.c_1c_2c_3\ldots)_b$.

A base b expansion $(.c_1c_2c_3\ldots)_b$ ***terminates*** if there is a positive integer n such that $c_n = c_{n+1} = c_{n+2} = \cdots = 0$.

A base b expansion $(.c_1c_2c_3\ldots)_b$ is ***periodic*** if there are positive integers N and k such that $c_{n+k} = c_n$ for all $n \geq N$.

The ***periodic base b expansion*** $(.c_1c_2\ldots c_{N-1}c_N\ldots c_{N+k-1}c_N\ldots c_{N+k-1}c_N\ldots)_b$ is denoted by $(.c_1c_2\ldots c_{N-1}\overline{c_N\ldots c_{N+k-1}})_b$. The part of the periodic base b expansion preceding the periodic part is the ***pre-period*** and the periodic part is the ***period***, where the period and pre-period are taken to have minimal possible length.

Facts:

1. If b is a positive integer greater than 1, then every positive integer n has a unique base b expansion.

2. *Converting from base 10 to base b*: Take the positive integer n and divide it by b to obtain $n = bq_0 + a_0$, $0 \leq a_0 < b$. Then divide q_0 by b to obtain $q_0 = bq_1 + a_1$, $0 \leq a_1 < b$. Continue this process, successively dividing the quotients by b, until a quotient of zero is obtained, after k steps. The base b expansion of n is then $(a_{k-1}\ldots a_1a_0)_b$. (See Algorithm 1.)

Algorithm 1: **Constructing base *b* expansions.**

```
procedure base b expansion(n: positive integer)
  $q := n$
  $k := 0$
  while $q \neq 0$
    $a_k := q$ mod $b$
    $q := \lfloor \frac{q}{b} \rfloor$
```

```
        $k := k + 1$
    {The base $b$ expansion of $n$ is $(a_{k-1} \dots a_1 a_0)_b$}
```

3. *Converting from base* 2 *to base* 2^k: Group the bits in the base 2 expansion into blocks of k bits, starting from the right, and then convert each block of k bits into a base 2^k digit. For example, converting from binary (base 2) to octal (base 8) is done by grouping the bits of the binary expansion into blocks of three bits starting from the right and converting each block into an octal digit. Similarly, converting from binary to hexadecimal (base 16) is done by grouping the bits of the binary expansion into blocks of four bits starting from the right and converting each block into a hex digit.

4. *Converting from base* 2^k *to binary (base 2)*: convert each base 2^k digit into a block of k bits and string together these bits in the order the original digits appear. For example, to convert from hexadecimal to binary, convert each hex digit into the block of four bits that represent this hex digit and then string together these blocks of four bits in the correct order.

5. Every positive integer can be expressed uniquely as the sum of distinct powers of 2. This follows since every positive integer has a unique base 2 expansion, with the digits either 0 or 1.

6. There are $\lfloor \log_b n \rfloor + 1$ decimal digits in the base b expansion of the positive integer n.

7. The number x with one's complement representation $(a_{n-1}a_{n-2} \dots a_1 a_0)$ can be found using the equation

$$x = -a_{n-1}(2^{n-1}-1) + \sum_{i=0}^{n-2} a_i 2^i.$$

8. The number x with two's complement representation $(a_{n-1}a_{n-2} \dots a_1 a_0)$ can be found using the equation

$$x = -a_{n-1} \cdot 2^{n-1} + \sum_{i=0}^{n-2} a_i 2^i.$$

9. Two's complement representations of integers are often used by computers because addition and subtraction of integers, where these integers may be either positive or negative, can be performed easily using these representations.

10. Define a function $\mathrm{Lg}\, n$ by the rule

$$\mathrm{Lg}\, n = \begin{cases} 1 & \text{if } n = 0; \\ 1 + \lfloor \log_2 |n| \rfloor & \text{if } n \neq 0. \end{cases}$$

Then $\mathrm{Lg}\, n$ is the number of bits in the base 2 expansion of n, not counting the sign bit. (Compare with Fact 6.)

11. The bit operations for the basic operations are given in the following table, adapted from [BaSh96]. This table displays the number of bit operations used by the standard, naive algorithms, doing things bit by bit (addition with carries, subtraction with borrows, standard multiplication by each bit and shifting and adding, and standard division), and a big-oh estimate for the number of bits required to do the operations using the algorithm with the currently best known computational complexity. (The function Lg is defined in Fact 10; the function $\mu(m, n)$ is defined by the rule $\mu(m, n) = m(\mathrm{Lg}\, n)(\mathrm{Lg}\,\mathrm{Lg}\, n)$ if $m \geq n$ and $\mu(m, n) = n(\mathrm{Lg}\, m)(\mathrm{Lg}\,\mathrm{Lg}\, m)$ otherwise.)

operations	*number of bits for operation (following naive algorithm)*	*best known complexity (sophisticated algorithm)*
$a \pm b$	$\text{Lg}\, a + \text{Lg}\, b$	$O(\text{Lg}\, a + \text{Lg}\, b)$
$a \cdot b$	$\text{Lg}\, a \cdot \text{Lg}\, b$	$O(\mu(\text{Lg}\, a, \text{Lg}\, b))$
$a = qb + r$	$\text{Lg}\, q \cdot \text{Lg}\, b$	$O(\mu(\text{Lg}\, q, \text{Lg}\, b))$

12. If b is a positive integer greater than 1 and x is a real number with $0 \leq x < 1$, then x can be uniquely written as $x = \sum_{j=1}^{\infty} \frac{c_j}{b^j}$ where c_j is a nonnegative integer less than b for all j, with the restriction that for every positive integer N there is an integer n with $n > N$ and $c_n \neq b - 1$ (in other words, it is not the case that from some point on, all the coefficients are $b - 1$).

13. A periodic or terminating base b expansion, where b is a positive integer, represents a rational number.

14. The base b expansion of a rational number, where b is a positive integer, either terminates or is periodic.

15. If $0 < x < 1$, $x = \frac{r}{s}$ where r and s are relatively prime positive integers, and $s = TU$ where every prime factor of T divides b and $\gcd(U, b) = 1$, then the period length of the base b expansion of x is $\text{ord}_U b$ (defined in §4.7.1) and the pre-period length is the smallest positive integer N such that T divides b^N.

16. The period length of the base b expansion of $\frac{1}{m}$ (b and m positive integers greater than 1) is $m - 1$ if and only if m is prime and b is a primitive root of m. (See §4.7.1.)

Examples:

1. The binary (base 2), octal (base 8), and hexadecimal (base 16) expansions of the integer 2001 are $(11111010001)_2$, $(3721)_8$, and $(7D1)_{16}$, respectively. The octal and hexadecimal expansions can be obtained from the binary expansion by grouping together, from the right, the bits of the binary expansion into groups of three bits and four bits, respectively.

2. The hexadecimal expansion $2FB3$ can be converted to a binary expansion by replacing each hex digit by a block of four bits to give 10111110110011. (The initial two 0s in the four-bit expansion of the initial hex digit 2 are omitted.)

3. The binary coded decimal expansion of 729 is 011100101001.

4. The nine-bit one's complement expansions of 214 and -113 (taking $n = 9$ in the definition) are 011010110 and 110001110.

5. The nine-bit two's complement expansions of 214 and -113 (taking $n = 9$ in the definition) are 011010110 and 110001111.

6. By Fact 7 the integer with a nine-bit one's complement representation of 101110111 equals $-1(256 - 1) + 119 = -136$.

7. By Fact 8 the integer with a nine-bit two's complement representation of 101110111 equals $-256 + 119 = -137$.

8. By Fact 15 the pre-period of the decimal expansion of $\frac{5}{28}$ has length 2 and the period has length 6 since $28 = 4 \cdot 7$ and $\text{ord}_7 10 = 6$. This is verified by noting that $\frac{5}{28} = (.17\overline{857142})_{10}$.

4.2 GREATEST COMMON DIVISORS

The concept of the greatest common divisor of two integers plays an important role in number theory. The Euclidean algorithm, an algorithm for computing greatest common divisors, was known in ancient times and was one of the first algorithms that was studied for what is now called its computational complexity. The Euclidean algorithm and its extensions are used extensively in number theory and its applications, including those to cryptography. For more information about the contents of this section consult [HaWr08], [NiZuMo91], or [Ro10].

4.2.1 INTRODUCTION

Definitions:

The ***greatest common divisor*** of the integers a and b, not both zero, written $\gcd(a, b)$, is the largest integer that divides both a and b.

The integers a and b are ***relatively prime*** (or ***coprime***) if they have no positive divisors in common other than 1, i.e., if $\gcd(a, b) = 1$.

The ***greatest common divisor*** of the integers a_i, $i = 1, 2, \ldots, k$, not all zero, written $\gcd(a_1, a_2, \ldots, a_k)$, is the largest integer that divides all the integers a_i.

The integers $a_1, a_2, \ldots, a_k$ are ***pairwise relatively prime*** if $\gcd(a_i, a_j) = 1$ for $i \neq j$.

The integers $a_1, a_2, \ldots, a_k$ are ***mutually relatively prime*** if $\gcd(a_1, a_2, \ldots, a_k) = 1$.

The ***least common multiple*** of nonzero integers a and b, written $\operatorname{lcm}(a, b)$, is the smallest positive integer that is a multiple of both a and b.

The ***least common multiple*** of nonzero integers $a_1, \ldots, a_k$, written $\operatorname{lcm}(a_1, \ldots, a_k)$, is the smallest positive integer that is a multiple of all the integers a_i, $i = 1, 2, \ldots, k$.

The ***Farey series of order n*** is the set of fractions $\frac{h}{k}$ in which h and k are integers, $0 \leq h \leq k \leq n$, $k \neq 0$, and $\gcd(h, k) = 1$, in ascending order, with 0 and 1 included in the forms $\frac{0}{1}$ and $\frac{1}{1}$, respectively.

Facts:

1. If $d|a$ and $d|b$, then $d|\gcd(a, b)$.

2. If $a|m$ and $b|m$, then $\operatorname{lcm}(a, b)|m$.

3. If a is a positive integer, then $\gcd(0, a) = a$.

4. If a and b are positive integers with $a < b$, then $\gcd(a, b) = \gcd(b \textbf{ mod } a, a)$.

5. If a and b are integers with $\gcd(a, b) = d$, then $\gcd(\frac{a}{d}, \frac{b}{d}) = 1$.

6. If a, b, and c are integers, then $\gcd(a + cb, b) = \gcd(a, b)$.

7. If a, b, and c are integers with not both a and b zero and $c \neq 0$, then $\gcd(ac, bc) = |c| \gcd(a, b)$.

8. If a and b are integers with $\gcd(a, b) = 1$, then $\gcd(a + b, a - b) = 1$ or 2. (This greatest common divisor is 2 when both a and b are odd.)

9. If a, b, and c are integers with $\gcd(a, b) = \gcd(a, c) = 1$, then $\gcd(a, bc) = 1$.

10. If a, b, and c are mutually relatively prime nonzero integers, then $\gcd(a, bc) = \gcd(a, b) \cdot \gcd(a, c)$.

11. If a and b are integers, not both zero, then $\gcd(a, b)$ is the least positive integer of the form $ma + nb$ where m and n are integers.

12. The probability that two randomly selected integers are relatively prime is $\frac{6}{\pi^2}$. More precisely, if $R(n)$ equals the number of pairs of integers a, b with $1 \leq a \leq n$, $1 \leq b \leq n$, and $\gcd(a, b) = 1$, then $\frac{R(n)}{n^2} = \frac{6}{\pi^2} + O(\frac{\log n}{n})$.

13. If a and b are positive integers, then $\gcd(2^a - 1, 2^b - 1) = 2^{(a,b)} - 1$.

14. If a, b, and c are integers and $a|bc$ and $\gcd(a, b) = 1$, then $a|c$.

15. If a, b, and c are integers, $a|c$, $b|c$ and $\gcd(a, b) = 1$, then $ab|c$.

16. If $a_1, a_2, \ldots, a_k$ are integers, not all zero, then $\gcd(a_1, \ldots, a_k)$ is the least positive integer that is a linear combination with integer coefficients of $a_1, \ldots, a_k$.

17. If $a_1, a_2, \ldots, a_k$ are integers, not all zero, and $d|a_i$ holds for $i = 1, 2, \ldots, k$, then $d|\gcd(a_1, a_2, \ldots, a_k)$.

18. If $a_1, \ldots, a_n$ are integers, not all zero, then the greatest common divisor of these n integers is the same as the greatest common divisor of the set of $n - 1$ integers made up of the first $n - 2$ integers and the greatest common divisor of the last two. That is, $\gcd(a_1, \ldots, a_n) = \gcd(a_1, \ldots, a_{n-2}, \gcd(a_{n-1}, a_n))$.

19. If a and b are nonzero integers and m is a positive integer, then $\operatorname{lcm}(ma, mb) = m \cdot \operatorname{lcm}(a, b)$

20. If b is a common multiple of the integers $a_1, a_2, \ldots, a_k$, then b is a multiple of $\operatorname{lcm}(a_1, \ldots, a_k)$.

21. The common multiples of the integers $a_1, \ldots, a_k$ are the integers 0, $\operatorname{lcm}(a_1, \ldots, a_k)$, $2 \cdot \operatorname{lcm}(a_1, \ldots, a_k), \ldots$.

22. If $a_1, a_2, \ldots, a_n$ are pairwise relatively prime integers, then $\operatorname{lcm}(a_1, \ldots, a_n) = a_1 a_2 \ldots a_n$.

23. If $a_1, a_2, \ldots, a_n$ are integers, not all zero, then $\operatorname{lcm}(a_1, a_2, \ldots, a_{n-1}, a_n) = \operatorname{lcm}(\operatorname{lcm}(a_1, a_2, \ldots, a_{n-1}), a_n)$.

24. If $a = {p_1}^{a_1} {p_2}^{a_2} \cdots {p_n}^{a_n}$ and $b = {p_1}^{b_1} {p_2}^{a_2} \cdots {p_n}^{b_n}$, where the p_i are distinct primes for $i = 1, \ldots, n$, and each exponent is a nonnegative integer, then

$$\gcd(a, b) = {p_1}^{\min(a_1,b_1)} {p_2}^{\min(a_2,b_2)} \ldots {p_n}^{\min(a_n,b_n)},$$

where $\min(x, y)$ denotes the minimum of x and y, and

$$\operatorname{lcm}(a, b) = {p_1}^{\max(a_1,b_1)} {p_2}^{\max(a_2,b_2)} \ldots {p_n}^{\max(a_n,b_n)},$$

where $\max(x, y)$ denotes the maximum of x and y.

25. If a and b are positive integers, then $ab = \gcd(a, b) \cdot \operatorname{lcm}(a, b)$.

26. If a, b, and c are positive integers, then $\operatorname{lcm}(a, b, c) = \dfrac{abc \cdot \gcd(a, b, c)}{\gcd(a, b) \cdot \gcd(a, c) \cdot \gcd(b, c)}$.

27. If a, b, and c are positive integers, then $\gcd(\operatorname{lcm}(a, b), \operatorname{lcm}(a, c)) = \operatorname{lcm}(a, \gcd(b, c))$ and $\operatorname{lcm}(\gcd(a, b), \gcd(a, c)) = \gcd(a, \operatorname{lcm}(b, c))$.

28. If $\frac{a}{b}$, $\frac{c}{d}$, and $\frac{e}{f}$ are successive terms of a Farey series, then $\frac{c}{d} = \frac{a+e}{b+f}$.

29. If $\frac{a}{b}$ and $\frac{c}{d}$ are successive terms of a Farey series, then $ad - bc = -1$.

30. If $\frac{a}{b}$ and $\frac{c}{d}$ are successive terms of a Farey series of order n, then $b + d > n$.

31. Farey series are named after an English geologist who published a note describing their properties in the *Philosophical Magazine* in 1816. The eminent French mathematician Cauchy supplied proofs of the properties stated, but not proved, by Farey. Also, according to [Di71], these properties had been stated and proved by Haros in 1802.

Examples:

1. $\gcd(12, 15) = 3$, $\gcd(14, 25) = 1$, $\gcd(0, 100) = 100$, and $\gcd(3, 39) = 3$.

2. $\gcd(2^7 3^3 5^4 7^2 11^3 17^3, 2^4 3^5 5^2 7^2 11^2 13^3) = 2^4 3^3 5^2 7^2 11^2$.

3. $\mathrm{lcm}(2^7 3^3 5^4 7^2 11^3 17^3, 2^4 3^5 5^2 7^2 11^2 13^3) = 2^7 3^5 5^4 7^2 11^3 13^3 17^3$.

4. $\gcd(18, 24, 36) = 6$ and $\gcd(10, 25, 35, 245) = 5$.

5. The integers 15, 21, and 35 are mutually relatively prime since $\gcd(15, 21, 35) = 1$. However, they are not pairwise relatively prime since $\gcd(15, 35) = 5$.

6. The integers 6, 35, and 143 are both mutually relatively prime and pairwise relatively prime.

7. The Farey series of order 5 is $\frac{0}{1}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{2}{5}, \frac{1}{2}, \frac{3}{5}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{1}{1}$.

4.2.2 THE EUCLIDEAN ALGORITHM

Finding the greatest common divisor of two integers is one of the most common problems in number theory and its applications. An algorithm for this task was known in ancient times by Euclid. His algorithm and its extensions are among the most commonly used algorithms. For more information about these algorithms see [BaSh96] and [Kn97].

Definition:

The ***Euclidean algorithm*** is an algorithm that computes the greatest common divisor of two integers a and b with $a \leq b$, by replacing them with a and b **mod** a, and repeating this step until one of the integers reached is zero.

Facts:

1. *The Euclidean algorithm*: The greatest common divisor of two positive integers can be computed using the recurrence given in §4.2.1, Fact 4 together with §4.1.2, Fact 3. The resulting algorithm proceeds by successively replacing a pair of positive integers with a new pair of integers formed from the smaller of the two integers and the remainder when the larger is divided by the smaller, stopping once a zero remainder is reached. The last nonzero remainder is the greatest common divisor of the original two integers. (See Algorithm 1.)

Algorithm 1: **The Euclidean algorithm.**

```
procedure gcd(a, b: positive integers)
  $r_0 := a$; $r_1 := b$
  $i := 1$
  while $r_i \neq 0$
    $r_{i+1} := r_{i-1}$ mod $r_i$
    $i := i + 1$
{gcd(a, b) is $r_{i-1}$}
```

2. *Lamé's theorem*: The number of divisions needed to find the greatest common divisor of two positive integers using the Euclidean algorithm does not exceed five times the number of decimal digits in the smaller of the two integers. (This was proved by Gabriel Lamé (1795–1870).) (See [BaSh96] or [Ro10] for a proof.)

3. The Euclidean algorithm finds the greatest common divisor of the Fibonacci numbers (§3.1.2) F_{n+1} and F_{n+2} (where n is a positive integer) using exactly n division steps. If the Euclidean algorithm uses exactly n division steps to find the greatest common divisor of the positive integers a and b (with $a < b$), then $a \geq F_{n+1}$ and $b \geq F_{n+2}$.

4. The Euclidean algorithm uses $O((\log b)^3)$ bit operations to find the greatest common divisor of two integers a and b with $a < b$.

5. The Euclidean algorithm uses $O(\mathrm{Lg}\, a \cdot \mathrm{Lg}\, b)$ bit operations to find the greatest common divisor of two integers a and b.

6. *Least remainder Euclidean algorithm*: The greatest common divisor of two integers a and b (with $a < b$) can be found by replacing a and b with a and the least remainder of b when divided by a. (The *least remainder* of b when divided by a is the integer of smallest absolute value congruent to b modulo a. It equals b **mod** a if b **mod** $a \leq \frac{a}{2}$, and $(b \textbf{ mod } a) - a$ if b **mod** $a > \frac{a}{2}$.) Repeating this procedure until a remainder of zero is reached produces the greatest common divisor of a and b as the last nonzero remainder.

7. The number of divisions used by the least remainder Euclidean algorithm to find the greatest common divisor of two integers is less than or equal to the number of divisions used by the Euclidean algorithm to find this greatest common divisor.

8. *Binary greatest common divisor algorithm*: The greatest common divisor of two integers a and b can also be found using an algorithm known as the *binary greatest common divisor algorithm*. It is based on the following reductions: if a and b are both even, then $\gcd(a,b) = 2\gcd(\frac{a}{2}, \frac{b}{2})$; if a is even and b is odd, then $\gcd(a,b) = \gcd(\frac{a}{2}, b)$ (and if a is odd and b is even, switch them); and if a and b are both odd, then $\gcd(a,b) = \gcd(\frac{|a-b|}{2}, b)$. To stop, the algorithm uses the rule that $\gcd(a,a) = a$.

9. *Extended Euclidean algorithm*: The extended Euclidean algorithm finds $\gcd(a,b)$ and expresses it in the form $\gcd(a,b) = ma + nb$ for some integers m and n. The two-pass version proceeds by first working through the steps of the Euclidean algorithm to find $\gcd(a,b)$, and then working backwards through the steps to express $\gcd(a,b)$ as a linear combination of each pair of successive remainders until the original integers a and b are reached. The one-pass version of this algorithm keeps track of how each successive remainder can be expressed as a linear combination of successive remainders. When the last step is reached both $\gcd(a,b)$ and integers m and n with $\gcd(a,b) = ma + nb$ are produced. The one-pass version is displayed as Algorithm 2.

Algorithm 2: **The extended Euclidean algorithm.**

```
procedure gcdex($a, b$: positive integers)
  $r_0 := a$; $r_1 := b$
  $m_0 := 1$; $m_1 = 0$
  $n_0 := 0$; $n_1 := 1$
  $i := 1$
  while $r_i \neq 0$
    $r_{i+1} := r_{i-1}$ mod $r_i$
    $m_{i+1} := m_{i-1} - \lfloor \frac{r_{i-1}}{r_i} \rfloor m_i$
```

```
        $n_{i+1} := n_{i-1} - \lfloor \frac{r_{i-1}}{r_i} \rfloor n_i$
        $i := i + 1$
    $\{\gcd(a,b)$ is $r_{i-1}$ and $\gcd(a,b) = m_{i-1}a + n_{i-1}b\}$
```

Examples:

1. When the Euclidean algorithm is used to find $\gcd(53, 77)$, the following steps result:

$$\begin{aligned} 77 &= 1 \cdot 53 + 24, \\ 53 &= 2 \cdot 24 + 5, \\ 24 &= 4 \cdot 5 + 4, \\ 5 &= 1 \cdot 4 + 1, \\ 4 &= 4 \cdot 1. \end{aligned}$$

This shows that $\gcd(53, 77) = 1$. Working backwards through these steps to perform the two-pass version of the Euclidean algorithm gives

$$\begin{aligned} 1 &= 5 - 1 \cdot 4 \\ &= 5 - 1 \cdot (24 - 4 \cdot 5) \;=\; 5 \cdot 5 - 1 \cdot 24 \\ &= 5 \cdot (53 - 2 \cdot 24) - 1 \cdot 24 \;=\; 5 \cdot 53 - 11 \cdot 24 \\ &= 5 \cdot 53 - 11 \cdot (77 - 1 \cdot 53) \;=\; 16 \cdot 53 - 11 \cdot 77. \end{aligned}$$

2. The steps of the least-remainder algorithm when used to compute $\gcd(57, 93)$ are

$$\gcd(57, 93) = \gcd(57, 21) = \gcd(21, 6) = \gcd(6, 3) = 3.$$

3. The steps of the binary GCD algorithm when used to compute $\gcd(108, 194)$ are

$$\begin{aligned} \gcd(108, 194) &= 2 \cdot \gcd(54, 97) = 2 \cdot \gcd(27, 97) = 2 \cdot \gcd(27, 35) \\ &= 2 \cdot \gcd(4, 35) = 2 \cdot \gcd(2, 35) = 2 \cdot \gcd(1, 35) = 2. \end{aligned}$$

4.3 CONGRUENCES

4.3.1 INTRODUCTION

Definitions:

If m is a positive integer and a and b are integers, then ***a is congruent to b modulo m***, written $a \equiv b \pmod{m}$, if m divides $a - b$. If m does not divide $a - b$, a and b are ***incongruent*** modulo m, written $a \not\equiv b \pmod{m}$.

A ***complete system of residues modulo m*** is a set of integers such that every integer is congruent modulo m to exactly one of the integers in the set.

If m is a positive integer and a is an integer with $a = bm + r$, where $0 \le r \le m - 1$, then r is the ***least nonnegative residue of a modulo m***. When a is not divisible by m, r is the ***least positive residue of a modulo m***.

The ***congruence class of a modulo m*** is the set of integers congruent to a modulo m and is written $[a]_m$. Any integer in $[a]_m$ is called a ***representative*** of this class.

If m is a positive integer and a is an integer relatively prime to m, then $\overline{a}$ is an ***inverse of a modulo m*** if $a\overline{a} \equiv 1 \pmod{m}$. An inverse of a modulo m is also written a^{-1} **mod** m.

If m is a positive integer, then a ***reduced residue system modulo m*** is a set of integers such that every integer relatively prime to m is congruent modulo m to exactly one integer in the set.

If m is a positive integer, the set of congruence classes modulo m is written $\mathcal{Z}_m$. (See §5.2.1.)

If m is a positive integer greater than 1, the set of congruence classes of elements relatively prime to m is written $\mathcal{Z}_m^\star$; that is, $\mathcal{Z}_m^\star = \{[a]_m \in \mathcal{Z}_m \mid \gcd(a,n) = 1\}$. (See §5.2.1.)

Facts:

1. If m is a positive integer and a, b, and c are integers, then

- $a \equiv a \pmod{m}$;
- $a \equiv b \pmod{m}$ if and only if $b \equiv a \pmod{m}$;
- if $a \equiv b \pmod{m}$ and $b \equiv c \pmod{m}$, then $a \equiv c \pmod{m}$.

Consequently, congruence modulo m is an equivalence relation. (See §1.4.2 and §5.2.1.)

2. If m is a positive integer and a is an integer, then m divides a if and only if $a \equiv 0 \pmod{m}$.

3. If m is a positive integer and a and b are integers with $a \equiv b \pmod{m}$, then $\gcd(a,m) = \gcd(b,m)$.

4. If a, b, c, and m are integers with m positive and $a \equiv b \pmod{m}$, then $a + c \equiv b + c \pmod{m}$, $a - c \equiv b - c \pmod{m}$, and $ac \equiv bc \pmod{m}$.

5. If m is a positive integer and a, b, c, and d are integers with $a \equiv b \pmod{m}$ and $c \equiv d \pmod{m}$, then $ac \equiv bd \pmod{m}$.

6. If a, b, c, and m are integers, m is positive, $d = \gcd(c,m)$, and $ac \equiv bc \pmod{m}$, then $a \equiv b \pmod{\frac{m}{d}}$.

7. If a, b, c, and m are integers, m is positive, and c and m are relatively prime, and $ac \equiv bc \pmod{m}$, then $a \equiv b \pmod{m}$.

8. If a, b, k, and m are integers with k and m positive and $a \equiv b \pmod{m}$, then $a^k \equiv b^k \pmod{m}$.

9. Suppose a, b, and m are integers with $a \equiv b \pmod{m}$. If c is an integer, it does not necessarily follow that $c^a \equiv c^b \pmod{m}$.

10. If $f(x_1, \ldots, x_n)$ is a polynomial with integer coefficients and $a_1, \ldots, a_n, b_1, \ldots, b_n$ are integers with $a_i \equiv b_i \pmod{m}$ for all i, then $f(a_1, \ldots, a_n) \equiv f(b_1, \ldots, b_n) \pmod{m}$.

11. If a, b, and m_i are integers with m_i positive and $a \equiv b \pmod{m_i}$ for $i = 1, 2, \ldots, k$, then $a \equiv b \pmod{\operatorname{lcm}(m_1, m_2, \ldots, m_k)}$.

12. If a and b are integers, m_i $(i = 1, 2, \ldots, k)$ are pairwise relatively prime positive integers, and $a \equiv b \pmod{m_i}$ for $i = 1, 2, \ldots, k$, then $a \equiv b \pmod{m_1 m_2 \ldots m_k}$.

13. The congruence class $[a]_m$ is the set of integers $\{a, a \pm m, a \pm 2m, \ldots\}$. If $a \equiv b \pmod{m}$, then $[a]_m = [b]_m$. The congruence classes modulo m are the equivalence classes of the congruence modulo m equivalence relation. (See §5.2.1.)

14. Addition, subtraction, and multiplication of congruence classes modulo m, where m is a positive integer, are defined by $[a]_m + [b]_m = [a+b]_m$, $[a]_m - [b]_m = [a-b]_m$, and $[a]_m[b]_m = [ab]_m$. Each of these operations is well defined, in the sense that using representatives of the congruence classes other than a and b does not change the resulting congruence class.

15. If m is a positive integer, then $(\mathcal{Z}_n, +)$, where $+$ is the operation of addition of congruence classes defined in Fact 14 and in §5.2.1, is an abelian group. The identity element in this group is $[0]_m$ and the inverse of $[a]_m$ is $[-a]_m = [m-a]_m$.

16. If m is a positive integer greater than 1 and a is relatively prime to m, then a has an inverse modulo m.

17. An inverse of a modulo m, where m is a positive integer and $\gcd(a,m) = 1$, may be found by using the extended Euclidean algorithm to find integers x and y such that $ax + my = 1$, which implies that x is an inverse of a modulo m.

18. If m is a positive integer, then $(\mathcal{Z}_m^\star, \cdot)$, where $\cdot$ is the multiplication operation on congruence classes, is an abelian group. (See §5.2.1.) The identity element of this group is $[1]_m$ and the inverse of the class $[a]_m$ is the class $[\overline{a}]_m$, where $\overline{a}$ is an inverse of a modulo m.

19. If a_i $(i = 1, \ldots, m)$ is a complete residue system modulo m, where m is a positive integer, and r and s are integers with $\gcd(m,r) = 1$, then $ra_i + s$ is a complete system of residues modulo m.

20. If a and b are integers and m is a positive integer with $0 \le a < m$ and $0 \le b < m$, then $(a+b)$ **mod** $m = a+b$ if $a+b < m$, and $(a+b)$ **mod** $m = a+b-m$ if $a+b \ge m$.

21. Computing the least positive residue modulo m of powers of integers is important in cryptology (see Chapter 15). An efficient algorithm for computing b^n **mod** m where n is a positive integer with binary expansion $n = (a_{k-1} \ldots a_1 a_0)_2$ is to find the least positive residues of $b, b^2, b^4, \ldots, b^{2^{k-1}}$ modulo m by successively squaring and reducing modulo m, multiplying together the least positive residues modulo m of b^{2^j} for those j with $a_j = 1$, reducing modulo m after each multiplication.

22. *Wilson's theorem*: If p is prime, then $(p-1)! \equiv -1 \pmod{p}$.

23. If n is a positive integer greater than 1 such that $(n-1)! \equiv -1 \pmod{n}$ then n is prime.

24. *Fermat's little theorem*: If p is a prime and a is an integer not divisible by p then $a^{p-1} \equiv 1 \pmod{p}$.

25. *Euler's theorem*: If m is a positive integer and a is an integer relatively prime to m, then $a^{\phi(m)} \equiv 1 \pmod{m}$, where $\phi(m)$ is the number of positive integers not exceeding m that are relatively prime to m.

26. If a is an integer and p is a prime that does not divide a, then from Fermat's little theorem it follows that a^{p-2} is an inverse of a modulo p.

27. If a and m are relatively prime integers with $m > 1$, then $a^{\phi(m)-1}$ is an inverse of a modulo m. This follows directly from Euler's theorem.

28. *Linear congruential method*: One of the most commonly used methods for generating pseudo-random numbers is the *linear congruential method.* It starts with integers m, a, c, and x_0 where $2 \le a < m$, $0 \le c < m$, and $0 \le x_0 \le m$. The sequence of pseudo-random numbers is defined recursively by

$$x_{n+1} = (ax_n + c) \, \mathbf{mod} \, m, \quad n = 0, 1, 2, 3, \ldots.$$

Here m is the *modulus*, a is the *multiplier*, c is the *increment*, and x_0 is the *seed* of the generator.

29. Big-oh estimates for the number of bit operations required to do modular addition, modular subtraction, modular multiplication, modular inversion, and modular exponentiation are summarized in the following table.

name	*operation*	*number of bit operations*
modular addition	$(a+b)$ **mod** m	$O(\log m)$
modular subtraction	$(a-b)$ **mod** m	$O(\log m)$
modular multiplication	$(a \cdot b)$ **mod** m	$O(\log^2 m)$
modular inversion	(a^{-1}) **mod** m	$O(\log^2 m)$
modular exponentiation	a^k **mod** m, $k < m$	$O(\log^3 m)$

Examples:

1. $23 \equiv 5 \pmod 9$, $-17 \equiv 13 \pmod{15}$, and $99 \equiv 0 \pmod{11}$, but $11 \not\equiv 3 \pmod 5$, $-3 \not\equiv 8 \pmod 6$, and $44 \not\equiv 0 \pmod 7$.

2. To find an inverse of 53 modulo 77, use the extended Euclidean algorithm to obtain $16 \cdot 53 - 11 \cdot 77 = 1$ (see Example 1 of §4.2.2). This implies that 16 is an inverse of 53 modulo 77.

3. Since 11 is prime, by Wilson's theorem it follows that $10! \equiv -1 \pmod{11}$.

4. $5! \equiv 0 \pmod 6$, which provides an impractical verification that 6 is not prime.

5. To find the least positive residue of 3^{201} modulo 11, note that by Fermat's little theorem $3^{10} \equiv 1 \pmod{11}$. Hence $3^{201} = (3^{10})^{20} \cdot 3 \equiv 3 \pmod{11}$.

6. *Zeller's congruence*: A congruence can be used to determine the day of the week of any date in the Gregorian calendar, the calendar used in most of the world. Let w represent the day of the week, with $w = 0, 1, 2, 3, 4, 5, 6$ for Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, respectively. Let k represent the day of the month. Let m represent the month with $m = 11, 12, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10$ for January, February, March, April, May, June, July, August, September, October, November, December, respectively. Let N represent the previous year if the month is January or February or the current year otherwise, with C the century of N and Y the particular year of the century of N so that $N = 100Y + C$. Then the day of the week can be found using the congruence

$$w \equiv k + \lfloor 2.6m - 0.2 \rfloor - 2C + Y + \left\lfloor \tfrac{Y}{4} \right\rfloor + \left\lfloor \tfrac{C}{4} \right\rfloor \pmod 7.$$

7. January 1, 1900 was a Monday. This follows by Zeller's congruence with $C = 18$, $Y = 99$, $m = 11$, and $k = 1$, noting that to apply this congruence January is considered the eleventh month of the preceding year.

4.3.2 LINEAR AND POLYNOMIAL CONGRUENCES

Definitions:

A ***linear congruence in one variable*** is a congruence of the form $ax \equiv b \pmod m$, where a, b, and m are integers, m is positive, and x is an unknown.

If f is a polynomial with integer coefficients, an integer r is a ***solution*** of the congruence $f(x) \equiv 0 \pmod m$, or a ***root*** of $f(x)$ modulo m, if $f(r) \equiv 0 \pmod m$.

Facts:

1. If a, b, and m are integers, m is positive, and $\gcd(a, m) = d$, then the congruence $ax \equiv b \pmod{m}$ has exactly d incongruent solutions modulo m if $d|b$, and no solutions if $d \not| \, b$.

2. If a, b, and m are integers, m is positive, and $\gcd(a, m) = 1$, then the solutions of $ax \equiv b \,(\text{mod } m)$ are all integers x with $x \equiv \overline{a}b \,(\text{mod } m)$.

3. If a and b are positive integers and p is a prime that does not divide a, then the solutions of $ax \equiv b \pmod{p}$ are the integers x with $x \equiv a^{p-2}b \pmod{p}$.

4. *Thue's lemma*: If p is a prime and a is an integer not divisible by p, then the congruence $ax \equiv y \,(\text{mod } p)$ has a solution x_0, y_0 with $0 < |x_0| < \sqrt{p}$, $0 < |y_0| < \sqrt{p}$.

5. *Chinese remainder theorem*: If m_i, $i = 1, 2, \ldots, r$, are pairwise relatively prime positive integers, then the system of simultaneous congruences $x \equiv a_i \,(\text{mod } m_i)$, $i = 1, 2, \ldots, r$, has a unique solution modulo $M = m_1 m_2 \ldots m_r$ which is given by $x \equiv a_1M_1y_1 + a_2M_2y_2 + \cdots + a_rM_ry_r$ where $M_k = \frac{M}{m_k}$ and y_k is an inverse of M_k modulo m_k, $k = 1, 2, \ldots, r$.

6. Problems involving the solution of a system of simultaneous congruences arose in the writing of ancient mathematicians, including the Chinese mathematician Sun-Tsu, and in other works by Indian and Greek mathematicians. (See [Di71] for details.)

7. The system of simultaneous congruences $x \equiv a_i \,(\text{mod}\, m_i)$, $i = 1, 2, \ldots, r$, has a solution if and only if $\gcd(m_i, m_j)$ divides $a_i - a_j$ for all pairs of integers (i, j) with $1 \leq i < j \leq r$. If a solution exists, it is unique modulo $\text{lcm}(m_1, m_2, \ldots, m_r)$.

8. If a, b, c, d, e, f, and m are integers with m positive such that $\gcd(ad - bc, m) = 1$, then the system of congruences $ax + by \equiv e \pmod{m}$, $cx + dy \equiv f \pmod{m}$ has a unique solution given by $x \equiv g(de - bf) \pmod{m}$, $y \equiv g(af - ce) \pmod{m}$ where g is an inverse of $ad - bc$ modulo m.

9. *Lagrange's theorem*: If p is prime, then the polynomial $f(x) = a_nx^n + \cdots + a_1x + a_0$ with $a_n \not\equiv 0 \,(\text{mod } p)$ has at most n roots modulo p.

10. If $f(x) = a_nx^n + \cdots + a_1x + a_0$, where a_i $(i = 1, \ldots, n)$ is an integer and p is prime, has more than n roots modulo p, then p divides a_i for all $i = 1, \ldots, n$.

11. If $m_1, m_2, \ldots, m_r$ are pairwise relatively prime positive integers with product $m = m_1m_2 \ldots m_r$, and f is a polynomial with integer coefficients, then $f(x)$ has a root modulo m if and only if $f(x)$ has a root modulo m_i, for all $i = 1, 2, \ldots, r$. Furthermore, if $f(x)$ has n_i incongruent roots modulo m_i and n incongruent roots modulo m, then $n = n_1n_2 \ldots n_r$.

12. If p is prime, k is a positive integer, and s is a root of $f(x)$ modulo p^k, then

- if $p \not| f'(s)$, then there is a unique root t of $f(x)$ modulo p^{k+1} with $t \equiv s \pmod{p^k}$, namely $t = s + p^ku$ where u is the unique solution of $f'(s)u \equiv -f(s)/p^k \,(\text{mod}\, p)$;
- if $p|f'(s)$ and $p^{k+1}|f(s)$, then there are exactly p incongruent roots of $f(x)$ modulo p^{k+1} congruent to s modulo p, given by $s + p^ki$, $i = 0, 1, \ldots, p - 1$;
- if $p|f'(s)$ and $p^{k+1} \not| \, f(s)$, then there are no roots of $f(x)$ modulo p^{k+1} that are congruent to s modulo p^k.

13. *Finding roots of a polynomial modulo m, where m is a positive integer*: First find roots of the polynomial modulo p^r for each prime power in the prime-power factorization of m (Fact 14) and then use the Chinese remainder theorem (Fact 5) to find solutions modulo m.

14. Finding solutions modulo p^r reduces to first finding solutions modulo p. In particular, if there are no roots of $f(x)$ modulo p, there are no roots of $f(x)$ modulo p^r. If $f(x)$

has roots modulo p, choose one, say r with $0 \leq r < p$. By Fact 12, corresponding to r there are 0, 1, or p roots of $f(x)$ modulo p^2.

Examples:

1. There are three incongruent solutions of $6x \equiv 9 \pmod{15}$ since $\gcd(6,15) = 3$ and $3|9$. The solutions are those integers x with $x \equiv 4, 9,$ or $14 \pmod{15}$.

2. The linear congruence $2x \equiv 7 \pmod 6$ has no solutions since $\gcd(2,6) = 2$ and $2 \nmid 7$.

3. The solutions of the linear congruence $3x \equiv 5 \pmod{11}$ are those integers x with $x \equiv \overline{3} \cdot 5 \equiv 4 \cdot 5 \equiv 9 \pmod{11}$.

4. It follows from the Chinese remainder theorem (Fact 5) that the solutions of the systems of simultaneous congruences $x \equiv 1 \pmod 3$, $x \equiv 2 \pmod 4$, and $x \equiv 3 \pmod 5$ are all integers x with $x \equiv 1 \cdot 20 \cdot 2 + 2 \cdot 15 \cdot 3 + 3 \cdot 12 \cdot 3 \equiv 58 \pmod{60}$.

5. The simultaneous congruences $x \equiv 4 \pmod 9$ and $x \equiv 7 \pmod{15}$ can be solved by noting that the first congruence implies that $x - 4 = 9t$ for some integer t, so that $x = 9t + 4$. Inserting this expression for x into the second congruence gives $9t + 4 \equiv 7 \pmod{15}$. This implies that $3t \equiv 1 \pmod 5$, so that $t \equiv 2 \pmod 5$ and $t = 5u + 2$ for some integer u. Hence $x = 45u + 22$ for some integer u. The solutions of the two simultaneous congruences are those integers x with $x \equiv 22 \pmod{45}$.

4.4 PRIME NUMBERS

One of the most powerful tools in number theory is the fact that each composite integer can be decomposed into a product of primes. Primes may be thought of as the building blocks of the integers in the sense that they can be decomposed only in trivial ways, for example, $3 = 1 \times 3$. Prime numbers, once of only theoretical interest, now are important in many applications, especially in the area of cryptography where large primes play a crucial role in the area of public key cryptosystems (see Chapter 15). From ancient to modern times, mathematicians have devoted long hours to the study of primes and their properties. Even so, many questions about primes have only partially been answered or remain complete mysteries, including questions that ask whether there are infinitely many primes of certain forms. There have been many recent discoveries concerning prime numbers, such as the discovery of new Mersenne primes or the proof that infinitely often there are pairs of primes at most a bounded distance apart.. The current state of knowledge on some of these questions and the latest discoveries are described in this section.

Additional information about primes can be found in [CrPo05] and [Ri96], as well as the *Prime Pages* website `http://www.utm.edu/research/primes/`.

4.4.1 BASIC CONCEPTS

Definitions:

A ***prime*** is a natural number greater than 1 that is exactly divisible only by 1 and itself.

A ***composite*** is a natural number greater than 1 that is not a prime. That is, a composite may be factored into the product of two natural numbers both smaller than itself.

Facts:

1. The number 1 is not considered to be prime.

2. The following table lists the primes less than 10,000. The prime number p_{10n+k} is found by looking at the row beginning with n.. and at the column beginning with ..k.

	..0	..1	..2	..3	..4	..5	..6	..7	..8	..9

3. *Fundamental theorem of arithmetic*: Every natural number greater than 1 is either prime or can be written as a product of prime factors in a unique way, up to the order of the prime factors. That is, every composite n can be expressed uniquely as $n = p_1 p_2 \dots p_k$, where $p_1 \leq p_2 \leq \cdots \leq p_k$ are primes. This is sometimes also known as the *unique factorization theorem.*

4. The unique factorization of a positive integer n formed by grouping together equal prime factors produces the unique *prime-power factorization* $n = p_1^{a_1} p_2^{a_2} \dots p_k^{a_k}$.

5. The following table lists the prime-power factorization of all positive integers below 2,500. Numbers appearing in boldface are prime.

	0	1	2	3	4	5	6	7	8	9

Examples:

1. $6 = 2 \times 3$.

2. $245 = 5 \times 7^2$.

3. $10! = 2^8 \times 3^4 \times 5^2 \times 7$.

4. $68{,}718{,}821{,}377 = (2^{17} - 1) \cdot (2^{19} - 1)$ (both factors are Mersenne primes; see §4.4.3).

5. The largest prime known is $2^{74{,}207{,}281} - 1$, which has 22,338,618 decimal digits. It is a Mersenne prime (see Table 2).

4.4.2 COUNTING PRIMES

Definitions:

The value of the ***prime counting function*** $\pi(x)$ at x, where x is a positive real number, equals the number of primes less than or equal to x.

The ***li function*** is defined by $\text{li}(x) = \int_0^x \frac{dt}{\ln t}$, for $x \geq 2$. (The principal value is taken for the integral at the singularity $t = 1$.)

Twin primes are primes that differ by exactly 2.

Facts:

1. Euclid (*ca.* 300 BCE) proved that there are infinitely many primes. He observed that the product of a finite list of primes, plus one, must be divisible by a prime not on that list.

2. Leonhard Euler (1707–1783) showed that the sum of the reciprocals of the primes up to n tends toward infinity as n tends toward infinity, which also implies that there are infinitely many primes. (There are many other proofs as well.)

3. There is no useful, exact formula known which will produce the nth prime, given n. It is relatively easy to construct a useless (that is, impractical) one. For example, let $\alpha = \sum_{n=1}^{\infty} p_n / 2^{2^n}$, where p_n is the nth prime. Then the nth prime is $\lfloor 2^{2^n}\alpha \rfloor - 2^{2^{n-1}} \lfloor 2^{2^{n-1}}\alpha \rfloor$, where $\lfloor x \rfloor$ is the greatest integer less than or equal to x.

4. If $f(x)$ is a polynomial with integer coefficients that is not constant, then there are infinitely many integers n for which $|f(n)|$ is not prime.

5. There are polynomials with integer coefficients with the property that the set of positive values taken by each of these polynomials as the variables range over the set of nonnegative integers is the set of prime numbers. The existence of such polynomials has essentially no practical value for constructing primes. For example, there are polynomials in 26 variables of degree 25, in 42 variables of degree 5, and in 12 variables of degree 13,697 that have this property. (See [Ri96].)

6. $\frac{p_n}{n \log n} \to 1$ as $n \to \infty$. (This follows from the prime number theorem, Fact 10.)

7. An inexact and rough formula for the nth prime is $n \log n$.

8. $p_n > n \log n$ for all n. (J. B. Rosser)

9. *The sieve of Eratosthenes*: Eratosthenes (3rd century BCE) developed a method (Algorithm 1) for listing all prime numbers less than a fixed bound N. This method starts from the prime 2 and successively eliminates all of its multiple from the list. It continues through the list and successively eliminates multiples of the next (prime) value. Only trial values up to the square root of N need to be tested.

Algorithm 1: **Sieve of Eratosthenes.**

```
make a list of the numbers from 2 to $N$
$i := 1$
while $i \leq \sqrt{N}$
    $i := i + 1$
    if $i$ is not already crossed out then cross out all proper multiples of $i$ that
        are less than or equal to $N$
{The numbers not crossed out then comprise the primes up to $N$}
```

10. *Prime number theorem*: $\pi(x)$, when divided by $\frac{x}{\log x}$, tends to 1 as x tends to infinity. That is, $\pi(x)$ is asymptotic to $\frac{x}{\log x}$ as $x \to \infty$.

11. The prime number theorem was first conjectured by Carl Friedrich Gauss (1777–1855) in 1792, and was first proved in 1896 independently by Charles de la Vallée Poussin (1866–1962) and Jacques Hadamard (1865–1963). They proved it in the stronger form $|\pi(x) - \mathrm{li}(x)| < c_1 x e^{-c_2\sqrt{\log x}}$, where c_1 and c_2 are positive constants. Their proofs used functions of a complex variable. The first elementary proofs (not using complex variables) of the prime number theorem were supplied in 1949 by Paul Erdős (1913–1996) and Atle Selberg (1917–2007).

12. Integration by parts shows that $\mathrm{li}(x)$ is asymptotic to $\frac{x}{\log x}$ as $x \to \infty$.

13. $|\pi(x) - \mathrm{li}(x)| < c_3 x e^{-c_4 (\log x)^{3/5} (\log\log x)^{-1/5}}$ for certain positive constants c_3 and c_4. (I. M. Vinogradov and Nikolai Korobov, 1958.)

14. If the Riemann hypothesis (see Open Problem 1) is true, $|\pi(x) - \mathrm{li}(x)|$ is bounded by $\sqrt{x}\log x$ for all $x \geq 2$. Note that conversely, if $|\pi(x) - \mathrm{li}(x)| < \sqrt{x}\log x$ for all $x \geq 2$, then the Riemann hypothesis is true.

15. J. E. Littlewood (1885–1977) showed that $\pi(x) - \mathrm{li}(x)$ changes sign infinitely often. However, no explicit number x with $\pi(x) - \mathrm{li}(x) > 0$ is known. Carter Bays and Richard H. Hudson have shown that such a number x exists below $1.4 \cdot 10^{316}$. It is also known (D. Platt and T. Trudgian) that $\pi(x) < \mathrm{li}(x)$ for all $x < 1.39 \cdot 10^{17}$.

16. The largest exactly computed value of $\pi(x)$ is $\pi(10^{26})$. This value, computed by D. B. Staple in 2015, is about $1.56 \cdot 10^{11}$ below $\mathrm{li}(10^{26})$. (See the following table.)

n	$\pi(10^n)$	$\approx \pi(10^n) - \text{li}(10^n)$
1	4	−2
2	25	−5

17. *Dirichlet's theorem on primes in arithmetic progressions*: Given coprime integers a, b with b positive, there are infinitely many primes $p \equiv a \pmod{b}$. G. L. Dirichlet proved this in 1837.

18. The number of primes p less than x such that $p \equiv a \pmod{b}$ is asymptotic to $\frac{1}{\phi(b)}\pi(x)$ as $x \to \infty$, if a and b are coprime and b is positive. (Here ϕ is the Euler phi-function; see §4.6.2.)

Open Problems:

1. *Riemann hypothesis*: The *Riemann hypothesis* (*RH*), posed in 1859 by Bernhard Riemann (1826–1866), is a conjecture about the location of zeros of the *Riemann zeta function*, the function of the complex variable s defined by the series $\zeta(s) = \sum_{n=1}^{\infty} n^{-s}$ when the real part of s is > 1, and defined by the formula

$$\zeta(s) = \tfrac{s}{s-1} - s\int_1^{\infty}(x - \lfloor x \rfloor)x^{-s-1}\,dx$$

in the larger region when the real part of s is > 0, except for the single point $s = 1$, where it remains undefined. The Riemann hypothesis asserts that all of the solutions to $\zeta(s) = 0$ in this larger region lie on the vertical line in the complex number plane with real part $\frac{1}{2}$. Its proof would imply a better error estimate for the prime number theorem. While believed to be true, it has not been proved. (See Fact 14.)

2. *Extended Riemann hypothesis*: There is a generalized form of the Riemann hypothesis known as the *extended Riemann hypothesis* (*ERH*) or the *generalized Riemann hypothesis* (*GRH*), which also has important consequences in number theory. (For example, see §4.4.4.)

3. *Hypothesis H*: The *hypothesis H* of Andrzej Schinzel and Wacław Sierpiński (1882–1969) asserts that for every collection of irreducible nonconstant polynomials $f_1(x), \ldots, f_k(x)$ with integral coefficients and positive leading coefficients, if there is no fixed integer greater than 1 dividing the product $f_1(m) \ldots f_k(m)$ for all integers m, then there are infinitely many integers m such that each of the numbers $f_1(m), \ldots, f_k(m)$ is prime. The case when each of the polynomials is linear was previously conjectured by L. E. Dickson, and is known as the *prime k-tuples conjecture*. The only case of Hypothesis H that has been proved is the case of a single linear polynomial; this is Dirichlet's theorem (Fact 17). The case of the two linear polynomials x and $x + 2$ corresponds to the twin prime conjecture (Open Problem 4). Among the many consequences of Hypothesis H is the assertion that there are infinitely many primes of the form $m^2 + 1$.

4. *Twin primes*: It has been conjectured that there are infinitely many twin primes, that is, pairs of primes that differ by 2.

Let d_n denote the difference between the $(n+1)$st prime and the nth prime. The sequence d_n is unbounded. The prime number theorem implies that on average d_n is about $\log n$. The twin prime conjecture asks whether d_n is 2 infinitely often. Although no proof of the infinitude of twin primes has been found, some results have recently been proved about the infinitude of primes that differ by a particular positive integer greater than two. In 2013 Yitang Zhang surprised the mathematical community when he proved that there is an integer N with $N < 70{,}000{,}000$ such that infinitely many pairs of primes differ by N. In later work by the Polymath Project, a collaborative effort to further mathematical research, Zhang's bound was reduced to 246. (Under the assumption that certain hypotheses hold, this bound can be reduced to as little as 6.) The hope is that this work may eventually lead to a proof of the twin prime conjecture.

5. It is conjectured that d_n can be as big as $\log^2 n$ infinitely often, but not much bigger. Roger Baker and Glyn Harman have recently shown that $d_n < n^{.535}$ for all large numbers n. For the other direction, in 2014 Ford, Green, Konyagin, and Tao showed that $d_n > c \log n (\log\log n)(\log\log\log\log n)/(\log\log\log n)$ infinitely often. Several improvements have been made on the constant c, but this ungainly expression has stubbornly resisted improvement.

6. Christian Goldbach (1690–1764) conjectured that every integer greater than 5 is the sum of three primes.

7. *Goldbach's conjecture*: Christian Goldbach (1690–1764) conjectured that every even integer greater than 2 is a sum of two primes.

- In 2013 the Goldbach conjecture was verified up to $4 \cdot 10^{18}$ by Olveira e Silva, Herzog, and Pardi.
- Goldbach also conjectured that all odd integers greater than 7 are the sum of three primes. This was proved by Harald Helfgott in 2013 and involved a verification of this conjecture for all odd integers n with $7 \le n < 10^{27}$ done by David Platt.
- In 1966 J. R. Chen proved that every sufficiently large even number is either the sum of two primes or the sum of a prime and a number that is the product of two primes.

8. In 2004 B. Green and T. Tao proved the conjecture made in 1770 that the sequence of prime numbers contains arbitrarily long arithmetic progressions.

Examples:

1. A method for showing that there are infinitely many primes is to note that the integer $n!+1$ must have a prime factor greater than n, so there is no largest prime. Note that $n!+1$ is prime for $n = 1, 2, 3, 11, 27, 37, 41, 73, 77, 116, 154, 320, 340, 399$, and 427, but is composite for all positive integers less than 427 not listed.

2. For p a prime, let $Q(p)$ equal one more than the product of the primes not exceeding p. For example $Q(5) = 2\cdot3\cdot5+1 = 31$. Then $Q(p)$ is prime for $p = 2, 3, 5, 7, 11, 31, 379, 1019, 1021, 2657, 3229, 4547, 4787, 11549, 13649$; it is composite for all $p < 11213$ not in this list. For example, $Q(13) = 2\cdot3\cdot5\cdot7\cdot11\cdot13+1$ is composite.

3. There are six primes not exceeding 16, namely $2, 3, 5, 7, 11, 13$. Hence $\pi(16) = 6$.

4. The expression n^2+1 is prime for $n = 1, 2, 4, 6, 10, \ldots$, but it is unknown whether there are infinitely many primes of this form when n is an integer. (See Open Problem 3.)

5. The polynomial $f(n) = n^2 + n + 41$ takes on prime values for $n = 0, 1, 2, \ldots, 39$, but $f(40) = 1681 = 41^2$.

6. Applying Dirichlet's theorem with $a = 123$ and $b = 1{,}000$, there are infinitely many primes that end in the digits 123. The first such prime is 1,123.

7. The pairs 17, 19 and 191, 193 are twin primes. As of the publication of this book, the largest known twin primes, $2{,}996{,}863{,}034{,}895\cdot 2^{1{,}290{,}000}\pm 1$, have 388,342 decimal digits. They were found in 2016 by the Twin Prime Search, a dedicated effort for finding twin primes begun in 2006, in conjunction with PrimeGrid, a distributed computing project for finding world record prime numbers of various types:

- `https://www.primegrid.com`

4.4.3 NUMBERS OF SPECIAL FORM

Numbers of the form $b^n \pm 1$, for b a small number, are often easier to factor or test for primality than other numbers of the same size. They also have a colorful history.

Definitions:

A ***Cunningham number*** is a number of the form $b^n \pm 1$, where b and n are natural numbers, and b is "small" — 2, 3, 5, 6, 7, 10, 11, or 12. They are named after Allan Cunningham, who, along with H. J. Woodall, published in 1925 a table of factorizations of many of these numbers.

A ***Fermat number*** F_m is a Cunningham number of the form $2^{2^m}+1$. (See Table 1.)

A ***Fermat prime*** is a Fermat number that is prime.

A ***Mersenne number*** M_n is a Cunningham number of the form $2^n - 1$.

A ***Mersenne prime*** is a Mersenne number that is prime. (See Table 2.)

The ***cyclotomic polynomials*** $\Phi_k(x)$ are defined recursively by the equation $x^n - 1 = \prod_{d|n} \Phi_d(x)$.

A ***perfect number*** is a positive integer that is equal to the sum of all its proper divisors.

Facts:

1. If M_n is prime, then n is prime, but the converse is not true.

2. If $b > 2$ or n is composite, then a nontrivial factorization of $b^n - 1$ is given by $b^n - 1 = \prod_{d|n} \Phi_d(b)$, though the factors $\Phi_d(b)$ are not necessarily primes.

3. The number $b^n + 1$ can be factored as the product of $\Phi_d(b)$, where d runs over the divisors of $2n$ that are not divisors of n. When n is not a power of 2 and $b \geq 2$, this factorization is nontrivial.

4. Some numbers of the form $b^n \pm 1$ also have so-called *Aurifeuillian factorizations*, named after A. Aurifeuille. For more details, see [BrEtal88].

5. The only primes of the form $b^n - 1$ (with $n > 1$) are Mersenne primes.

6. The only primes of the form $2^n + 1$ are Fermat primes.

7. Fermat numbers are named after Pierre de Fermat (1601–1695), who observed that F_0, F_1, F_2, F_3, and F_4 are prime and stated (incorrectly) that all such numbers are prime. Euler proved this was false, by showing that $F_5 = 2^{32} + 1 = 641 \cdot 6{,}700{,}417$.

8. F_4 is the largest known Fermat prime. It is conjectured that all larger Fermat numbers are composite.

9. The smallest Fermat number that has not yet been completely factored is $F_{12} = 2^{2^{12}} + 1$, which has a 1187-digit composite factor.

10. As of 2016, we know that F_m is composite for all m with $5 \leq m \leq 32$. In all, we know 288 values of m for which F_m is composite. The largest such F_m, with $m = 3{,}329{,}780$, was established as composite in 2014 when it was shown to be divisible by $193 \cdot 2^{3{,}329{,}782} + 1$.

11. At least one prime factor is known for the F_m in Fact 10 except for F_{20} and F_{24}. The complete factorization of F_m is only known for $0 \leq m \leq 11$.

12. Table 1 provides known factorizations of F_m for $0 \leq m \leq 24$. Here p_k indicates a k-digit prime, and c_k indicates a k-digit composite. All other numbers appearing in the right column have been proved prime.

13. For up-to-date information about the factorization of Fermat numbers, see

- `http://www.maths.dur.ac.uk/users/dzmitry.badziahin/Fermat%20factoring%20status.html`

14. *Pepin's criterion*: For $m \geq 1$, F_m is prime if and only if $3^{(F_m-1)/2} \equiv -1 \pmod{F_m}$.

15. For $m \geq 2$, every factor of F_m is of the form $2^{m+2}k + 1$.

16. Mersenne numbers are named after Marin Mersenne (1588–1648), who made a list of what he thought were all the Mersenne primes M_p with $p \leq 257$. (The status of M_p for the primes up to 23 was known prior to Mersenne.) His list consisted of the primes $p = 2, 3, 5, 7, 13, 17, 19, 31, 67, 127$, and 257. However, it was later shown that M_{67} and M_{257} are composite, while M_{61}, M_{89}, and M_{107}, missing from the list, are prime.

17. It is not known whether there are infinitely many Mersenne primes, nor whether infinitely many Mersenne numbers with a prime exponent are composite, though it is conjectured that both are true.

18. Euclid showed that the product of a Mersenne prime $2^p - 1$ with 2^{p-1} is perfect. Euler showed that every even perfect number is of this form.

Table 1: Fermat numbers.

19. The *Lucas-Lehmer test* can be used to determine whether a given Mersenne number is prime or composite. (See Algorithm 2.)

Algorithm 2: **Lucas-Lehmer test.**

```
$p :=$ an odd prime; $u := 4$; $i := 0$
while $i \leq p - 2$
  $i := i + 1$
  $u := u^2 - 2$ mod $2^p - 1$
{If $u = 0$ then $2^p - 1$ is prime, else $2^p - 1$ is composite}
```

20. Table 2 lists all known Mersenne primes. An asterisk indicates that a discovery was made as part of the GIMPS program (see Fact 21). As of 2016, the largest known Mersenne prime is $2^{74,207,281} - 1$. As of 2016 we know that there are no additional Mersenne primes less than the 44th prime listed, but there may be one or more Mersenne primes between the 44th Mersenne prime and the largest prime on this list. When a new Mersenne prime is found by computer, there may be other numbers of the form M_p less than this prime not yet checked for primality. It can take months, or even years, to do this checking. A new Mersenne prime may even be found this way, as was the case for the 29th.

Table 2: Mersenne primes.

21. George Woltman launched the Great Internet Mersenne Prime Search (GIMPS) in 1996. GIMPS provides free software for PCs. GIMPS has played a role in discovering the last 15 Mersenne primes. Thousands of people participate in GIMPS over PrimeNet, a virtual supercomputer of distributed PCs, together running more than 250 Teraflops in the quest for Mersenne primes. Consult the GIMPS website at `http://www.mersenne.org` for more information about this quest and how to join it.

22. As of 2016, the two smallest composite Mersenne numbers not completely factored were $2^{671} - 1$ and $2^{683} - 1$.

23. It is not known whether any odd perfect numbers exist. Odd perfect numbers, if they exist, must satisfy many different conditions that have been proved over the last 130 years. As of 2016, we know that there are none below 10^{300}, a result of R. P. Brent, G. L. Cohen, and H. J. J. te Riele in 1991. Among other known conditions are that an odd perfect number must have at least 75 prime factors (proved by K. G. Hare in 2005) and at least nine distinct prime factors (proved by P. P. Neilsen in 2006).

24. The best reference for the history of the factorization of Cunningham numbers is [BrEtal88].

25. The current version of the Cunningham table, maintained by Sam Wagstaff, can be found at `https://homes.cerias.purdue.edu/~ssw/cun/index.html`.

Examples:

1. The Mersenne number $M_{11} = 2^{11} - 1$ is not prime since $M_{11} = 23 \cdot 89$.

2. To factor $342 = 7^3 - 1$ note that $7^3 - 1 = (7-1) \cdot (7^2 + 7 + 1) = 6 \cdot 57$.

3. To factor $3^7 + 1$ note that $3^7 + 1 = \Phi_2(3)\Phi_{14}(3) = 4 \cdot 547$.

4. An example of an Aurifeuillian factorization is given by $2^{4k-2} + 1 = (2^{2k-1} - 2^k + 1) \cdot (2^{2k-1} + 2^k + 1)$.

5. $\Phi_1(x) = x - 1$ and $x^3 - 1 = \Phi_1(x)\Phi_3(x)$, so $\Phi_3(x) = (x^3 - 1)/\Phi_1(x) = x^2 + x + 1$.

4.4.4 PSEUDOPRIMES AND PRIMALITY TESTING

Finding efficient ways to determine whether a positive integer is prime has fascinated mathematicians from ancient to modern times. (See [CrPo05] and [Po10].) Many of the most suggested approaches begin by studying the congruence in Fermat's little theorem when the modulus is not prime. This leads to the notions of a pseudoprime and to probabilistic primality tests. These tests are applied to produce large primes that are used in public key cryptography (see Chapter 15).

Definitions:

A ***pseudoprime to the base b*** is a composite number n such that $b^n \equiv b \pmod{n}$.

A ***pseudoprime*** is a pseudoprime to the base 2.

A ***Carmichael number*** is a pseudoprime to all bases.

A ***strong pseudoprime to the base b*** is an odd composite number $n = 2^s d + 1$, with d odd, and either $b^d \equiv 1 \pmod{n}$ or $b^{2^r d} \equiv -1 \pmod{n}$ for some integer r, $0 \le r < s$.

A ***witness*** for an odd composite number n is a base b, with $1 < b < n$, to which n is not a strong pseudoprime. Thus, b is a "witness" to n being composite.

A ***primality proof*** is an irrefutable verification that an integer is prime.

Facts:

1. By Fermat's little theorem (§4.3.1), $b^{p-1} \equiv 1 \pmod{p}$ for all primes p and all integers b that are not multiples of p. Thus, the only numbers $n > 1$ with $b^{n-1} \equiv 1 \pmod{n}$ are primes and pseudoprimes to the base b (which are coprime to b). Similarly, the numbers n which satisfy the strong pseudoprime congruence conditions are the odd primes not dividing b and the strong pseudoprimes to the base b.

2. The smallest pseudoprime is 341.

3. There are infinitely many pseudoprimes; however, Paul Erdős has proved that pseudoprimes are rare compared to primes. The same results are true for pseudoprimes to any fixed base b. (See [CrPo05] or [Ri96] for details.)

4. In 1910, Robert D. Carmichael gave the first examples of Carmichael numbers. The first 16 Carmichael numbers are

$$\begin{array}{lll}
561 = 3 \cdot 11 \cdot 17 & 1{,}105 = 5 \cdot 13 \cdot 17 & 1{,}729 = 7 \cdot 13 \cdot 19 \\
2{,}465 = 5 \cdot 17 \cdot 29 & 2{,}821 = 7 \cdot 13 \cdot 31 & 6{,}601 = 7 \cdot 23 \cdot 41 \\
8{,}911 = 7 \cdot 19 \cdot 67 & 10{,}585 = 5 \cdot 29 \cdot 73 & 15{,}841 = 7 \cdot 31 \cdot 73 \\
29{,}341 = 13 \cdot 37 \cdot 61 & 41{,}041 = 7 \cdot 11 \cdot 13 \cdot 41 & 46{,}657 = 13 \cdot 37 \cdot 97 \\
52{,}633 = 7 \cdot 73 \cdot 103 & 62{,}745 = 3 \cdot 5 \cdot 47 \cdot 89 & 63{,}973 = 7 \cdot 13 \cdot 19 \cdot 37 \\
75{,}361 = 11 \cdot 17 \cdot 31 & &
\end{array}$$

5. If n is a Carmichael number, then n is the product of at least three distinct odd primes with the property that if q is any one of these primes, then $q-1$ divides $n-1$.

6. There are a finite number of Carmichael numbers that are the product of exactly r primes with the first $r-2$ primes specified.

7. If m is a positive integer such that $6m+1$, $12m+1$, and $18m+1$ are all primes, then $(6m+1)(12m+1)(18m+1)$ is a Carmichael number.

8. In 1994, W. R. Alford (1937–2001), Andrew Granville (born 1962), and Carl Pomerance (born 1944) showed that there are infinitely many Carmichael numbers.

9. There are infinitely many numbers that are simultaneously strong pseudoprimes to each base in any given finite set. Each odd composite n, however, can be a strong pseudoprime to at most one-fourth of the bases b with $1 \le b \le n-1$.

10. Michael Rabin, building upon the notion of a strong pseudoprime introduced by J. L. Selfridge (born 1927), suggested Algorithm 3 (often referred to as the *Miller-Rabin test*).

Algorithm 3: Strong probable prime test (to a random base).

```
input: positive numbers $n$, $d$, $s$, with $d$ odd and $n = 2^s d + 1$.
$b :=$ a random integer such that $1 < b < n$
$c := b^d$ mod $n$
if $c = 1$ or $c = n - 1$, then declare $n$ a probable prime and stop
compute sequentially $c^2$ mod $n$, $c^4$ mod $n, \ldots, c^{2^{s-1}}$ mod $n$
if one of these is $n - 1$, then declare $n$ a probable prime and stop
else declare $n$ composite and stop
```

11. A "probable prime" is not necessarily a prime, but the chances are good. The probability that an odd composite is not declared composite by Algorithm 3 is at most $\frac{1}{4}$, so the probability it passes k independent iterations is at most 4^{-k}. Suppose this test is applied to random odd inputs n with the hope of finding a prime. That is, random odd numbers n (chosen between two consecutive powers of 2) are tested until one is found that passes each of k independent iterations of the test. Ronald Burthe showed in 1995 that the probability that the output of this procedure is composite is less than 4^{-k}.

12. Gary Miller proved in 1976 that if the extended Riemann hypothesis (§4.4.2) is true, then every odd composite n has a witness less than $c \log^2 n$, for some constant c. Eric Bach showed in 1985 that one may take $c = 2$. Therefore, if an odd number $n > 1$ passes the strong probable prime test for every base b less than $2 \log^2 n$, and if the extended Riemann hypothesis is true, then n is prime.

13. In practice, one can test whether numbers under $2.5 \cdot 10^{10}$ are prime by a small number of strong probable prime tests. Pomerance, Selfridge, and Wagstaff have verified (1980) that there are no numbers less than this bound that are simultaneously strong pseudoprimes to the bases 2, 3, 5, 7, and 11. Thus, any number less than $2.5 \cdot 10^{10}$ that passes those strong pseudoprime tests is a prime.

14. Gerhard Jaeschke showed in 1993 that the test described in Fact 13 works far beyond $2.5 \cdot 10^{10}$; the first number for which it fails is 2,152,302,898,747.

15. Only primes pass the strong pseudoprime tests to all the bases 2, 3, 5, 7, 11, 13, and 17 until the composite number 341,550,071,728,321 is reached.

16. While pseudoprimality tests are usually quite efficient at recognizing composites, the task of *proving* that a number is prime can be more difficult.

17. In 1983, Leonard Adleman, Carl Pomerance, and Robert Rumely developed the *APR algorithm*, which can prove that a number n is prime in time proportional to $(\log n)^{c \log \log \log n}$, where c is a positive constant. See [Co93] and [CrPo05] for details.

18. Recently, Oliver Atkin and François Morain developed an algorithm to prove primality. It is difficult to predict in advance how long it will take, but in practice it has been fast. One advantage of their algorithm is that, unlike APR, it produces a polynomial-time primality proof, though the running time to find the proof may be a bit longer. An implementation called ECPP (*elliptic curve primality proving*) is available from `http://www.lix.polytechnique.fr/Labo/Francois.Morain/Prgms/getecpp.english.html`.

19. In 1987, Carl Pomerance showed that every prime p has a primality proof whose verification involves just $c \log p$ multiplications with integers the size of p. It may be difficult, however, to find such a short primality proof.

20. In 2002, Manindra Agrawal, Neeraj Kayal, and Nitin Saxena introduced a test for determining whether a positive integer is prime that was a major breakthrough because it works in polynomial time (in terms of the number of digits of the number tested), it works for all positive integers (unlike some other tests that only work for integers of a special form), it is deterministic (that is, it always determines whether a number is prime unlike probabilistic primality tests), and its correctness does not depend on any unproven hypotheses.

21. The original AKS test determines whether a positive integer n is prime in about $\mathrm{O}(\log^{7.5} n)$ time. Improvements in the test made by Carl Pomerance and H. W. Lenstra reduce this time complexity to about $\mathrm{O}(\log^6 n)$.

22. The importance of the AKS test is more theoretical than practical at the present time. It establishes that there is a polynomial-time algorithm for determining whether a positive integer is prime. However, not even the faster versions of this test run fast enough to be used to find large primes, unlike probabilistic primality tests. (See Fact 18.)

4.5 FACTORIZATION

Determining the prime factorization of positive integers is a question that has been studied for many years (see [CrPo05] for example). Furthermore, in the past four decades, this question has become relevant for an extremely important application, the security of public key cryptosystems. The question of exactly how to decompose a composite number into the product of its prime factors is a difficult one that continues to be the subject of much research.

4.5.1 FACTORIZATION ALGORITHMS

Definition:

A ***smooth number*** is an integer all of whose prime divisors are small.

Facts:

1. The simplest algorithm for factoring an integer is *trial division*, Algorithm 1. While simple, this algorithm is useful only for numbers that have a fairly small prime factor. It can be modified so that after $j = 3$, the number j is incremented by 2, and there are other improvements of this kind.

Algorithm 1: **Trial division.**

```
input: an integer $n \geq 2$
output: $j$ (smallest prime factor of $n$) or statement that $n$ is prime
$j := 2$
```

```
while $j \leq \sqrt{n}$
  if $j|n$ then print that $j$ is a prime factor of $n$ and stop {$n$ is not prime}
  $j := j + 1$
if no factor is found then declare $n$ prime
```

2. Many factoring algorithms have been developed in the last half century. Coupled with the development of modern computers, increasing larger and larger integers can be factored. Among these factoring algorithms are the quadratic sieve (QS), Pollard $p - 1$ factorization, the number field sieve (NFS), the elliptic curve method (ECM), and the continued fraction method (CFRAC).

3. Currently, one of the fastest algorithms for numbers that are feasible to factor but do not have a small prime factor is the *quadratic sieve* (QS), Algorithm 2, invented by Carl Pomerance in 1981. (For numbers at the far range of feasibility, the *number field sieve* is faster; see Fact 10.)

```
Algorithm 2: Quadratic sieve.
  input: $n$ (an odd composite number that is not a power)
  output: $g$ (a nontrivial factor of $n$)
  find $a_1, \ldots, a_k$ such that each $a_i^2 - n$ is smooth
  find a subset of the numbers $a_i^2 - n$ whose product is a square, say $x^2$
  reduce $x$ modulo $n$
  $y :=$ the product of the $a_i$ used to form the square
  reduce $y$ modulo $n$
  {This gives a congruence $x^2 \equiv y^2 \pmod{n}$; equivalently $n|(x^2 - y^2)$}
  $g := \gcd(x - y, n)$
  if $g$ is not a nontrivial factor then find new $x$ and $y$ (if necessary, find more $a_i$)
```

4. The greatest common divisor calculation may be quickly done via the Euclidean algorithm. If $x \not\equiv \pm y \pmod{n}$, then g will be a nontrivial factor of n. (Among all solutions to the congruence $x^2 \equiv y^2 \pmod{n}$ with xy coprime to n, at least half of them lead to a nontrivial factorization of n.) Finding the a_is is at the heart of the algorithm and is accomplished using a sieve not unlike the sieve of Eratosthenes, but applied to the consecutive values of the quadratic polynomial $a^2 - n$. If a is chosen near $\sqrt{n}$, then $a^2 - n$ will be relatively small, and thus more likely to be smooth. So one sieves the polynomial $a^2 - n$, where a runs over integers near $\sqrt{n}$, for values that are smooth. When enough smooth values are collected, the subset with product a square may be found via a linear algebra subroutine applied to a matrix formed out of the exponents in the prime factorizations of the smooth values. The linear algebra may be done modulo 2.

5. The current formulation of QS involves many improvements, the most notable of them is the *multiple polynomial variation* of James Davis and Peter Montgomery.

6. In 1994, QS was used to factor a 129-digit composite that was the product of a 64-digit prime and a 65-digit prime. This number had been proposed as a challenge to those who would try to crack the famous RSA cryptosystem.

7. In 1985, Hendrik W. Lenstra, Jr. (born 1949) invented the *elliptic curve method* (ECM), which has the advantage that, like trial division, the running time is based on the size of the smallest prime factor. Thus, it can be used to find comparatively small factors of numbers whose size would be prohibitively large for the quadratic sieve. It can be best understood by first examining the $p{-}1$ *method* of John Pollard, Algorithm 3.

8. The Pollard algorithm (Algorithm 3) is successful and efficient if $p{-}1$ happens to be smooth for some prime $p|n$. If the prime factors p of n have the property that $p{-}1$ is not smooth, Algorithm 3 will eventually be successful if a high enough bound B is chosen, but in this case it will not be any more efficient than trial division, Algorithm 1. ECM gets around this restriction on the numbers that can be efficiently factored by randomly searching through various mathematical objects called *elliptic curve groups*, each of which has $p{+}1{-}a$ elements, where $|a| < 2\sqrt{p}$ and a depends on the curve. ECM is successful when a group is encountered such that $p{+}1{-}a$ is a smooth number.

```
Algorithm 3:  $p{-}1$ factorization method.
  input: $n$ (composite number), $B$ (a bound)
  output: a nontrivial factor of $n$
  $b := 2$
  {Loop on $b$}
  if $b|n$ then stop  {$b$ is a prime factor of $n$}
  $M := 1$
  while $M \le B$
      $g := \gcd(b^{\mathrm{lcm}\,(1,2,\ldots,M)} - 1, n)$
      if $n > g > 1$ then output $g$ and stop  {$g$ is a nontrivial factor of $n$}
      else if $g = n$ then choose first prime larger than $b$ and go to beginning of
              the $b$-loop
      else $M := M + 1$
```

9. As of 2016, prime factors as large as 83 digits have been found using ECM. (After such a factor is discovered it may turn out that the remaining part of the number is a prime and the factorization is now complete. This last prime may be very large, as with the tenth and eleventh Fermat numbers; see Table 1 of §4.4.3. In such cases the success of ECM is measured by the *second* largest prime factor in the prime factorization, though in some sense the method has discovered the largest prime factor as well.)

10. The *number field sieve* (NFS), originally suggested by Pollard for numbers of special form, and developed for general composite numbers by Buhler, Lenstra, and Pomerance, is currently the fastest factoring algorithm for very large numbers with no small prime factors.

11. The number field sieve is similar to QS in that one attempts to assemble two squares x^2 and y^2 whose difference is a multiple of n, and this is done via a sieve and linear algebra modulo 2. However, NFS is much more complicated than QS. Although faster for very large numbers, the complexity of the method makes it unsuitable for numbers much smaller than 100 digits. The exact crossover with QS depends a great deal on the implementations and the hardware employed. The two are roughly within an order of magnitude of each other for numbers between 100 and 150 digits, with QS having the edge at the lower end and NFS the edge at the upper end.

12. Part of the NFS algorithm requires expressing a small multiple of the number to be factored by a polynomial of moderate degree. The running time depends, in part, on the size of the coefficients of this polynomial. For Cunningham numbers, this polynomial can be easy to find. (For example, in the notation of §4.4.3, $8F_9 = 8(2^{2^9}+1) = f(2^{103})$, where $f(x) = x^5 + 8$.) This version is called the *special number field sieve* (SNFS). The version for general numbers, the *general number field sieve* (GNFS), has somewhat greater complexity. The greatest success of SNFS has been the factorization of a 180-digit Cunningham number, while the greatest success of GNFS has been the factorization of a 232-digit number of no special form and with no small prime factor.

13. See [Co93], [CrPo05], [Po90], and [Po94] for fuller descriptions of the factoring algorithms described here, as well as others, including the *continued fraction* (CFRAC) method. Until the advent of QS, this had been the fastest known practical algorithm.

14. The factorization algorithms QS, ECM, SNFS, and GNFS are fast in practice, but analyses of their running times depend on heuristic arguments and unproved hypotheses. The fastest algorithm whose running time has been rigorously analyzed is the *class group relations method* (CGRM). It, however, is not practical. It is a probabilistic algorithm whose expected running time is bounded by $e^{c\sqrt{\log n \log\log n}}$, where c tends to 1 as n tends to infinity through the odd composite numbers that are not powers. This result was proved in 1992 by Lenstra and Pomerance.

15. These algorithms are summarized in Table 1. $L(a, b)$ means that the running time to factor n is bounded by $e^{c(\log n)^a(\log\log n)^{1-a}}$, where c tends to b as n tends to infinity through the odd composite non-powers. Running times are measured in the number of arithmetic steps with integers at most the size of n.

Table 1: Comparison of various factoring methods.

algorithm	*year introduced*	*greatest success*	*running time*	*rigorously analyzed*
trial division	antiquity	–	$\sqrt{n}$	yes
CFRAC	1970	63-digit number	$L\left(\frac{1}{2}, \sqrt{\frac{3}{2}}\right)$	no
$p-1$	1974	58-digit factor	–	yes
QS	1981	135-digit number	$L(\frac{1}{2}, 1)$	no
ECM	1985	83-digit factor	$L(\frac{1}{2}, 1)$	no
SNFS	1988	355-digit number	$L\left(\frac{1}{3}, \sqrt[3]{\frac{32}{9}}\right)$	no
CGRM	1992	–	$L(\frac{1}{2}, 1)$	yes
GNFS	1993	221-digit number	$L\left(\frac{1}{3}, \sqrt[3]{\frac{64}{9}}\right)$	no

16. The running time for trial division in Table 1 is a worst-case estimate, achieved when n is prime or the product of two primes of the same magnitude. When n is composite, trial division will discover the least prime factor p of n in roughly p steps. The record for the largest prime factor discovered via trial division is not known, nor is the largest number proved prime by this method, though the feat of Euler of proving that the Mersenne number $2^{31} - 1$ is prime, using only trial division and hand calculations, should certainly be noted. (Euler surely knew, though, that any prime factor of $2^{31} - 1$ is 1 mod 31, so only 1 out of every 31 trial divisors needed to be tested.)

17. The running time of the $p-1$ method is about B, where B is the least number such that for some prime factor p of n, $p - 1$ divides $\operatorname{lcm}(1, 2, \ldots, B)$.

18. There are variants of CFRAC and GNFS that have smaller heuristic complexity estimates, but the ones in Table 1 are for the fastest practical version.

19. The running time bound for ECM is a worst-case estimate. It is more appropriate to measure ECM as a function of the least prime factor p of n. This heuristic complexity bound is $e^{c\sqrt{\log p \log\log p}}$, where c tends to $\sqrt{2}$ as p tends to infinity.

20. The following table lists the largest hard number factored as a function of time. It was compiled with the assistance of Sam Wagstaff. It should be remarked that there is no firm definition of a "hard number". What is meant here is that the number was factored by an algorithm that is not sensitive to any particular form the number may have, nor sensitive to the size of the prime factors.

year	*method*	*digits*
1970	CFRAC	39
1979	CFRAC	46
1982	CFRAC	54
1983	QS	67
1986	QS	87
1988	QS	102
1990	QS	116
1994	QS	129
1995	GNFS	130
1999	GNFS	155
2003	GNFS	174
2005	GNFS	200
2009	GNFS	232

21. It is unknown whether there is a polynomial-time factorization algorithm. Whether there are any factorization algorithms that surpass the quadratic sieve, the elliptic curve method, and the number field sieve in their respective regions of superiority is an area of much current research.

22. A subjective measurement of progress in factorization can be gained by looking at the "ten most wanted numbers" to be factored. The list is maintained by Sam Wagstaff and can be found at `http://homes.cerias.purdue.edu/~ssw/cun//want131`. As of May 2016, "number one" on this list is $2^{1207} - 1$.

23. In 1994 Peter Shor invented an algorithm for factoring integers on a quantum computer that runs in polynomial time. More precisely, this algorithm factors a positive integer n in $O(\log^2 n \log\log n \log\log\log n)$ time. At the present time, only rudimentary quantum computers have been built. Many technological challenges must be solved before useful quantum computing is feasible. As of 2016, the largest integer that has been factored using a quantum computer is 56,153; this was done using an algorithm different from Shor's algorithm.

4.6 ARITHMETIC FUNCTIONS

Functions whose domains are the set of positive integers play an important role in number theory. Such functions are called arithmetic functions and are the subject of this section. The information presented here includes definitions and properties of many important arithmetic functions, asymptotic estimates on the growth of these functions, and algebraic properties of sets of certain arithmetic functions. For more information on the topics covered in this section, see [Ap76].

4.6.1 MULTIPLICATIVE AND ADDITIVE FUNCTIONS

Definitions:

An ***arithmetic function*** is a function that is defined for all positive integers.

An arithmetic function is ***multiplicative*** if $f(mn) = f(m)f(n)$ whenever m and n are relatively prime positive integers.

An arithmetic function is ***completely multiplicative*** if $f(mn) = f(m)f(n)$ for all positive integers m and n.

If f is an arithmetic function, then $\sum_{d|n} f(d)$, the value of the ***summatory function*** of f at n, is the sum of $f(d)$ over all positive integers d that divide n.

An arithmetic function f is ***additive*** if $f(mn) = f(m) + f(n)$ whenever m and n are relatively prime positive integers.

An arithmetic function f is ***completely additive*** if $f(m, n) = f(m) + f(n)$ whenever m and n are positive integers.

Facts:

1. If f is a multiplicative function and $n = p_1^{a_1} p_2^{a_2} \ldots p_s^{a_s}$ is the prime-power factorization of n, then $f(n) = f(p_1^{a_1})f(p_2^{a_2}) \ldots f(p_s^{a_s})$.

2. If f is multiplicative, then $f(1) = 1$.

3. If f is a completely multiplicative function and $n = p_1^{a_1} p_2^{a_2} \ldots p_s^{a_s}$, then $f(n) = f(p_1)^{a_1} f(p_2)^{a_2} \ldots f(p_s)^{a_s}$.

4. If f is multiplicative, then the arithmetic function $F(n) = \sum_{d|n} f(d)$ is multiplicative.

5. If f is an additive function, then $f(1) = 0$.

6. If f is an additive function and a is a positive real number, then $F(n) = a^{f(n)}$ is multiplicative.

7. If f is a completely additive function and a is a positive real number, then $F(n) = a^{f(n)}$ is completely multiplicative.

Examples:

1. The function $f(n) = n^2$ is multiplicative. Even more, it is completely multiplicative.

2. The function $I(n) = \lfloor \frac{1}{n} \rfloor$ (so that $I(1) = 1$ and $I(n) = 0$ if n is a positive integer greater than 1) is completely multiplicative.

3. The Euler phi-function, the number of divisors function, the sum of divisors function, and the Möbius function (defined in subsequent sections) are all multiplicative. None of these functions is completely multiplicative.

4.6.2 EULER'S PHI-FUNCTION

Definition:

If n is a positive integer then $\phi(n)$, the value of the ***Euler phi-function*** at n, is the number of positive integers not exceeding n that are relatively prime to n. The Euler phi-function is also known as the ***totient function***.

Facts:

1. The Euler ϕ function is multiplicative, but not completely multiplicative.

2. If p is a prime, then $\phi(p) = p - 1$.

3. If p is a positive integer with $\phi(p) = p - 1$, then p is prime.

4. If p is a prime and a is a positive integer, then $\phi(p^a) = p^a - p^{a-1}$.

5. If n is a positive integer with prime-power factorization $n = p_1^{a_1} p_2^{a_2} \dots p_k^{a_k}$, then $\phi(n) = n \prod_{j=1}^{k} (1 - \frac{1}{p_j})$.

6. If n is a positive integer greater than 2, then $\phi(n)$ is even.

7. If n has r distinct odd prime factors, then 2^r divides $\phi(n)$.

8. If m and n are positive integers and $\gcd(m, n) = d$, then $\phi(mn) = \frac{\phi(m)\phi(n)d}{\phi(d)}$.

9. If m and n are positive integers and $m|n$, then $\phi(m)|\phi(n)$.

10. If n is a positive integer, then $\sum_{d|n} \phi(d) = \sum_{d|n} \phi(\frac{n}{d}) = n$.

11. If n is a positive integer with $n \geq 5$, then $\phi(n) > \frac{n}{6 \log \log n}$.

12. $\sum_{k=1}^{n} \phi(k) = \frac{3n^2}{\pi^2} + O(n \log n)$

13. $\sum_{k=1}^{n} \frac{\phi(k)}{k} = \frac{6n}{\pi^2} + O(n \log n)$

Examples:

1. Table 1 in §4.6.3 displays the values of $\phi(n)$ for $1 \leq n \leq 1{,}000$.

2. To see that $\phi(10) = 4$, note that the positive integers not exceeding 10 relatively prime to 10 are 1, 3, 7, and 9.

3. To find $\phi(720)$, note that $\phi(720) = \phi(2^4 3^2 5) = 720(1 - \frac{1}{2})(1 - \frac{1}{3})(1 - \frac{1}{5}) = 192$.

4.6.3 SUM AND NUMBER OF DIVISORS FUNCTIONS

Definitions:

If n is a positive integer, then $\sigma(n)$, the value of the ***sum of divisors function*** at n, is the sum of the positive integer divisors of n.

A positive integer n is ***perfect*** if and only if it equals the sum of its proper divisors (or equivalently, if $\sigma(n) = 2n$).

A positive integer n is ***abundant*** if the sum of the proper divisors of n exceeds n (or equivalently, if $\sigma(n) > 2n$).

A positive integer n is ***deficient*** if the sum of the proper divisors of n is less than n (or equivalently, if $\sigma(n) < 2n$).

The positive integers m and n are ***amicable*** if $\sigma(m) = \sigma(n) = m + n$.

If n is a positive integer, then $\tau(n)$, the value of the ***number of divisors function*** at n, is the number of positive integer divisors of n.

Facts:

1. The number of divisors function is multiplicative, but not completely multiplicative.

2. The number of divisors function is the summatory function of $f(n) = 1$; that is, $\tau(n) = \sum_{d|n} 1$.

3. The sum of divisors function is multiplicative, but not completely multiplicative.

4. The sum of divisors function is the summatory function of $f(n) = n$; that is, $\sigma(n) = \sum\limits_{d|n} d$.

5. If n is a positive integer with prime-power factorization $n = p_1^{a_1} p_2^{a_2} \ldots p_k^{a_k}$, then $\sigma(n) = \prod_{j=1}^{k} (p_j^{a_j+1} - 1)/(p_j - 1)$.

6. If n is a positive integer with prime-power factorization $n = p_1^{a_1} p_2^{a_2} \ldots p_k^{a_k}$, then $\tau(n) = \prod_{j=1}^{k} (a_j + 1)$.

7. If n is a positive integer, then $\tau(n)$ is odd if and only if n is a perfect square.

8. If k is an integer greater than 1, then the equation $\tau(n) = k$ has infinitely many solutions.

9. If n is a positive integer, then $(\sum_{d|n} \tau(d))^2 = \sum_{d|n} \tau(d)^3$.

10. A positive integer n is an even perfect number if and only if $n = 2^{m-1}(2^m - 1)$ where m is an integer, $m \geq 2$, and $2^m - 1$ is prime (so that it is a Mersenne prime (§4.4.3)). Hence, the number of known even perfect numbers equals the number of known Mersenne primes.

11. It is unknown whether there are any odd perfect numbers. However, it is known that there are no odd perfect numbers less than 10^{300} and that any odd perfect number must have at least eight different prime factors.

12. $\sum_{k=1}^{n} \sigma(k) = \frac{\pi^2 n^2}{12} + O(n \log n)$.

13. $\sum_{k=1}^{n} \tau(k) = n \log n + (2\gamma - 1)n + O(\sqrt{n})$, where γ is Euler's constant.

14. If m and n are amicable, then m is the sum of the proper divisors of n, and vice versa.

Examples:

1. Table 1 lists the values of $\sigma(n)$ and $\tau(n)$ for $1 \leq n \leq 1{,}000$.

2. To find $\tau(720)$, note that $\tau(720) = \tau(2^4 \cdot 3^2 \cdot 5) = (4+1)(2+1)(1+1) = 30$.

3. To find $\sigma(200)$, note that $\sigma(200) = \sigma(2^3 \cdot 5^2) = \frac{2^4-1}{2-1} \cdot \frac{5^3-1}{5-1} = 15 \cdot 31 = 465$.

4. The integers 6 and 28 are perfect; the integers 9 and 16 are deficient; the integers 12 and 945 are abundant.

5. The integers 220 and 284 form the smallest pair of amicable numbers.

Table 1: Values of $\phi(n)$, $\sigma(n)$, $\tau(n)$, and $\mu(n)$ for $1 \leq n \leq 1000$.

4.6.4 THE MÖBIUS FUNCTION AND OTHER IMPORTANT ARITHMETIC FUNCTIONS

Definitions:

If n is a positive integer, $\mu(n)$, the value of the ***Möbius function***, is defined by

$$\mu(n) = \begin{cases} 1, & \text{if } n = 1 \\ 0, & \text{if } n \text{ has a square factor larger than } 1 \\ (-1)^s, & \text{if } n \text{ is square free and is the product of } s \text{ different primes.} \end{cases}$$

If $n > 1$ is a positive integer, with prime-power factorization $p_1^{a_1} p_2^{a_2} \dots p_m^{a_m}$, then $\lambda(n)$, the value of ***Liouville's function*** at n, is given by $\lambda(n) = (-1)^{a_1+a_2+\cdots+a_m}$, with $\lambda(1) = 1$.

If n is a positive integer with prime-power factorization $n = p_1^{a_1} p_2^{a_2} \dots p_m^{a_m}$, then the arithmetic functions Ω and ω are defined by $\Omega(1) = \omega(1) = 0$ and for $n > 1$, $\Omega(n) = \sum_{i=1}^{m} a_i$ and $\omega(n) = m$. That is, $\Omega(n)$ is the sum of exponents in the prime-power factorization of n and $\omega(n)$ is the number of distinct primes in the prime-power factorization of n.

Facts:

1. The Möbius function is multiplicative, but not completely multiplicative.

2. *Möbius inversion formula*: If f is an arithmetic function and $F(n) = \sum_{d|n} f(d)$, then $f(n) = \sum_{d|n} \mu(d) F(\frac{n}{d})$.

3. If n is a positive integer, then $\phi(n) = \sum_{d|n} \mu(d) \frac{n}{d}$.

4. If f is multiplicative, then $\sum_{d|n} \mu(d) f(d) = \prod_{p|n} (1 - f(p))$.

5. If f is multiplicative, then $\sum_{d|n} \mu(d)^2 f(d) = \prod_{p|n} (1 + f(p))$.

6. If n is a positive integer, then $\sum_{d|n} \mu(d) = \begin{cases} 1 & \text{if } n = 1; \\ 0 & \text{if } n > 1. \end{cases}$

7. If n is a positive integer, then $\sum_{d|n} \lambda(d) = \begin{cases} 1 & \text{if } n \text{ is a perfect square;} \\ 0 & \text{if } n \text{ is not a perfect square.} \end{cases}$

8. In 1897 Mertens showed that $|\sum_{k=1}^{n} \mu(k)| < \sqrt{n}$ for all positive integers n not exceeding 10,000 and conjectured that this inequality holds for all positive integers n. However, in 1985 Odlyzko and teRiele disproved this conjecture, which went by the name *Mertens' conjecture*, without giving an explicit integer n for which the conjecture fails. In 1987 Pintz showed that there is at least one counterexample n with $n \leq 10^{65}$, again without giving an explicit counterexample n. Finding such an integer n requires more computing power than is currently available.

9. Liouville's function is completely multiplicative.

10. The function ω is additive and the function Ω is completely additive.

Examples:

1. Table 1 lists the values of $\mu(n)$ for $1 \leq n \leq 1{,}000$.

2. $\mu(12) = 0$ since $2^2|12$ and $\mu(105) = \mu(3 \cdot 5 \cdot 7) = (-1)^3 = -1$.

3. $\lambda(720) = \lambda(2^4 \cdot 3^2 \cdot 5) = (-1)^{4+2+1} = (-1)^7 = -1$.

4. $\Omega(720) = \Omega(2^4 \cdot 3^2 \cdot 5) = 4 + 2 + 1 = 7$ and $\omega(720) = \omega(2^4 \cdot 3^2 \cdot 5) = 3$.

4.6.5 DIRICHLET PRODUCTS

Definitions:

If f and g are arithmetic functions, then the ***Dirichlet product*** of f and g is the function $f \star g$ defined by $(f \star g)(n) = \sum_{d|n} f(d)g(\frac{n}{d})$.

If f and g are arithmetic functions such that $f \star g = g \star f = I$, where $I(n) = \lfloor \frac{1}{n} \rfloor$, then g is the ***Dirichlet inverse*** of f.

Facts:

1. If f and g are arithmetic functions, then $f \star g = g \star f$.

2. If f, g, and h are arithmetic functions, then $(f \star g) \star h = f \star (g \star h)$.

3. If f, g, and h are arithmetic functions, then $f \star (g + h) = (f \star g) + (f \star h)$.

4. Because of Facts 1–3, the set of arithmetic functions with the operations of Dirichlet product and ordinary addition of functions forms a ring. (See Chapter 5.)

5. If f is an arithmetic function with $f(1) \neq 0$, then there is a unique Dirichlet inverse of f, which is written as f^{-1}. Furthermore, f^{-1} is given by the recursive formulas $f^{-1}(1) = \frac{1}{f(1)}$ and $f^{-1}(n) = -\frac{1}{f(1)} \sum_{\substack{d|n \\ d<n}} f(\frac{n}{d}) f^{-1}(d)$ for $n > 1$.

6. The set of all arithmetic functions f with $f(1) \neq 0$ forms an abelian group with respect to the operation $\star$, where the identity element is the function I.

7. If f and g are arithmetic functions with $f(1) \neq 0$ and $g(1) \neq 0$, then $(f * g)^{-1} = f^{-1} \star g^{-1}$.

8. If u is the arithmetic function with $u(n) = 1$ for all positive integers n, then $\mu \star u = I$, so $u = \mu^{-1}$ and $\mu = u^{-1}$.

9. If f is a multiplicative function, then f is completely multiplicative if and only if $f^{-1}(n) = \mu(n)f(n)$ for all positive integers n.

10. If f and g are multiplicative functions, then $f \star g$ is also multiplicative.

11. If f and g are arithmetic functions and both f and $f \star g$ are multiplicative, then g is also multiplicative.

12. If f is multiplicative, then f^{-1} exists and is multiplicative.

Examples:

1. The identity $\phi(n) = \sum_{d|n} \mu(d)\frac{n}{d}$ (§4.6.4, Fact 3) implies that $\phi = \mu \star N$ where N is the multiplicative function $N(n) = n$.

2. Since the function N is completely multiplicative, $N^{-1} = \mu N$ by Fact 9.

3. From Example 1 and Facts 7 and 8, it follows that $\phi^{-1} = \mu^{-1} \star \mu N = \mu \star \mu N$. Hence $\phi^{-1}(n) = \sum_{d|n} d\mu(d)$.

4.7 PRIMITIVE ROOTS AND QUADRATIC RESIDUES

A primitive root of an integer, when it exists, is an integer whose powers run through a complete system of residues modulo this integer. When a primitive root exists, it is possible to use the theory of indices to solve certain congruences. This section provides the information needed to understand and employ primitive roots.

The question of which integers are perfect squares modulo a prime is one that has been studied extensively. An integer that is a perfect square modulo n is called a quadratic residue of n. The law of quadratic reciprocity provides a surprising link between the answer to the question of whether a prime p is a perfect square modulo a prime q and the answer to the question of whether q is a perfect square modulo p. This section provides information that helps determine whether an integer is a quadratic residue modulo a given integer n.

There are important applications of the topics covered in this section, including applications to public key cryptography and authentication schemes. (See Chapter 15.)

4.7.1 PRIMITIVE ROOTS

Definitions:

If a and m are relatively prime positive integers, then the ***order of a modulo m***, denoted $\text{ord}_m a$, is the least positive integer x such that $a^x \equiv 1 \pmod{m}$.

If r and n are relatively prime integers and n is positive, then r is a ***primitive root modulo m*** if $\text{ord}_n r = \phi(n)$. A primitive root modulo m is also said to be a primitive root of m and m is said to have a primitive root.

If m is a positive integer, then the ***minimum universal exponent modulo m*** is the smallest positive integer $\lambda(m)$ for which $a^{\lambda(m)} \equiv 1 \pmod{m}$ for all integers a relatively prime to m.

Facts:

1. The positive integer n, with $n > 1$, has a primitive root if and only if $n = 2$, 4, p^t, or $2p^t$, where p is an odd prime and t is a positive integer.

2. There are $\phi(d)$ incongruent integers modulo p if p is prime and d is a positive divisor of $p-1$.

3. There are $\phi(p-1)$ primitive roots of p if p is a prime.

4. If the positive integer m has a primitive root, then it has a total of $\phi(\phi(m))$ incongruent primitive roots.

5. If r is a primitive root of the odd prime p, then either r or $r+p$ is a primitive root modulo p^2.

6. If r is a primitive root of p^2, where p is prime, then r is a primitive root of p^k for all positive integers k.

7. It is an unsettled conjecture (stated by E. Artin) whether 2 is a primitive root of infinitely many primes. More generally, given any prime p it is unknown whether p is a primitive root of infinitely many primes.

8. It is known that given any three primes, at least one of these primes is a primitive root of infinitely many primes [GuMu84].

9. Given a set of n primes, $p_1, p_2, \ldots, p_n$, there are $\prod_{k=1}^{n} \phi(p_k - 1)$ integers x with $1 < x \leq \prod_{k=1}^{n} p_k$ such that x is a primitive root of p_k for $k = 1, 2, \ldots, n$. Such an integer x is a called a *common primitive root* of the primes $p_1, \ldots, p_n$.

10. Let g_p denote the smallest positive integer that is a primitive root modulo p, where p is a prime. It is known that g_p is not always small; in particular it has been shown by Fridlender and Salié that there is a positive constant C such that $g_p > C \log p$ for infinitely many primes p [Ri96].

11. Burgess has shown that g_p does not grow too rapidly; in particular he showed that $g_p \leq Cp^{\frac{1}{4}+\epsilon}$ for $\epsilon > 0$, C a constant, and p sufficiently large [Ri96].

12. The minimum universal exponent modulo the powers of 2 are $\lambda(2) = 1$, $\lambda(2^2) = 2$, and $\lambda(2^k) = 2^{k-2}$ for $k = 3, 4, \ldots$.

13. If m is a positive integer with prime-power factorization $2^k q_1^{a_1} \ldots q_r^{a_r}$, where k is a nonnegative integer, then the least universal exponent of m is given by $\lambda(m) = \text{lcm}(\lambda(2^k), \phi(q_1^{a_1}), \ldots, \phi(q_r^{a_r}))$.

14. For every positive integer m, there is an integer a such that $\text{ord}_m a = \lambda(m)$.

15. There are six positive integers m with $\lambda(m) = 2$: $m = 3, 4, 6, 8, 12, 24$.

16. The following table displays the least primitive root ω of each prime less than 10,000.

p	ω	p	ω	p	ω	p	ω	p	ω	p	ω	p	ω	p	ω	p	ω

9941	2	9949	2	9967	3	9973	11										

Examples:

1. Since $2^1 \equiv 2$, $2^2 \equiv 4$, and $2^3 \equiv 1 \pmod 7$, it follows that $\mathrm{ord}_7 2 = 3$.

2. The integers 2, 6, 7, 8 form a complete set of incongruent primitive roots modulo 11.

3. The integer 10 is a primitive root of 487, but it is not a primitive root of 487^2.

4. There are $\phi(6)\phi(10) = 2 \cdot 4 = 8$ common primitive roots of 7 and 11 between 1 and $7 \cdot 11 = 77$. They are the integers 17, 19, 24, 40, 52, 61, 68, 73.

5. From Facts 12 and 13 it follows that the minimum universal exponent of 1,200 is $\lambda(7{,}200) = \lambda(2^5 \cdot 3^2 \cdot 5^2) = \mathrm{lcm}(2^3, \phi(3^2), \phi(5^2)) = \mathrm{lcm}(8, 6, 20) = 120$.

4.7.2 INDEX ARITHMETIC

Definition:

If m is a positive integer with primitive root r and a is an integer relatively prime to m, then the unique nonnegative integer x not exceeding $\phi(m)$ with $r^x \equiv a \pmod m$ is the ***index of a to the base r modulo m***, or the ***discrete logarithm of a to the base r modulo m***.

The index is denoted $\mathrm{ind}_r a$ (where the modulus m is fixed).

Facts:

1. Table 1 displays, for each prime $p < 100$, the indices of all numbers not exceeding p using the least primitive root g of p as the base. If $g^x = y$, the table on the left has a y in position x, while the one on the right has an x in position y.

Table 1: Indices for primes less than 100.

2. If m is a positive integer with primitive root r and a is a positive integer relatively prime to m, then $a \equiv r^{\mathrm{ind}_r a} \pmod{m}$.

3. If m is a positive integer with primitive root r, then $\mathrm{ind}_r 1 = 0$ and $\mathrm{ind}_r r = 1$.

4. If $m > 2$ is an integer with primitive root r, then $\mathrm{ind}_r(-1) = \frac{\phi(m)}{2}$.

5. If m is a positive integer with primitive root r, and a and b are integers relatively prime to m, then

- $\mathrm{ind}_r 1 \equiv 0 \pmod{\phi(m)}$;
- $\mathrm{ind}_r(ab) \equiv \mathrm{ind}_r a + \mathrm{ind}_r b \pmod{\phi(m)}$;
- $\mathrm{ind}_r a^k \equiv k \cdot \mathrm{ind}_r a \pmod{\phi(m)}$ if k is a positive integer.

6. If m is a positive integer, and if r and s are both primitive roots modulo m, then $\mathrm{ind}_r a \equiv \mathrm{ind}_s a \cdot \mathrm{ind}_r s \pmod{\phi(m)}$.

7. If m is a positive integer with primitive root r, and a and b are integers both relatively prime to m, then the exponential congruence $a^x \equiv b \pmod{m}$ has a solution if and only if $\gcd(\mathrm{ind}_r a, \phi(m)) \mid \mathrm{ind}_r b$. Furthermore, if there is a solution to this exponential congruence, then there are exactly $\gcd(\mathrm{ind}_r a, \phi(m))$ incongruent solutions.

8. There are a wide variety of algorithms for computing discrete logarithms, including those known as the baby-step, giant-step algorithm, the Pollard rho algorithm, the Pollig-Hellman algorithm, and the index-calculus algorithm. (See [MeVoVa96].)

9. The fastest algorithms known for computing discrete logarithms, relative to a fixed primitive root, of a given prime p are index-calculus algorithms, which have subexponential computational complexity. In particular, there is an algorithm based on the number field sieve that runs using $L_p(\frac{1}{3}, 1.923) = O(\exp((1.923 + o(1))(\log p)^{\frac{1}{3}}(\log\log p)^{\frac{2}{3}}))$ bit operations. (See [MeVoVa96].)

10. Many cryptographic methods rely on the intractability of finding discrete logarithms of integers relative to a fixed primitive root r of a fixed prime p.

Examples:

1. To solve $3x^{30} \equiv 4 \pmod{37}$ take indices to the base 2 (2 is the smallest primitive root of 37) to obtain $\mathrm{ind}_2(3x^{30}) \equiv \mathrm{ind}_2 4 = 2 \pmod{36}$. Since $\mathrm{ind}_2(3x^{30}) \equiv \mathrm{ind}_2 3 + 30 \cdot \mathrm{ind}_2 x = 26 + 30 \cdot \mathrm{ind}_2 x \pmod{36}$, it follows that $30 \cdot \mathrm{ind}_2 x \equiv 12 \pmod{36}$. The solutions to this congruence are those x such that $\mathrm{ind}_2(x) \equiv 4, 10, 16, 22, 28, 34 \pmod{36}$. From the table of indices (Table 1), the solutions are those x with $x \equiv 16, 25, 9, 21, 12, 28 \pmod{37}$.

2. To solve $7^x \equiv 6 \pmod{17}$ take indices to the base 3 (3 is the smallest primitive root of 17) to obtain $\mathrm{ind}_3(7^x) \equiv \mathrm{ind}_3 6 = 15 \pmod{16}$. Since $\mathrm{ind}_3(7^x) \equiv x \cdot \mathrm{ind}_3 7 \equiv$

$11x \pmod{16}$, it follows that $11x \equiv 15 \pmod{16}$. Since all the steps in this computation are reversible, it follows that the solutions of the original congruence are the solutions of this linear congruence, namely those x with $x \equiv 13 \pmod{16}$.

4.7.3 QUADRATIC RESIDUES

Definitions:

If m and k are positive integers and a is an integer relatively prime to m, then a is a ***kth power residue*** of m if the congruence $x^k \equiv a \pmod{m}$ has a solution.

If a and m are relatively prime integers and m is positive, then a is a ***quadratic residue*** of m if the congruence $x^2 \equiv a \pmod{m}$ has a solution. If $x^2 \equiv a \pmod{m}$ has no solution, then a is a ***quadratic nonresidue*** of m.

If p is an odd prime and p does not divide a, then the ***Legendre symbol*** $\left(\frac{a}{p}\right)$ is 1 if a is a quadratic residue of p and -1 if a is a quadratic nonresidue of p. This symbol is named after the French mathematician Adrien-Marie Legendre (1752–1833).

If n is an odd positive integer with prime-power factorization $n = p_1^{t_1} p_2^{t_2} \ldots p_m^{t_m}$ and a is an integer relatively prime to n, then the ***Jacobi symbol*** $\left(\frac{a}{n}\right)$ is defined by

$$\left(\frac{a}{n}\right) = \prod_{i=1}^{m} \left(\frac{a}{p_i}\right)^{t_i},$$

where the symbols on the right-hand side of the equality are Legendre symbols. This symbol is named after the German mathematician Carl Gustav Jacob Jacobi (1804–1851).

Let a be a positive integer that is not a perfect square and such that $a \equiv 0$ or $1 \pmod{4}$. The ***Kronecker symbol*** (named after the German mathematician Leopold Kronecker (1823–1891)), which is a generalization of the Legendre symbol, is defined as

- $\left(\frac{a}{2}\right) = \begin{cases} 1 & \text{if } a \equiv 1 \pmod{8} \\ -1 & \text{if } a \equiv 5 \pmod{8} \end{cases}$
- $\left(\frac{a}{p}\right) =$ the Legendre symbol $\left(\frac{a}{p}\right)$ if p is an odd prime such that p does not divide a
- $\left(\frac{a}{n}\right) = \prod_{j=1}^{r} \left(\frac{a}{p_j}\right)^{t_j}$ if $\gcd(a, n) = 1$ and $n = \prod_{j=1}^{r} p_j{}^{t_j}$ is the prime factorization of n.

Facts:

1. If p is an odd prime, then there are an equal number of quadratic residues modulo p and quadratic nonresidues modulo p among the integers $1, 2, \ldots, p-1$. In particular, there are $\frac{p-1}{2}$ integers of each type in this set.

2. *Euler's criterion*: If p is an odd prime and a is a positive integer not divisible by p, then $\left(\frac{a}{p}\right) \equiv a^{(p-1)/2} \pmod{p}$.

3. If p is an odd prime, and a and b are integers not divisible by p with $a \equiv b \pmod{p}$, then $\left(\frac{a}{p}\right) = \left(\frac{b}{p}\right)$.

4. If p is an odd prime, and a and b are integers not divisible by p, then $\left(\frac{a}{p}\right)\left(\frac{b}{p}\right) = \left(\frac{ab}{p}\right)$.

5. If p is an odd prime, and a and b are integers not divisible by p, then $\left(\frac{a^2}{p}\right) = 1$.

6. If p is an odd prime, then $\left(\frac{-1}{p}\right) = \begin{cases} 1 & \text{if } p \equiv 1 \pmod{4} \\ -1 & \text{if } p \equiv -1 \pmod{4}. \end{cases}$

7. If p is an odd prime, then -1 is a quadratic residue of p if $p \equiv 1 \pmod{4}$ and a quadratic nonresidue of p if $p \equiv -1 \pmod{4}$. (This is a direct consequence of Fact 6.)

8. *Gauss' lemma*: If p is an odd prime, a is an integer with $\gcd(a,p) = 1$, and s is the number of least positive residues of $a, 2a, \ldots, \frac{p-1}{2}a$ greater than $\frac{p}{2}$, then $\left(\frac{a}{p}\right) = (-1)^s$.

9. If p is an odd prime, then $\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8}$.

10. The integer 2 is a quadratic residue of all primes p with $p \equiv \pm 1 \pmod{8}$ and a quadratic nonresidue of all primes $p \equiv \pm 3 \pmod{8}$. (This follows from Fact 9.)

11. *Law of quadratic reciprocity*: If p and q are odd primes, then

$$\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{p-1}{2}\cdot\frac{q-1}{2}}.$$

This law was first proved by Carl Friedrich Gauss (1777–1855).

12. Many different proofs of the law of quadratic reciprocity have been discovered. By one count, there are more than 150 different proofs. Gauss published eight different proofs himself.

13. The law of quadratic reciprocity implies that if p and q are odd primes, then $\left(\frac{p}{q}\right) = \left(\frac{q}{p}\right)$ if either $p \equiv 1 \pmod{4}$ or $q \equiv 1 \pmod{4}$, and $\left(\frac{p}{q}\right) = -\left(\frac{q}{p}\right)$ if $p \equiv q \equiv 3 \pmod{4}$.

14. If m is an odd positive integer, and a and b are integers relatively prime to m with $a \equiv b \pmod{m}$, then $\left(\frac{a}{m}\right) = \left(\frac{b}{m}\right)$.

15. If m is an odd positive integer, and a and b are integers relatively prime to m, then $\left(\frac{ab}{m}\right) = \left(\frac{a}{m}\right)\left(\frac{b}{m}\right)$.

16. If m is an odd positive integer and a is an integer relatively prime to m, then $\left(\frac{a^2}{m}\right) = 1$.

17. If m and n are relatively prime odd positive integers, and a is an integer relatively prime to m and n, then $\left(\frac{a}{mn}\right) = \left(\frac{a}{m}\right)\left(\frac{a}{n}\right)$.

18. If m is an odd positive integer, then the value of the Jacobi symbol $\left(\frac{a}{m}\right)$ does not determine whether a is a perfect square modulo m.

19. If m is an odd positive integer, then $\left(\frac{-1}{m}\right) = (-1)^{\frac{m-1}{2}}$.

20. If m is an odd positive integer, then $\left(\frac{2}{m}\right) = (-1)^{\frac{m^2-1}{8}}$.

21. *Reciprocity law for Jacobi symbols*: If m and n are relatively prime odd positive integers, then

$$\left(\frac{m}{n}\right)\left(\frac{n}{m}\right) = (-1)^{\frac{m-1}{2}\frac{n-1}{2}}.$$

22. The number of integers in a reduced set of residues modulo n with $\left(\frac{k}{n}\right) = 1$ equals the number with $\left(\frac{k}{n}\right) = -1$.

23. The Legendre symbol $\left(\frac{a}{p}\right)$, where p is prime and $0 \leq a < p$, can be evaluated using $O((\log_2 p)^2)$ bit operations.

24. The Jacobi symbol $\left(\frac{a}{n}\right)$, where n is a positive integer and $0 \leq a < n$, can be evaluated using $O((\log_2 n)^2)$ bit operations.

25. Let p be an odd prime. Even though half the integers x with $1 \leq x < p$ are quadratic nonresidues of p, there is no known polynomial-time deterministic algorithm for finding such an integer. However, picking integers at random produces a probabilistic algorithm that has 2 as the expected number of iterations done before a nonresidue is found.

26. Let m be a positive integer with a primitive root. If k is a positive integer and a is an integer relatively prime to m, then a is a kth power residue of m if and only if $a^{\phi(m)/d} \equiv 1 \pmod{m}$ where $d = \gcd(k, \phi(m))$. Moreover, if a is a kth power residue of m, then there are exactly d incongruent solutions modulo m of the congruence $x^k \equiv a \pmod{m}$.

27. If p is a prime, k is a positive integer, and a is an integer with $\gcd(a, p) = 1$, then a is a kth power residue of p if and only if $a^{(p-1)/d} \equiv 1 \pmod{p}$, where $d = \gcd(k, p - 1)$.

28. The kth roots of a kth power residue modulo p, where p is a prime, can be computed using a primitive root and indices to this primitive root. This is only practical for small primes p. (See §4.7.1.)

Examples:

1. The integers 1, 3, 4, 5, and 9 are quadratic residues of 11; the integers 2, 6, 7, 8, and 10 are quadratic nonresidues of 11. Hence $\left(\frac{1}{11}\right) = \left(\frac{3}{11}\right) = \left(\frac{4}{11}\right) = \left(\frac{5}{11}\right) = \left(\frac{9}{11}\right) = 1$ and $\left(\frac{2}{11}\right) = \left(\frac{6}{11}\right) = \left(\frac{7}{11}\right) = \left(\frac{8}{11}\right) = \left(\frac{10}{11}\right) = -1$.

2. To determine whether 11 is a quadratic residue of 19, note that using the law of quadratic reciprocity (Fact 11) and Facts 3, 4, and 10 it follows that $\left(\frac{11}{19}\right) = -\left(\frac{19}{11}\right) = -\left(\frac{8}{11}\right) = -\left(\frac{2}{11}\right)^3 = -(-1)^3 = 1$.

3. To evaluate the Jacobi symbol $\left(\frac{2}{45}\right)$, note that $\left(\frac{2}{45}\right) = \left(\frac{2}{3^2 \cdot 5}\right) = \left(\frac{2}{3}\right)^2 \cdot \left(\frac{2}{5}\right) = (-1)^2(-1) = -1$.

4. The Jacobi symbol $\left(\frac{5}{21}\right) = 1$, but 5 is not a quadratic residue of 21.

5. The integer 6 is a fifth power residue of 101 since $6^{(101-1)/5} = 6^{20} \equiv 1 \pmod{101}$.

6. From Example 5 it follows that 6 is a fifth power residue of 101. The solutions of the congruence $x^5 \equiv 6 \pmod{101}$, the fifth roots of 6, can be found by taking indices to the primitive root 2 modulo 101. Since $\mathrm{ind}_2 6 = 70$, this gives $\mathrm{ind}_2 x^5 = 5 \cdot \mathrm{ind}_2 x \equiv 70 \pmod{100}$. The solutions of this congruence are the integers x with $\mathrm{ind}_2 x \equiv 14 \pmod{20}$. This implies that the fifth roots of 6 are the integers with $\mathrm{ind}_2 x = 14$, 34, 54, 74, and 94. These are the integers x with $x \equiv 22$, 70, 85, 96, and 30 (mod 101).

7. The integer 5 is not a sixth power residue of 17 since $5^{\frac{16}{\gcd(6,16)}} = 5^8 \equiv -1 \pmod{17}$.

4.7.4 MODULAR SQUARE ROOTS

Definition:

If m is a positive integer and a is an integer, then r is a ***square root of a modulo m*** if $r^2 \equiv a \pmod{m}$.

Facts:

1. If p is a prime of the form $4n + 3$ and a is a perfect square modulo p, then the two square roots of a modulo p are $\pm a^{(p+1)/4}$.

2. If p is a prime of the form $8n + 5$ and a is a perfect square modulo p, then the two square roots of a modulo p are $x \equiv \pm a^{(p+3)/8} \pmod{p}$ if $a^{(p-1)/4} \equiv 1 \pmod{p}$ and $x \equiv \pm 2^{(p-1)/4} a^{(p+3)/8} \pmod{p}$ if $a^{(p-1)/4} \equiv -1 \pmod{p}$.

3. If n is a positive integer that is the product of two distinct primes p and q, and a is a perfect square modulo n, then there are four distinct square roots of a modulo n. These square roots can be found by finding the two square roots of a modulo p and the two square roots of a modulo q and then using the Chinese remainder theorem to find the four square roots of a modulo n.

4. A square root of an integer a that is a square modulo p, where p is an odd prime, can be found by an algorithm that uses an average of $O((\log_2 p)^3)$ bit operations. (See [MeVoVa96].)

5. If n is an odd integer with r distinct prime factors, a is a perfect square modulo n, and $\gcd(a, n) = 1$, then a has exactly 2^r incongruent square roots modulo n.

Examples:

1. Using Legendre symbols it can be shown that 11 is a perfect square modulo 19. Using Fact 1 it follows that the square roots of 11 modulo 19 are given by $x \equiv \pm 11^{(19+1)/4} = \pm 11^5 \equiv \pm 7 \pmod{19}$.

2. There are four incongruent square roots of 860 modulo $11021 = 103 \cdot 107$. To find these solutions, first note that $x^2 \equiv 860 = 36 \pmod{103}$ so that $x \equiv \pm 6 \pmod{103}$ and $x^2 \equiv 860 = 4 \pmod{107}$ so that $x \equiv \pm 2 \pmod{107}$. The Chinese remainder theorem can be used to find these square roots. They are $x \equiv -212, -109, 109, 212 \pmod{11021}$.

3. The square roots of 121 modulo 315 are 11, 74, 101, 151, 164, 214, 241, and 304. As predicted by Fact 5, $121 = 11^2$ has $2^3 = 8$ square roots modulo $315 = 3^2 \cdot 5 \cdot 7$.

4.8 DIOPHANTINE EQUATIONS

An important area of number theory is devoted to finding solutions of equations where the solutions are restricted to belong to the set of integers, or some other specified set, such as the set of rational numbers. An equation with the added proviso that the solutions must be integers (or must belong to some other specified countable set, such as the set of rational numbers) is called a *diophantine equation*. This name comes from the ancient Greek mathematician Diophantus (ca. 250 A.D.), who wrote extensively on such equations.

Diophantine equations have both practical and theoretical importance. Their practical importance arises when variables in an equation represent quantities of objects, for example. Fermat's last theorem, which states that there are no nontrivial solutions in integers $n > 2$, x, y, and z to the diophantine equation $x^n + y^n = z^n$ has long interested mathematicians and non-mathematicians alike. This theorem was proved only in the mid-1990s, even though many brilliant scholars sought a proof during the last three centuries.

More information about diophantine equations can be found in [Di71], [Gu94], and [Mo69].

4.8.1 LINEAR DIOPHANTINE EQUATIONS

Definition:

A ***linear diophantine equation*** is an equation of the form $a_1x_1 + a_2x_2 + \cdots + a_nx_n = c$, where $c, a_1, \ldots, a_n$ are integers and where integer solutions are sought for the unknowns $x_1, x_2, \ldots, x_n$.

Facts:

1. Let a and b be integers with $\gcd(a,b)=d$. The linear diophantine equation $ax+by=c$ has no solutions if $d \not| c$. If $d|c$, then there are infinitely many solutions in integers. Moreover, if $x=x_0$, $y=y_0$ is a particular solution, then all solutions are given by $x=x_0+\frac{b}{d}n$, $y=y_0-\frac{a}{d}n$, where n is an integer.

2. A linear diophantine equation $a_1x_1+a_2x_2+\cdots+a_nx_n=c$ has solutions in integers if and only if $\gcd(a_1,a_2,\ldots,a_n)|c$. In that case, there are infinitely many solutions.

3. A solution (x_0,y_0) of the linear diophantine equation $ax+by=c$ where $\gcd(a,b)|c$ can be found by first expressing $\gcd(a,b)$ as a linear combination of a and b, and then multiplying by $c/\gcd(a,b)$. (See §4.2.1.)

4. A linear diophantine equation $a_1x_1+a_2x_2+\cdots+a_nx_n=c$ in n variables can be solved by a reduction method. To find a particular solution, first let $b=\gcd(a_2,\ldots,a_n)$ and let (x_1,y) be a solution of the diophantine equation $a_1x_1+by=c$. Iterate this procedure on the diophantine equation in $n-1$ variables, $a_2x_2+a_3x_3+\cdots+a_nx_n=y$ until an equation in two variables is obtained.

5. The solution to a system of r linear diophantine equations in n variables is obtained by using Gaussian elimination (§6.4.2) to reduce to a single diophantine equation in two or more variables.

6. If a and b are relatively prime positive integers and n is a positive integer, then the diophantine equation $ax+by=n$ has a *nonnegative* integer solution if $n\geq(a-1)(b-1)$.

7. If a and b are relatively prime positive integers, then there are exactly $(a-1)(b-1)/2$ nonnegative integers n less than $ab-a-b$ such that the equation $ax+by=n$ has a nonnegative solution.

8. If a and b are relatively prime positive integers, then there are no nonnegative solutions of $ax+by=ab-a-b$.

Examples:

1. To solve the linear diophantine equation $17x+13y=100$, express $\gcd(17,13)=1$ as a linear combination of 17 and 13. Using the steps of the Euclidean algorithm, it follows that $4\cdot 13-3\cdot 17=1$. Multiplying by 100 yields $100=400\cdot 13-300\cdot 17$. Since a particular solution is $x=-300$, $y=400$, all solutions are then given by $x=-300+13n$, $y=400-17n$, where n ranges over the set of integers.

2. A traveller has exactly \$510 in travelers checks where each check is either a \$20 or a \$50 check. How many checks of each denomination can there be?

The answer to this question is given by the set of solutions in nonnegative integers to the linear diophantine equation $20x+50y=510$. There are infinitely many solutions in integers, which can be shown to be given by $x=-102+5n$, $y=51-2n$. Since both x and y must be nonnegative, it follows that $n=21$, 22, 23, 24, or 25. Therefore there could be three \$20 checks and nine \$50 checks, eight \$20 checks and seven \$50 checks, thirteen \$20 checks and five \$50 checks, eighteen \$20 checks and three \$50 checks, or twenty-three \$20 checks and one \$50 check.

3. The linear diophantine equation $12x_1+21x_2+9x_3+15x_4=9$ has infinitely many solutions since $\gcd(12,21,9,15)=3$, which divides 9. To find a particular solution, first divide both sides of the equation by 3 to get $4x_1+7x_2+3x_3+5x_4=3$. Now $1=\gcd(7,3,5)$, so solve $4x_1+1y=3$, as in Example 1, to get $x_1=1$, $y=-1$. Next we solve $7x_2+3x_3+5x_4=-1$. Since $1=\gcd(3,5)$, solve $7x_2+1z=-1$ to get $x_2=1$, $z=-8$. Finally, solve $3x_3+5x_4=-8$ to get $x_3=-1$, $x_4=-1$. This gives the particular solution $x=(1,1,-1,-1)$.

4. To solve the following system of linear diophantine equations in integers

$$\begin{aligned} x + y + z + w &= 100 \\ x + 2y + 3z + 4w &= 300 \\ x + 4y + 9z + 16w &= 1000, \end{aligned}$$

first reduce the system by elimination to

$$\begin{aligned} x + y + z + w &= 100 \\ y + 2z + 3w &= 200 \\ 2z + 6w &= 300. \end{aligned}$$

The solution to the last equation is $z = 150 + 3t$, $w = -t$, where t is an integer. Back-substitution gives

$$\begin{aligned} y &= 200 - 2(150 + 3t) - 3(-t) = -100 - 3t \\ x &= 100 - (-100 - 3t) - (150 + 3t) - (-t) = 50 + t. \end{aligned}$$

4.8.2 PYTHAGOREAN TRIPLES

Definitions:

A ***Pythagorean triple*** is a solution (x, y, z) of the equation $x^2 + y^2 = z^2$, where x, y, and z are positive integers.

A Pythagorean triple is ***primitive*** if $\gcd(x, y, z) = 1$.

Facts:

1. Pythagorean triples represent the lengths of sides of right triangles.

2. All primitive Pythagorean triples are given by

$$x = 2mn,\ y = m^2 - n^2,\ z = m^2 + n^2$$

where m and n are relatively prime positive integers of opposite parity with $m > n$.

3. All Pythagorean triples can be found by taking

$$x = 2mnt,\ y = (m^2 - n^2)t,\ z = (m^2 + n^2)t$$

where t is a positive integer and m and n are as in Fact 2.

4. Given a Pythagorean triple (x, y, z) with y odd, then m and n from Fact 2 can be found by taking $m = \sqrt{\frac{z+y}{2}}$ and $n = \sqrt{\frac{z-y}{2}}$.

5. The following table lists all Pythagorean triples with $z \leq 100$.

m	n	$x = 2mn$	$y = m^2 - n^2$	$z = m^2 + n^2$
2	1	4	3	5
3	1	6	8	10
3	2	12	5	13
4	1	8	15	17
4	2	16	12	20

m	n	$x = 2mn$	$y = m^2 - n^2$	$z = m^2 + n^2$
4	3	24	7	25
5	1	10	24	26
5	2	20	21	29
5	3	30	16	34
5	4	40	9	41
6	1	12	35	37
6	2	24	32	40
6	3	36	27	45
6	4	48	20	52
6	5	60	11	61
7	1	14	48	50
7	2	28	45	53
7	3	42	40	58
7	4	56	33	65
7	5	70	24	74
7	6	84	13	85
8	1	16	63	65
8	2	32	60	68
8	3	48	55	73
8	4	64	48	80
8	5	80	39	89
8	6	96	28	100
9	1	18	80	82
9	2	36	77	85
9	3	54	72	90
9	4	72	65	97

6. The solutions of the diophantine equation $x^2 + y^2 = 2z^2$ can be obtained by transforming this equation into $\left(\frac{x+y}{2}\right)^2 + \left(\frac{x-y}{2}\right)^2 = z^2$, which shows that $(\frac{x+y}{2}, \frac{x-y}{2}, z)$ is a Pythagorean triple. All solutions are given by $x = (m^2 - n^2 + 2mn)t$, $y = (m^2 - n^2 - 2mn)t$, $z = (m^2 + n^2)t$ where m, n, and t are integers.

7. The solutions of the diophantine equation $x^2 + 2y^2 = z^2$ are given by $x = (m^2 - 2n^2)t$, $y = 2mnt$, $z = m^2 + 2n^2$ where m, n, and t are positive integers.

8. The solutions of the diophantine equation $x^2 + y^2 + z^2 = w^2$ where y and z are even are given by $x = \frac{m^2+n^2-r^2}{r}$, $y = 2m$, $z = 2n$, $w = \frac{m^2+n^2+r^2}{r}$, where m and n are positive integers and r runs through the divisors of $m^2 + n^2$ less than $(m^2 + n^2)^{1/2}$.

9. The solutions of the diophantine equation $x^2 + y^2 = z^2 + w^2$, with $x > z$, are given by $x = \frac{ms+nr}{2}$, $y = \frac{ns-mr}{2}$, $z = \frac{ms-nr}{2}$, $w = \frac{ns+mr}{2}$, where if m and n are both odd, then r and s are either both odd or both even.

4.8.3 FERMAT'S LAST THEOREM

Definitions:

The ***Fermat equation*** is the diophantine equation $x^n + y^n = z^n$, where x, y, z are integers and n is a positive integer greater than 2.

A ***nontrivial solution*** to the Fermat equation $x^n+y^n = z^n$ is a solution in integers x, y, and z in which none of x, y, and z are zero.

Let p be an odd prime and let $\mathcal{K} = \mathcal{Q}(\omega)$ be the degree-p cyclotomic extension of the rational numbers (§5.6.2). If p does not divide the class number of $\mathcal{K}$ (see [Co93]), then p is said to be ***regular***. Otherwise p is ***irregular***.

Facts:

1. *Fermat's last theorem*: The statement that the diophantine equation $x^n + y^n = z^n$ has no nontrivial solutions in the positive integers for $n \geq 3$, is called *Fermat's last theorem.* The statement was made more than 300 years ago by Pierre de Fermat (1601–1665) and resisted proof until recently.

2. Fermat wrote in the margin of his copy of the works of Diophantus, next to the discussion of the equation $x^2+y^2 = z^2$, the following: "However, it is impossible to write a cube as the sum of two cubes, a fourth power as the sum of two fourth powers and in general any power the sum of two similar powers. For this I have discovered a truly wonderful proof, but the margin is too small to contain it." In spite of this quotation, no proof was found of this statement until 1994, even though many mathematicians actively worked on finding such a proof. Most mathematicians would find it shocking if Fermat actually had found a proof.

3. Fermat's last theorem was finally proved in 1994 by Andrew Wiles [Wi95]. Wiles collected the Wolfskehl Prize, worth approximately $50,000 in 1997 for this proof.

4. That there are no nontrivial solutions of the Fermat equation for $n = 4$ was demonstrated by Fermat with an elementary proof using the *method of infinite descent.* This method proceeds by showing that for every solution in positive integers, there is a solution such that the values of each of the integers x, y, and z is smaller, contradicting the well-ordering property of the set of integers.

5. The method of infinite descent invented by Fermat can be used to show that the more general diophantine equation $x^4 + y^4 = z^2$ has no nontrivial solutions in integers x, y, and z.

6. The diophantine equation $x^4 - y^4 = z^2$ has no nontrivial solutions, as can be shown using the method of infinite descent.

7. The sum of two cubes may equal the sum of two other cubes. That is, there are nontrivial solutions of the diophantine equation $x^3+y^3 = z^3+w^3$. The smallest solution is $x = 1$, $y = 12$, $z = 9$, $w = 10$.

8. The sum of three cubes may also be a cube. In fact, the solutions of $x^3+y^3+z^3 = w^3$ are given by $x = 3a^2+5b(a-b)$, $y = 4a(a-b)+6b^2$, $z = 5a(a-b)-3b^2$, $w = 6a^2-4b(a+b)$ where a and b are integers.

9. Euler conjectured that there were four fourth powers of positive integers whose sum is also the fourth power of an integer. In other words, he conjectured that there are nontrivial solutions to the diophantine equation $v^4 + w^4 + x^4 + y^4 = z^4$. The first such example was found in 1911 when it was discovered (by R. Norrie) that $30^4 + 120^4 + 272^4 + 315^4 = 353^4$.

10. Euler also conjectured that the sum of the fourth powers of three positive integers can never be the fourth power of an integer and that the sum of fifth powers of four positive integers can never be the fifth power of an integer, and so on. In other words, he conjectured that there were no nontrivial solutions to the diophantine equations $w^4 + x^4 + y^4 = z^4$, $v^5 + w^5 + x^5 + y^5 = z^5$, and so on. He was mistaken. The smallest counterexamples known are $95{,}800^4 + 217{,}519^4 + 414{,}560^4 = 422{,}481^4$ and $27^5 + 84^5 + 110^5 + 133^5 = 144^5$.

11. If $n = mp$ for some integer m and p is prime, then the Fermat equation can be rewritten as $(x^m)^p + (y^m)^p = (z^m)^p$. Since the only positive integers greater than 2 without an odd prime factor are powers of 2 and $x^4 + y^4 = z^4$ has no nontrivial solutions in integers, Fermat's last theorem can be demonstrated by showing that $x^p + y^p = z^p$ has no nontrivial solutions in integers x, y, and z when p is an odd prime.

12. An odd prime p is regular if and only if it does not divide the numerator of any of the numbers $B_2, B_4, \ldots, B_{p-3}$, where B_k is the kth Bernoulli number. (See §3.1.4.)

13. There is a relatively simple proof of Fermat's last theorem for exponents that are regular primes.

14. The smallest irregular primes are 37, 59, 67, 101, 103, 149, and 157.

15. Wiles' proof of Fermat's last theorem is based on the theory of elliptic curves. The proof is based on relating to integers a, b, c, and n that supposedly satisfy the Fermat equation $a^n + b^n = c^n$ the elliptic curve $y^2 = x(x + a^n)(x - b^n)$ (called the *associated Frey curve*) and deriving a contradiction using sophisticated results from the theory of elliptic curves.

For more details, see Wiles' original proof [Wi95], the popular account [Si97], and the following two sites:

4.8.4 PELL'S, BACHET'S, AND CATALAN'S EQUATIONS

Definitions:

Pell's equation is a diophantine equation of the form $x^2 - dy^2 = 1$, where d is a square-free positive integer. This diophantine equation is named after John Pell (1611–1685).

Bachet's equation is a diophantine equation of the form $y^2 = x^3 + k$. This diophantine equation is named after Claude Gaspar Bachet (1587–1638).

Catalan's equation is the diophantine equation $x^m - y^n = 1$, where a solution is sought with integers $x > 0$, $y > 0$, $m > 1$, and $n > 1$. This diophantine equation is named after Eugène Charles Catalan (1814–1894).

Facts:

1. If x, y is a solution to the diophantine equation $x^2 - dy^2 = n$ with d square free and $n^2 < d$, then the rational number $\frac{x}{y}$ is a convergent of the simple continued fraction for $\sqrt{d}$. (See §4.9.2.)

2. An equation of the form $ax'^2 + bx' + c = y'^2$ can be transformed by means of the relations $x = 2ax' + b$ and $y = 2y'$ into an equation of the form $x^2 - dy^2 = n$, where $n = b^2 - 4ac$ and $d = a$.

3. It is ironic that John Pell apparently had little to do with finding the solutions to the diophantine equation $x^2 - dy^2 = 1$. Euler gave this equation its name following a mistaken reference. Fermat conjectured an infinite number of solutions to this equation in 1657; this was eventually proved by Lagrange in 1768.

4. Let x, y be the least positive solution to $x^2 - dy^2 = 1$, with d square free. Then every positive solution is given by

$$x_k + y_k\sqrt{d} = (x + y\sqrt{d})^k,$$

where k ranges over the positive integers.

5. The following table gives the smallest positive solutions to Pell's equation $x^2 - dy^2 = 1$ with d a square-free positive integer less than 100.

d	x	y
2	3	2
3	2	1
5	9	4
6	5	2

73	2,281,249	267,000
74	3,699	430
77	351	40
78	53	6
79	80	9
82	163	18
83	82	9
85	285,769	30,996
86	10,405	1,122
87	28	3
89	500,001	53,000
91	1,574	165
93	12,151	1,260
94	2,143,295	221,064
95	39	4
97	62,809,633	6,377,352

6. If $k = 0$, then the formulae $x = t^2, y = t^3$ give an infinite number of solutions to the Bachet equation $y^2 = x^3 + k$.

7. There are no solutions to Bachet's equation for the following values of k: -144, -105, -78, -69, -42, -34, -33, -31, -24, -14, -5, 7, 11, 23, 34, 45, 58, 70.

8. The following table lists solutions to Bachet's equation for various values of k.

k	x
0	t^2 (t any integer)
1	$0, -1, 2$
17	$-1, -2, 2, 4, 8, 43, 52, 5334$
-2	3
-4	$2, 5$
-7	$2, 32$
-15	1

9. If $k < 0$, k is square free, $k \equiv 2$ or $3 \pmod 4$, and the class number of the field $\mathcal{Q}(\sqrt{-k})$ is not a multiple of 3, then the only solution of the Bachet equation $y^2 = x^3 + k$ for x is given by whichever of $-(4k \pm 1)/3$ is an integer. The first few values of such k are 1, 2, 5, 6, 10, 13, 14, 17, 21, and 22.

10. Solutions to the Catalan equation give consecutive integers that are powers of integers.

11. The Catalan equation has the solution $x = 3$, $y = 2$, $m = 2$, $n = 3$, so $8 = 2^3$ and $9 = 3^2$ are consecutive powers of integers. The *Catalan conjecture* is that this is the only solution.

12. Levi ben Gerson showed in the 14th century that 8 and 9 are the only consecutive powers of 2 and 3, so that the only solution in positive integers of $3^m - 2^n = \pm 1$ is $m = 2$ and $n = 3$.

13. Euler proved that the only solution in positive integers of $x^3 - y^2 = \pm 1$ is $x = 2$ and $y = 3$.

14. Lebesgue showed in 1850 that $x^m - y^2 = 1$ has no solutions in positive integers when m is an integer greater than 3.

15. The diophantine equations $x^3 - y^n = 1$ and $x^m - y^3 = 1$ with $m > 2$ were shown to have no solutions in positive integers in 1921, and in 1964 it was shown that $x^2 - y^n = 1$ has no solutions in positive integers.

16. R. Tijdeman showed in 1976 that there are only finitely many solutions in integers to the Catalan equation $x^m - y^n = 1$ by showing that there is a computable constant C such that for every solution, $x^m < C$ and $y^n < C$. However, the enormous size of the constant C makes it infeasible to establish the Catalan conjecture using this result.

17. In 2002 Catalan's conjecture was proved by Preda Mihăilescu using the theories of cyclotomic fields and Galois modules. Consequently, the statement that Catalan's equation has exactly one solution (given in Fact 11) is now called Mihăilescu's theorem.

Examples:

1. To solve the diophantine equation $x^2 - 13y^2 = 1$, note that the simple continued fraction for $\sqrt{13}$ is $[3; \overline{1, 1, 1, 1, 6}]$, with convergents $3, 4, \frac{7}{2}, \frac{11}{3}, \frac{18}{5}, \frac{119}{33}, \frac{137}{38}, \frac{256}{71}, \frac{393}{109}, \frac{649}{180}, \ldots$. The smallest positive solution to the equation is $x = 649$, $y = 180$. A second solution is given by $(649 + 180\sqrt{13})^2 = 842{,}401 + 233{,}640\sqrt{13}$, that is, $x = 842{,}401$, $y = 233{,}640$.

2. Congruence considerations can be used to show that there are no solutions of Bachet's equation for $k = 7$. Modulo 8, every square is congruent to 0, 1, or 4; therefore if x is even, then $y^2 \equiv 7 \pmod 8$, a contradiction. Likewise if $x \equiv 3 \pmod 4$, then $y^2 \equiv 2 \pmod 8$, also impossible. So assume that $x \equiv 1 \pmod 4$. Add one to both sides and factor to get $y^2 + 1 = x^3 + 8 = (x+2)(x^2 - 2x + 4)$. Now $x^2 - 2x + 4 \equiv 3 \pmod 4$, so it must have a prime divisor $p \equiv 3 \pmod 4$. Then $y^2 \equiv -1 \pmod p$, which implies that -1 is a quadratic residue modulo p. (See §4.7.3.) But $p \equiv 3 \pmod 4$, so -1 cannot be a quadratic residue modulo p. Therefore, there are no solutions when $k = 7$.

4.8.5 SUMS OF SQUARES AND WARING'S PROBLEM

Definitions:

If k is a positive integer, then $g(k)$ is the smallest positive integer such that every positive integer can be written as a sum of $g(k)$ kth powers.

If k is a positive integer, then $G(k)$ is the smallest positive integer such that every *sufficiently large* positive integer can be written as a sum of $G(k)$ kth powers.

The determination of $g(k)$ is called ***Waring's problem***. (Edward Waring, 1741–1793)

Facts:

1. A positive integer n is the sum of two squares if and only if each prime factor of n of the form $4k+3$ appears to an even power in the prime factorization of n.

2. If $m = a^2 + b^2$ and $n = c^2 + d^2$, then the number mn can be expressed as the sum of two squares as follows: $mn = (ac+bd)^2 + (ad-bc)^2$.

3. If n is representable as the sum of two squares, then it is representable in $4(d_1 - d_2)$ ways (where the order of the squares and their signs matter), where d_1 is the number of divisors of n of the form $4k+1$ and d_2 is the number of divisors of n of the form $4k+3$.

4. An integer n is the sum of three squares if and only if n is not of the form $4^m(8k+7)$, where m is a nonnegative integer.

5. The positive integers less than 100 that are not the sum of three squares are $7, 15, 23, 28, 31, 39, 47, 55, 60, 63, 71, 79, 87, 92$, and 95.

6. *Lagrange's four-square theorem*: Every positive integer is the sum of 4 squares, some of which may be zero. (Joseph Lagrange, 1736–1813)

7. A useful lemma due to Lagrange is the following. If $m = a^2 + b^2 + c^2 + d^2$ and $n = e^2 + f^2 + g^2 + h^2$, then mn can be expressed as the sum of four squares as follows: $mn = (ae+bf+cg+dh)^2 + (af-be+ch-dg)^2 + (ag-ce+df-bh)^2 + (ah-de+bg-cf)^2$.

8. The number of ways n can be written as the sum of four squares is $8(s - s_4)$, where s is the sum of the divisors of n and s_4 is the sum of the divisors of n that are divisible by 4.

9. It is known that $g(k)$ always exists.

10. For $6 \leq k \leq 471{,}600{,}000$ the following formula holds except possibly for a finite number of positive integers k: $g(k) = \lfloor (\frac{3}{2})^k \rfloor + 2^k - 2$ where $\lfloor x \rfloor$ represents the floor (greatest integer) function.

11. The exact value of $G(k)$ is known only for two values of k, $G(2) = 4$ and $G(4) = 16$.

12. From Facts 6 and 11, it follows that $G(2) = g(2) = 4$.

13. If k is an integer with $k \geq 2$, then $G(k) \leq g(k)$.

14. If k is an integer with $k \geq 2$, then $G(k) \geq k+1$.

15. Hardy and Littlewood showed that $G(k) \leq (k-2)2^{k-1}+5$ and conjectured that $G(k) < 2k+1$ when k is not a power of 2 and $G(k) < 4k$ when k is a power of 2.

16. The best upper bound known for $G(k)$ is $G(k) < ck\log k$ for some constant c.

17. The known values and established estimates for $g(k)$ and $G(k)$ for $2 \leq k \leq 8$ are given in the following table.

$g(2) = 4$	$G(2) = 4$
$g(3) = 9$	$4 \leq G(3) \leq 7$
$g(4) = 19$	$G(4) = 16$
$g(5) = 37$	$6 \leq G(5) \leq 17$
$g(6) = 73$	$9 \leq G(6) \leq 24$
$143 \leq g(7) \leq 3{,}806$	$8 \leq G(7) \leq 33$
$279 \leq g(8) \leq 36{,}119$	$32 \leq G(8) \leq 42$

18. There are many related diophantine equations concerning sums and differences of powers. For instance $x = 1$, $y = 12$, $z = 9$, and $w = 10$ is the smallest solution to $x^3 + y^3 = z^3 + w^3$.

4.9 DIOPHANTINE APPROXIMATION

Diophantine approximation is the study of how closely a number θ can be approximated by numbers of some particular kind. Usually θ is an irrational (real) number, and the goal is to approximate θ using rational numbers $\frac{p}{q}$. Standard references are [Ca57] and [Sc80].

4.9.1 CONTINUED FRACTIONS

Definitions:

A ***continued fraction*** is a (finite or infinite) expression of the form

$$a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cfrac{1}{\ddots}}}}$$

The terms $a_0, a_1, \ldots$ are called the ***partial quotients***. If the partial quotients are all integers, and $a_i \geq 1$ for $i \geq 1$, then the continued fraction is said to be ***simple***. For convenience, the above expression is usually abbreviated as $[a_0, a_1, a_2, a_3, \ldots]$.

A continued fraction that has an expansion with a block that repeats after some point is called ***ultimately periodic***. The ultimately periodic continued fraction expansion $[a_0, a_1, \ldots, \; a_N, a_{N+1}, \ldots, a_{N+k}, a_{N+1}, \ldots, a_{N+k}, a_{N+1}, \ldots]$ is often abbreviated as $[a_0, a_1, \ldots, a_N, \overline{a_{N+1}, \ldots, a_{N+k}}]$. The terms $a_0, a_1, \ldots, a_N$ are called the ***pre-period*** and the terms $a_{N+1}, a_{N+2}, \ldots, a_{N+k}$ are called the ***period***.

Facts:

1. Every irrational number has a unique expansion as a simple continued fraction.

2. Every rational number has exactly two simple continued fraction expansions, one with an odd number of terms and one with an even number of terms. Of these, the one with the larger number of terms ends with 1.

3. The simple continued fraction for a real number r is finite if and only if r is rational.

4. The simple continued fraction for a real number r is infinite and ultimately periodic if and only if r is a quadratic irrational.

5. The simple continued fraction for $\sqrt{d}$, where d a positive integer that is not a square, is as follows: $\sqrt{d} = [a_0, \overline{a_1, a_2, \ldots, a_n, 2a_0}\,]$, where the sequence $(a_1, a_2, \ldots, a_n)$ is a palindrome.

6. The following table illustrates the three types of continued fractions.

type	*kind of number*	*example*
finite	rational	$\frac{355}{113} = [3, 7, 16]$
ultimately periodic	quadratic irrational	$\sqrt{2} = [1, 2, 2, 2, \ldots]$
infinite, but not ultimately periodic	neither rational nor quadratic irrational	$\pi = [3, 7, 15, 1, 292, \ldots]$

7. The continued fraction for a real number can be computed by Algorithm 1.

```
Algorithm 1: The continued fraction algorithm.
  procedure $CFA(x$: real number)
  $i := 0$
  $x_0 := x$
  $a_0 := \lfloor x_0 \rfloor$
  output($a_0$)
  while $(x_i \neq a_i)$
    $x_{i+1} := \frac{1}{x_i - a_i}$
    $i := i + 1$
    $a_i := \lfloor x_i \rfloor$
    output($a_i$)
  {Return the finite or infinite sequence $(a_0, a_1, \ldots)$}
```

8. The following table gives continued fractions for $\sqrt{d}$, with d square free and $d \leq 100$.

d	$\sqrt{d}$	d	$\sqrt{d}$
2	$[1, \overline{2}]$	53	$[7, \overline{3, 1, 1, 3, 14}]$
3	$[1, \overline{1, 2}]$	54	$[7, \overline{2, 1, 6, 1, 2, 14}]$
5	$[2, \overline{4}]$	55	$[7, \overline{2, 2, 2, 14}]$
6	$[2, \overline{2, 4}]$	56	$[7, \overline{2, 14}]$

40	$[6,\overline{3,12}]$	88	$[9,\overline{2,1,1,1,2,18}]$
41	$[6,\overline{2,2,12}]$	89	$[9,\overline{2,3,3,2,18}]$
42	$[6,\overline{2,12}]$	90	$[9,\overline{2,18}]$
43	$[6,\overline{1,1,3,1,5,1,3,1,1,12}]$	91	$[9,\overline{1,1,5,1,5,1,1,18}]$
44	$[6,\overline{1,1,1,2,1,1,1,12}]$	92	$[9,\overline{1,1,2,4,2,1,1,18}]$
45	$[6,\overline{1,2,2,2,1,12}]$	93	$[9,\overline{1,1,1,4,6,4,1,1,1,18}]$
46	$[6,\overline{1,3,1,1,2,6,2,1,1,3,1,12}]$	94	$[9,\overline{1,2,3,1,1,5,1,8,1,5,1,1,3,2,1,18}]$
47	$[6,\overline{1,5,1,12}]$	95	$[9,\overline{1,2,1,18}]$
48	$[6,\overline{1,12}]$	96	$[9,\overline{1,3,1,18}]$
50	$[7,\overline{14}]$	97	$[9,\overline{1,5,1,1,1,1,1,1,5,1,18}]$
51	$[7,\overline{7,14}]$	98	$[9,\overline{1,8,1,18}]$
52	$[7,\overline{4,1,2,1,4,14}]$	99	$[9,\overline{1,18}]$

9. Continued fraction expansions for certain quadratic irrationals are given in the following table.

d	*continued fraction expansion for* $\sqrt{d}$
$\sqrt{n^2-1}$	$[\,n-1, \overline{1, 2n-2}\,]$
$\sqrt{n^2-2}$	$[\,n-1, \overline{1, n-2, 1, 2n-2}\,]$
$\sqrt{n^2+1}$	$[\,n, \overline{2n}\,]$
$\sqrt{n^2+2}$	$[\,n, \overline{n, 2n}\,]$
$\sqrt{n^2-n}$	$[\,n-1, \overline{2, 2n-2}\,]$
$\sqrt{n^2+n}$	$[\,n, \overline{2, 2n}\,]$
$\sqrt{4n^2+4}$	$[\,2n, \overline{n, 4n}\,]$
$\sqrt{4n^2-n}$	$[\,2n-1, \overline{1, 2, 1, 4n-2}\,]$
$\sqrt{4n^2+n}$	$[\,2n, \overline{4, 4n}\,]$
$\sqrt{9n^2+2n}$	$[\,3n, \overline{3, 6n}\,]$

10. Continued fraction expansions for some famous numbers are given in the following table.

number	*continued fraction expansion*
π	$[\,3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, 14, 2, 1, 1, 2, 2, 2, 2, 1, 84, 2, 1, 1, 15, 3, \ldots]$
γ	$[\,0, 1, 1, 2, 1, 2, 1, 4, 3, 13, 5, 1, 1, 8, 1, 2, 4, 1, 1, 40, 1, 11, 3, 7, 1, 7, 1, 1, 5, \ldots]$
$\sqrt[3]{2}$	$[\,1, 3, 1, 5, 1, 1, 4, 1, 1, 8, 1, 14, 1, 10, 2, 1, 4, 12, 2, 3, 2, 1, 3, 4, 1, 1, 2, 14, \ldots]$
$\log 2$	$[\,0, 1, 2, 3, 1, 6, 3, 1, 1, 2, 1, 1, 1, 1, 3, 10, 1, 1, 1, 2, 1, 1, 1, 1, 3, 2, 3, 1, 13, 7, \ldots]$
e	$[\,2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, \ldots]$
$e^{\frac{1}{n}}$	$[\,1,\ n-1,\ 1, 1,\ 3n-1,\ 1, 1,\ 5n-1,\ 1, 1,\ 7n-1, \ldots]$
$e^{\frac{2}{2n+1}}$	$[\,1,\ \overline{(6n+3)k+n,\ (24n+12)k+12n+6,\ (6n+3)k+5n+2,\ 1,\ 1}_{k\geq 0}\,]$
$\tanh\frac{1}{n}$	$[\,0,\ n,\ 3n,\ 5n,\ 7n, \ldots]$
$\tan\frac{1}{n}$	$[\,0, n-1, 1, 3n-2, 1, 5n-2, 1, 7n-2, 1, 9n-2, \ldots]$
$\frac{1+\sqrt{5}}{2}$	$[\,1, 1, 1, 1, \ldots]$

Examples:

1. To find the continued fraction representation of $\frac{62}{23}$, apply Algorithm 1 to obtain

$$\tfrac{62}{23} = 2 + \frac{1}{\frac{23}{16}}, \quad \tfrac{23}{16} = 1 + \frac{1}{\frac{16}{7}}, \quad \tfrac{16}{7} = 2 + \frac{1}{\frac{7}{2}}, \quad \tfrac{7}{2} = 3 + \frac{1}{2}.$$

Combining these equations shows that $\frac{62}{23} = [2, 1, 2, 3, 2]$. Since $2 = 1 + \frac{1}{1}$, it also follows that $\frac{62}{23} = [2, 1, 2, 3, 1, 1]$.

2. Applying Algorithm 1 to find the continued fraction of $\sqrt{6}$, it follows that

$$a_0 = \lfloor\sqrt{6}\rfloor = 2, \quad a_1 = \lfloor\tfrac{\sqrt{6}+2}{2}\rfloor = 2, \quad a_2 = \lfloor\sqrt{6}+2\rfloor = 4, \quad a_3 = a_1, \quad a_4 = a_2, \ldots .$$

Hence $\sqrt{6} = [\,2, \overline{2, 4}\,]$.

3. The continued fraction expansion of e is $e = [2, 1, 2, 1, 1, 4, 1, 1, 6, \ldots]$. This expansion is often abbreviated as $[\,2, \overline{1, 2k, 1}_{k\geq 1}\,]$. (See [Pe54].)

4.9.2 CONVERGENTS

Definitions:

Let $p_{-2} = 0$, $q_{-2} = 1$, $p_{-1} = 1$, $q_{-1} = 0$, and define $p_n = a_n p_{n-1} + p_{n-2}$ and $q_n = a_n q_{n-1} + q_{n-2}$ for $n \geq 0$. Then $\frac{p_n}{q_n} = [a_0, a_1, \ldots, a_n]$. The fraction $\frac{p_n}{q_n}$ is called the nth ***convergent***.

Facts:

1. $p_n q_{n-1} - p_{n-1} q_n = (-1)^{n+1}$ for $n \geq 0$.

2. Let $\theta = [\,a_0, a_1, a_2, \ldots]$ be an irrational number. Then $\left|\theta - \frac{p_n}{q_n}\right| < \frac{1}{a_{n+1} q_n^2}$.

3. If $n > 1$, $0 < q \leq q_n$, and $\frac{p}{q} \neq \frac{p_n}{q_n}$, then $\left|\theta - \frac{p}{q}\right| > \left|\theta - \frac{p_n}{q_n}\right|$.

4. $[\ldots, a, b, 0, c, d, \ldots] = [\ldots, a, b + c, d, \ldots]$.

5. Almost all real numbers have unbounded partial quotients.

6. For almost all real numbers, the frequency with which the partial quotient k occurs is $\log_2\!\left(1 + \frac{1}{k(k+2)}\right)$. Hence, the partial quotient 1 occurs about 41.5% of the time, the partial quotient 2 occurs about 17.0% of the time, etc.

7. For almost all real numbers,

$$\lim_{n\to\infty} (a_1 a_2 \ldots a_n)^{\frac{1}{n}} = K \approx 2.68545.$$

K is called *Khintchine's constant*.

8. *Lévy's law*: For almost all real numbers,

$$\lim_{n\to\infty} (p_n)^{\frac{1}{n}} = \lim_{n\to\infty} (q_n)^{\frac{1}{n}} = e^{\frac{\pi^2}{12 \log 2}}.$$

Examples:

1. We compute the first eight convergents to π as follows:

$n =$	-2	-1	0	1	2	3	4	5	6	7	8
$a_n =$			3	7	15	1	292	1	1	1	2
$p_n =$	0	1	3	22	333	355	103,993	104,348	208,341	312,689	833,719
$q_n =$	1	0	1	7	106	113	33,102	33,215	66,317	99,532	265,381

2. In order to find a rational fraction $\frac{p}{q}$ in lowest terms that approximates e to within 10^{-6}, we compute the convergents q_n until $a_{n+1}(q_n)^2 < 10^{-6}$:

$n =$	-2	-1	0	1	2	3	4	5	6	7	8	9	10
$a_n =$			2	1	2	1	1	4	1	1	6	1	1
$p_n =$	0	1	2	3	8	11	19	87	106	193	1,264	1,457	2,721
$q_n =$	1	0	1	1	3	4	7	32	39	71	465	536	1,001

Hence, $\frac{2721}{1001} \approx 2.71828171$ is the desired fraction.

4.9.3 APPROXIMATION THEOREMS

Facts:

1. *Dirichlet's theorem*: If θ is irrational, then

$$\left|\theta - \tfrac{p}{q}\right| < \tfrac{1}{q^2}$$

for infinitely many p, q.

2. *Dirichlet's theorem in d dimensions*: If $\theta_1, \theta_2, \ldots, \theta_d$ are real numbers with at least one θ_i irrational, then

$$\left|\theta_i - \tfrac{p_i}{q}\right| < \tfrac{1}{q^{1+\frac{1}{d}}}$$

for infinitely many $p_1, p_2, \ldots, p_d, q$.

3. *Hurwitz's theorem*: If θ is an irrational number, then

$$\left|\theta - \tfrac{p}{q}\right| < \tfrac{1}{\sqrt{5}q^2}$$

for infinitely many p, q. The constant $\sqrt{5}$ is best possible.

4. *Liouville's theorem*: Let θ be an irrational algebraic number of degree n. Then there exists a constant c (depending on θ) such that

$$\left|\theta - \tfrac{p}{q}\right| > \tfrac{c}{q^n}$$

for all rationals $\frac{p}{q}$ with $q > 0$. The number θ is called a *Liouville number* if $\left|\theta - \frac{p}{q}\right| < q^{-n}$ has a solution for all $n \geq 0$. An example of a Liouville number is $\sum_{k\geq 1} 2^{-k!}$.

5. *Roth's theorem*: Let θ be an irrational algebraic number, and let ϵ be any positive number. Then

$$\left|\theta - \tfrac{p}{q}\right| > \tfrac{1}{q^{2+\epsilon}}$$

for all but finitely many rationals $\frac{p}{q}$ with $q > 0$.

4.9.4 IRRATIONALITY MEASURES

Definitions:

Let θ be a real irrational number. Then the real number μ is said to be an ***irrationality measure*** for θ if for every $\epsilon > 0$ there exists a positive real $q_0 = q_0(\epsilon)$ such that $|\theta - \frac{p}{q}| > q^{-(\mu+\epsilon)}$ for all integers p, q with $q > q_0$.

Fact:

1. The following table shows the best irrationality measures known for some important numbers.

number θ	*measure* μ	*discoverer*
π	7.6064	Salikhov (2008)
π^2	5.4413	Rhin and Viola (1996)
$\zeta(3)$	5.5139	Rhin and Viola (2001)
$\log 2$	3.5746	Marcovecchio (2009)
$\frac{\pi}{\sqrt{3}}$	4.2304	Androsenko (2015)

4.10 ALGEBRAIC NUMBER THEORY

When working on questions involving integers or rational numbers, one is often led to look at extensions of the rational numbers. These yield rings of algebraic integers, which have many properties similar to the usual integers. A notable exception is the frequent lack of unique factorization into primes.

Many classical questions can be rephrased in terms of algebraic number theory, for example, factorization of polynomials modulo primes. The number field sieve, which is based on algebraic number theory, is the strongest general purpose factorization algorithm currently being used. Algebraic number theory is an active subject of research and remains a basic tool in diophantine equations and in many other areas of mathematics.

Standard references are [La00], [IrRo98], [Mu11], [StTa16], and [Wa97].

4.10.1 BASIC CONCEPTS

Definitions:

A complex number α is an ***algebraic number*** if it is a root of a monic polynomial with rational coefficients. (A ***monic polynomial*** is a polynomial with leading coefficient equal to 1.)

An algebraic number α is an ***algebraic integer*** if it is a root of a monic polynomial with integer coefficients.

If α is an algebraic number with minimal polynomial $f(x)$ of degree n, then the $n-1$ other roots of $f(x)$ are called the ***conjugates*** of α.

If α and β are algebraic integers and there is an algebraic integer γ such that $\alpha\gamma = \beta$, then α ***divides*** β, written $\alpha|\beta$.

An algebraic number α is of ***degree*** n if it is a root of a monic polynomial with rational coefficients of degree n but is not a root of any monic polynomial with rational coefficients of degree less than n.

The ***integers*** of an algebraic number field are the algebraic integers that belong to this field.

A ***number field*** is a field that is a finite degree extension of $\mathcal{Q}$.

An algebraic integer ϵ is a ***unit*** if there exists an algebraic integer γ such that $\epsilon\gamma = 1$.

Facts:

1. The integers are the only rational numbers that are algebraic integers.

2. Sums and products of algebraic integers are algebraic integers, so the algebraic integers in a field form a ring.

3. Each element of a number field is an algebraic number.

Examples:

1. Two of the most common examples of number fields are quadratic fields and cyclotomic fields. (See §4.10.2 and §4.10.6.)

2. The numbers $2+\sqrt{3}$ and $2-\sqrt{3}$ are algebraic integers because they are roots of the polynomial X^2-4X+1. They are conjugates of each other. They are units because $(2+\sqrt{3})(2-\sqrt{3})=1$.

3. $1/\sqrt{2}$ is an algebraic number but is not an algebraic integer. It is a root of the polynomial is $X^2-(1/2)$, which does not have integer coefficients, and there is no monic polynomial with integer coefficients that has $1/\sqrt{2}$ as a root.

4. The minimal polynomial of $\sqrt[3]{2}$ is X^3-2. The other roots of this polynomial are $\omega\sqrt[3]{2}$ and $\omega^2\sqrt[3]{2}$, where ω is a primitive cube root of unity, so these are the conjugates of $\sqrt[3]{2}$.

5. Let $i=\sqrt{-1}$. The field $\mathcal{Q}(i)=\{a+bi \mid a,b\in\mathcal{Q}\}$ is a number field of degree 2.

6. The field $\mathcal{Q}(\sqrt[3]{2})=\{a+b\sqrt[3]{2}+c\sqrt[3]{4} \mid a,b,c\in\mathcal{Q}\}$ is a number field of degree 3.

7. The algebraic integers in $\mathcal{Q}(\sqrt[3]{2})$ are $\mathcal{Z}[\sqrt[3]{2}]=\{a+b\sqrt[3]{2}+c\sqrt[3]{4} \mid a,b,c\in\mathcal{Z}\}$.

8. Algebraic numbers arise naturally when solving diophantine equations involving integers. (See §4.10.4, Example 6.)

4.10.2 QUADRATIC FIELDS

Definitions:

If $d\neq 1$ is a square-free integer, then $\mathcal{Q}(\sqrt{d})=\{a+b\sqrt{d} \mid a \text{ and } b \text{ are rational numbers}\}$ is called a ***quadratic field***. If $d>1$, then $\mathcal{Q}(\sqrt{d})$ is called a ***real quadratic field***; if $d<0$, then $\mathcal{Q}(\sqrt{d})$ is called an ***imaginary quadratic field***.

A number α in $\mathcal{Q}(\sqrt{d})$ is a ***quadratic integer*** (or an ***integer*** when the context is clear) if α is an algebraic integer.

The integers of $\mathcal{Q}(\sqrt{-1})$ are called the ***Gaussian integers***. (These are the numbers in $\mathcal{Z}[i]=\{a+bi \mid a,b \text{ are integers}\}$. See §5.4.2.)

If $\alpha=a+b\sqrt{d}$ belongs to $\mathcal{Q}(\sqrt{d})$, then its ***conjugate***, denoted by $\overline{\alpha}$, is the number $a-b\sqrt{d}$.

If α belongs to $\mathcal{Q}(\sqrt{d})$, then the ***norm*** of α is the number $N(\alpha)=\alpha\overline{\alpha}$.

Facts:

1. The integers of the field $\mathcal{Q}(\sqrt{d})$, where d is a square-free integer, are the numbers $a+b\sqrt{d}$ when $d\equiv 2$ or $3 \pmod 4$. When $d\equiv 1 \pmod 4$, the integers of the field are the numbers $\frac{a+b\sqrt{d}}{2}$, where a and b are integers which are either both even or both odd.

2. If $d<0$, $d\neq -1$, $d\neq -3$, then there are exactly two units, ± 1, in $\mathcal{Q}(\sqrt{d})$. There are exactly four units in $Q(\sqrt{-1})$, namely ± 1 and $\pm i$. There are exactly six units in $\mathcal{Q}(\sqrt{-3})$: ± 1, $\pm\frac{-1+\sqrt{-3}}{2}$, $\pm\frac{-1-\sqrt{-3}}{2}$.

3. If $d>1$, there are infinitely many units in $\mathcal{Q}(\sqrt{d})$. Furthermore, there is a unit $\epsilon_0>1$, called the *fundamental unit* of $\mathcal{Q}(\sqrt{d})$, such that all units are of the form $\pm\epsilon_0^n$ where n is an integer.

Examples:

1. The conjugate of $-2+3i$ in the ring of Gaussian integers is $-2-3i$. Consequently, $N(-2+3i)=(-2-3i)(-2+3i)=13$.

2. The number $1+\sqrt{2}$ is a fundamental unit of $\mathcal{Q}(\sqrt{2})$. Therefore, all units are of the form $\pm(1+\sqrt{2})^n$ where $n=0,\pm1,\pm2,\ldots$.

4.10.3 PRIMES AND UNIQUE FACTORIZATION IN QUADRATIC FIELDS

Definitions:

An integer π in $\mathcal{Q}(\sqrt{d})$, not zero or a unit, is ***irreducible*** in $\mathcal{Q}(\sqrt{d})$ if, whenever $\pi=\alpha\beta$ where α and β are integers in $\mathcal{Q}(\sqrt{d})$, either α or β is a unit.

An integer π in $\mathcal{Q}(\sqrt{d})$, not zero or a unit, is ***prime*** in $\mathcal{Q}(\sqrt{d})$ if, whenever $\pi \mid \alpha\beta$ where α and β are integers in $\mathcal{Q}(\sqrt{d})$, either $\pi \mid \alpha$ or $\pi \mid \beta$.

If α and β are nonzero integers in $\mathcal{Q}(\sqrt{d})$ and $\alpha=\beta\epsilon$ where ϵ is a unit, then β is called an ***associate*** of α.

A quadratic field $\mathcal{Q}(\sqrt{d})$ is a ***Euclidean field*** with respect to the norm if, given integers α and β in $\mathcal{Q}(\sqrt{d})$ where β is not zero, there are integers δ and γ in $\mathcal{Q}(\sqrt{d})$ such that $\alpha=\gamma\beta+\delta$ and $|N(\delta)|<|N(\beta)|$.

A quadratic field $\mathcal{Q}(\sqrt{d})$ has the ***unique factorization property*** if whenever $\alpha\neq 0$ is a non-unit integer in $\mathcal{Q}(\sqrt{d})$ with two factorizations $\alpha=\epsilon\pi_1\pi_2\ldots\pi_r=\epsilon'\pi_1'\pi_2'\ldots\pi_s'$ where ϵ and ϵ' are units and each π_i and π_j' is prime, then $r=s$ and the primes π_i and π_j' can be paired off into pairs of associates.

Facts:

1. If α is an integer in $\mathcal{Q}(\sqrt{d})$ and $N(\alpha)$ is an integer that is prime, then α is irreducible.

2. The integers of $\mathcal{Q}(\sqrt{d})$ are a unique factorization domain if and only if every irreducible is prime.

3. A Euclidean quadratic field has the unique factorization property.

4. The quadratic field $\mathcal{Q}(\sqrt{d})$ is Euclidean if and only if d is one of the following integers: $-11,-7,-3,-2,-1,2,3,5,6,7,11,13,17,19,21,29,33,37,41,57,73$.

5. If $d<0$, then the imaginary quadratic field $\mathcal{Q}(\sqrt{d})$ has the unique factorization property if and only if $d=-1,-2,-3,-7,-11,-19,-43,-67$, or -163. This theorem was stated as a conjecture by Gauss in the 19th century and was proved in the 1960s by Harold Stark and Alan Baker independently.

6. In 1952, the engineer Kurt Heegner (1893–1965) had published a proof of the result of Baker and Stark, but it was not accepted because it relied on some defective statements of Heinrich Weber. After the proofs by Baker and Stark, the gaps in Heegner's proof were filled in by Stark, Max Deuring, and Bryan Birch, independently.

7. It is unknown whether infinitely many real quadratic fields $\mathcal{Q}(\sqrt{d})$ have the unique factorization property.

8. Of the 60 real quadratic fields $\mathcal{Q}(\sqrt{d})$ with $2\le d\le 100$, exactly 38 have the unique factorization property, namely those with $d=2$, 3, 5, 6, 7, 11, 13 14, 17, 19, 21, 22, 23, 29, 31, 33, 37, 38, 41, 43, 46, 47, 53, 57, 59, 61, 62, 67, 69, 71, 73, 77, 83, 86, 89, 93, 94, and 97.

9. The *Cohen-Lenstra heuristics* [CoLe84] predict that, as p runs through the primes $p\equiv 1 \pmod 4$, approximately 75.446% of the fields $\mathcal{Q}(\sqrt{p})$ have the unique factorization property.

Examples:

1. The number $2+i$ is an irreducible Gaussian integer. This follows since its norm $N(2+i)=(2+i)(2-i)=5$ is a prime integer. Its associates are itself and the three Gaussian integers $(-1)(2+i)=-2-i$, $i(2+i)=-1+2i$, and $-i(2+i)=1-2i$.

2. The integers of $\mathcal{Q}(\sqrt{-5})$ are the numbers of the form $a+b\sqrt{-5}$, where a and b are integers. The field $\mathcal{Q}(\sqrt{-5})$ does not have the unique factorization property. To see this, note that $6 = 2\cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$ and each of 2, 3, $1+\sqrt{-5}$, and $1-\sqrt{-5}$ are irreducibles in this quadratic field. For example, to see that $1+\sqrt{-5}$ is irreducible, suppose that $1+\sqrt{-5}=(a+b\sqrt{-5})(c+d\sqrt{-5})$. This implies that $6=(a^2+5b^2)(c^2+5d^2)$, which is impossible unless $a=\pm1$, $b=0$ or $c=\pm1$, $d=0$. Consequently, one of the factors must be a unit.

4.10.4 GENERAL NUMBER FIELDS

Definitions:

If I and J are ideals of the ring of algebraic integers of a number field, I ***divides*** J if there exists an ideal I' of this ring such that $II'=J$.

Let K be a number field of degree n over $\mathcal{Q}$. Choose algebraic integers $\beta_1,\dots,\beta_n$ in K such that every algebraic integer in K is a linear combination of $\beta_1,\dots,\beta_n$ with integer coefficients. Form the $n\times n$ matrix (a_{ij}), where the ijth entry is the trace from K to $\mathcal{Q}$ of $\beta_i\beta_j$. The ***discriminant*** of K, denoted D_K, is the determinant of the matrix (a_{ij}).

Two nonzero ideals I_1 and I_2 of the ring of algebraic integers of a number field K are in the same ***ideal class*** if there is an element x in the field such that $I_1 = xI_2$, where the latter is the set $\{xi \mid i\in I_2\}$.

The set of ideal classes forms a group, called the ***ideal class group*** of K.

The order of the ideal class group is called the ***class number*** of K, and is often denoted h or h_K.

If α and β are algebraic integers in a number field K and I is an ideal of the ring of integers of K, then α is ***congruent*** to β mod I, written $\alpha\equiv\beta \pmod{I}$, if $\alpha-\beta\in I$.

Let K be a number field and let $\mathcal{O}_K$ be the ring of algebraic integers in K. Let I be a nonzero ideal of $\mathcal{O}_K$. The ***norm*** of I, denoted $N(I)$, is the order of $\mathcal{O}_K/I$.

Let K be a number field of degree n over $\mathcal{Q}$. Write $K=\mathcal{Q}(\alpha)$ for some α, and let $m(X)$ be the minimal polynomial of α. This polynomial has r_1 real roots and r_2 pairs of complex roots. The numbers r_1 and r_2 are called the ***number of real embeddings*** of K and the ***number of pairs of complex embeddings***, respectively.

Facts:

1. Algebraic number theory arose from attempts to generalize the law of quadratic reciprocity (see §4.7.3) to higher power reciprocity laws.

2. Cubic reciprocity is best stated using the Eisenstein integers, namely the algebraic integers $\mathcal{Z}[\omega]$, where ω is a primitive cube root of unity. Let π_1 and π_2 be two primes of $\mathcal{Z}[\omega]$ that are relatively prime to each other and do not divide 3. The *cubic residue symbol* $\left(\frac{\pi_1}{\pi_2}\right)_3$ is the unique power of ω satisfying

$$\pi_1^{(N(\pi_2)-1)/3} \equiv \left(\frac{\pi_1}{\pi_2}\right)_3 \pmod{\pi_2}.$$

3. *Cubic reciprocity* says that if π_1 and π_2 are congruent to 2 modulo 3, then

$$\left(\frac{\pi_1}{\pi_2}\right)_3 = \left(\frac{\pi_2}{\pi_1}\right)_3 .$$

This was proved by Gotthold Eisenstein (1823–1852), Gauss, and others.

4. Gauss proved a quartic (or biquadratic) reciprocity law in the context of the Gaussian integers $\mathcal{Z}[i]$, where $i = \sqrt{-1}$.

5. Ernst Kummer (1810–1893) studied pth power reciprocity laws for odd primes p in the context of the pth cyclotomic field $\mathcal{Q}(\zeta)$ (see §4.10.6), where ζ is a primitive pth root of unity.

6. Kummer realized that unique factorization can fail in cyclotomic fields and was thus led to his theory of ideal numbers (in modern terminology, these are essentially ring homomorphisms from the ring of integers of a cyclotomic field to a finite field; see [Ma77]) and ideal class groups.

7. Richard Dedekind (1831–1916) reinterpreted Kummer's ideal numbers as ideals in the ring of algebraic integers.

8. In modern language, Kummer showed that every nonzero ideal is uniquely a product of prime ideals.

9. The ideal class group is a finite abelian group.

10. The class number of a number field K is 1 if and only if the ring of algebraic integers in K is a unique factorization domain.

11. The concept of the class number of a number field can be useful for finding solutions to diophantine equations in integers. See Example 7 and §4.10.6, Example 3.

12. Let $K = \mathcal{Q}(\sqrt{d})$, where $d \neq 1$ is a square-free integer that can be chosen positive or negative. The discriminant D_K is $4d$ if $d \equiv 2, 3 \pmod 4$, and d if $d \equiv 1 \pmod 4$.

13. If I and J are nonzero ideals of the ring of algebraic integers of a number field, then I divides J if and only if $J \subseteq I$.

14. Let K be a number field, let r_1 be the number of real embeddings of K, and let r_2 be the number of pairs of complex embeddings. Let W_K be the group of roots of unity contained in K. The *Dirichlet unit theorem* says that the group of units of the ring of algebraic integers in K is the direct sum of W_K and a free abelian group of rank $r_1 + r_2 - 1$.

15. The *Minkowski bound* says that if K is a number field of degree n over $\mathcal{Q}$ with r_2 pairs of complex embeddings, then each ideal class contains an ideal I with

$$1 \leq N(I) \leq \tfrac{n!}{n^n} \left(\tfrac{4}{\pi}\right)^{r_2} \sqrt{\mid D_K \mid},$$

where D_K is the discriminant of K.

16. The *Cohen-Lenstra heuristics* [CoLe84] predict that if p is an odd prime, then p divides the class number of a certain fraction of imaginary quadratic fields. This fraction is

$$1 - \textstyle\prod_{m=1}^{\infty}(1 - p^m).$$

For $p = 3$, this is $0.43987\ldots$. For real quadratic fields, the predicted fraction is

$$1 - \textstyle\prod_{m=2}^{\infty}(1 - p^m).$$

For $p = 3$, this is $0.15981\ldots$. Both of these predictions agree well with computed data.

Examples:

1. If $K = \mathcal{Q}(\sqrt{-d})$ is an imaginary quadratic field, $r_1 = 0$ and $r_2 = 1$. Therefore, $r_1 + r_2 - 1 = 0$, so the group of units consists of only the roots of unity in K.

2. If $K = \mathcal{Q}(\sqrt{d})$ is a real quadratic field, $r_1 = 2$ and $r_2 = 0$. Therefore, $r_1 + r_2 - 1 = 1$, so the group of units is the direct sum of ±1 and an infinite cyclic group. The generator $\epsilon_0 > 1$ for this infinite cyclic group is called the *fundamental unit* of K.

3. Let a be an integer such that $a^2 + 3a + 9$ is square free. Let ϵ_1 and ϵ_2 be two of the roots of $X^2 - aX - (a+3)X - 1$. Then the group of units of the ring of algebraic integers in $\mathcal{Q}(\epsilon_1)$ is the direct sum of ±1 and the rank 2 free abelian group generated by ϵ_1 and ϵ_2. The fields of this form are known as the *simplest cubic fields*.

4. The ring of algebraic integers in $\mathcal{Q}(\sqrt{-5})$ is the set of numbers of the form $a + b\sqrt{-5}$, where a, b are integers. The ideal I generated by 2 and $1+\sqrt{-5}$ and the ideal J generated by 3 and $1 - \sqrt{-5}$ are not principal. Let $x = (1 - \sqrt{-5})/2$. Then $xI = J$, so I and J are in the same ideal class. The product IJ is by definition the ideal generated by the products of the generators of I and J, so it is the ideal generated by 6, $2 - 2\sqrt{-5}$, $3 + 3\sqrt{-5}$, and 6. Since $6 - (2 - 2\sqrt{-5}) - (3 + \sqrt{-5}) = 1 - \sqrt{-5}$ is in IJ, and all of these generators of IJ are multiples of $1 - \sqrt{-5}$, we find that IJ is the principal ideal generated by $1 - \sqrt{-5}$.

5. Let $K = \mathcal{Q}(\sqrt{-5})$. In the definition of D_K, take $\beta_1 = 1$ and $\beta_2 = \sqrt{-5}$. Then the matrix (a_{ij}) is

$$\begin{pmatrix} 2 & 0 \\ 0 & -10 \end{pmatrix},$$

which has determinant $D_K = -20$. The Minkowski bound is $4\sqrt{5}/\pi < 3$, so each ideal class contains an ideal of norm 1 or 2. Only the full ring of algebraic integers has norm 1, and the ideal I in the previous example is the only ideal of norm 2, so there are only two ideal classes. Therefore, the class number is 2.

6. Suppose we want to find all integer solutions of $x^2 + 1 = y^3$. Factor the left side as $(x + i)(x - i)$. It can be shown that $x + i$ and $x - i$ are relatively prime in $\mathcal{Z}[i]$, which has the unique factorization property. Since their product is a cube, each factor is a unit times a cube in $\mathcal{Z}[i]$. In particular, $x + i = (a + bi)^3$. The imaginary parts yield $1 = b(3a^2 - b^2)$, which implies that $b = \pm 1 = (3a^2 - b^2)$. This yields $a = 0$, hence $x = 0$. The only integer solution to $x^2 + 1 = y^3$ is therefore $(x, y) = (0, 1)$.

7. Suppose we want to find all solutions of $x^2 + 13 = y^3$. Factor the left side as $(x + \sqrt{-13})(x - \sqrt{-13})$. It can be shown that the ideals $I_1 = (x + \sqrt{-13})\mathcal{Z}[\sqrt{-13}]$ and $I_2 = (x - \sqrt{-13})\mathcal{Z}[\sqrt{-13}]$ are relatively prime, in the sense that they have no common prime ideal factors. The product $I_1 I_2$ equals the cube of the ideal $yZ[\sqrt{-13}]$. Unique factorization into prime ideals implies that both I_1 and I_2 must be cubes of ideals. Therefore, $J^3 = I_1$ for some ideal J of $\mathcal{Z}[\sqrt{-13}]$. But I_1 is a principal ideal, so J has order 1 or 3 in the ideal class group. The class number of $\mathcal{Q}(\sqrt{-13})$ is 2, so J^2 must also be principal. It follows that J is principal: $J = (a+b\sqrt{-13})\mathcal{Z}[\sqrt{-13}]$. Since $J^3 = I_1$, and the units of $\mathcal{Z}[\sqrt{-13}]$ are ±1, which are cubes, we must have $(a + b\sqrt{-13})^3 = x + \sqrt{-13}$. The coefficients of $\sqrt{-13}$ yield $1 = b(3a^2 - 13b^2)$, so $b = \pm 1 = 3a^2 - 13b^2$. This yields $a = \pm 4$, and then $x = \pm 70$, $y = 17$.

8. Let ω be a primitive cube root of unity. Let $\pi_1 = -3\omega - 1$ and $\pi_2 = -6\omega - 1$. Then $\pi_1 \equiv \pi_2 \equiv 2 \pmod{3}$. Since $N(\pi_2) = 31$, the cubic residue symbol is

$$\left(\frac{\pi_1}{\pi_2}\right)_3 \equiv \pi_1^{(31-1)/3} = -3725 - 18357\omega = 1 + (-6\omega - 1)(2952 - 129\omega) \equiv 1 \pmod{\pi_2}.$$

Since $\pi_2 = 1 + 2\pi_1 \equiv 1 \pmod{\pi_1}$, the cubic residue symbol is $\left(\frac{\pi_2}{\pi_1}\right)_3 = 1$.

9. In Example 8, cubic reciprocity plus the fact that $\pi_2 \equiv 1 \pmod{\pi_1}$ could be used to calculate $\left(\frac{\pi_1}{\pi_2}\right)_3$:

$$\left(\frac{\pi_1}{\pi_2}\right)_3 = \left(\frac{\pi_2}{\pi_1}\right)_3 = \left(\frac{1}{\pi_1}\right)_3 = 1.$$

This implies that π_1 is congruent to a cube mod π_2. A calculation yields $(12 + \omega)^3 \equiv \pi_1 \pmod{\pi_2}$.

4.10.5 PROPERTIES OF NUMBER FIELDS

Definitions:

The ring of algebraic integers in a number field is called ***monogenic*** if the ring is of the form

$$\mathcal{Z}[\alpha] = \{a_0 + a_1\alpha + a_2\alpha^2 + \cdots + a_m\alpha^m \mid m \geq 0,\ a_i \in \mathcal{Z} \text{ for } 0 \leq i \leq m\}.$$

Let p be a prime number and let K be a number field of degree n over $\mathcal{Q}$. Let $\mathcal{O}_K$ be the ring of algebraic integers in K. Factor the ideal $p\mathcal{O}_K$ into prime ideals in $\mathcal{O}_K$ as $P_1^{e_1}P_2^{e_2}\cdots P_g^{e_g}$, where $P_1, \ldots, P_g$ are distinct prime ideals of $\mathcal{O}_K$ and $e_1, \ldots, e_g$ are positive integers. If some $e_i > 1$ then p ***ramifies*** in K. If $g = n$ then p is said to ***split completely*** in K. If $g = 1$ and $e_1 = 1$, then p is ***inert*** in K.

The ***Dedekind zeta function*** of a number field K is defined to be

$$\zeta_K(s) = \sum_I N(I)^{-s},$$

where s is a complex number with $\mathcal{R}(s) > 1$ and the sum is over the nonzero ideals I of $\mathcal{O}_K$.

Facts:

1. A prime number p ramifies in a number field K if and only if p divides the discriminant D_K.

2. If $K \neq \mathcal{Q}$, then $|D_K| > 1$, so there is always at least one prime number that ramifies in K.

3. Let K be a number field and suppose its ring of integers is $\mathcal{Z}[\alpha]$. Let $f(X)$ be the minimal polynomial of α. Let p be a prime and suppose $f(X) \equiv h_1(X)^{e_1}h_2(X)^{e_2}\cdots h_g(X)^{e_g} \pmod{p}$ is the factorization of $f(X)$ mod p into monic polynomials that are distinct mod p and irreducible mod p. Then the ideal generated by p factors into prime ideals as $P_1^{e_1}P_2^{e_2}\cdots P_g^{e_g}$ in the ring of integers of K. The prime ideal P_i is generated by p and $h_i(\alpha)$.

4. The ring of algebraic integers in $\mathcal{Q}(\omega, \sqrt[3]{2})$, where ω is a primitive cube root of unity, is $\mathcal{Z}[\alpha]$, where $\alpha = (1 - \sqrt[3]{2} + w\sqrt[3]{4})/(1 - w)$.

5. Let ω be a primitive cube root of unity. The ring of algebraic integers of the field $\mathcal{Q}(\omega, \sqrt[3]{d})$ is not monogenic for any cubefree integers $d \neq \pm 2, \pm 4$. (See [Ch02].)

6. Let K be a Galois extension of $\mathcal{Q}$ of odd prime degree p over $\mathcal{Q}$. If $2p+1$ is composite, then the ring of algebraic integers in K is not monogenic. If $2p + 1 = \ell$ is prime, then the ring is monogenic if and only if $K = \mathcal{Q}(\cos(2\pi/\ell))$, in which case the ring is $\mathcal{Z}[2\cos(2\pi/\ell)]$. (See [Gr86].)

7. The *number field sieve* is a method that uses algebraic numbers to produce relations $x^2 \equiv y^2 \pmod{n}$ in integers. It is the basis for a very powerful factorization algorithm that has been used to factor integers of around 200 decimal digits. (See §4.5.1.)

8. The Dedekind zeta function of a number field, although defined initially only for $\mathcal{R}(s) > 1$, has a natural extension to a function analytic in the whole complex plane, except for a simple pole at 1.

9. The *Generalized Riemann Hypothesis* predicts that each zero of the Dedekind zeta function of a number field with real part between 0 and 1 must have real part equal to 1/2.

10. The Generalized Riemann Hypothesis implies the truth of Artin's conjecture (see §4.7.1) that every integer other than -1 and perfect squares is a primitive root for infinitely many primes.

Examples:

1. If $p \equiv 1 \pmod 4$, then p can be written as a sum of two squares: $p = a^2 + b^2$. Therefore, $p = (a + bi)(a - bi)$ in $\mathcal{Q}(i)$, which means that p splits completely in $\mathcal{Q}(i)$. If $p \equiv 3 \pmod 4$, then $p\mathcal{Z}[i]$ is a prime ideal, so p is inert. The relation $2 = -i(1 + i)^2$ written in terms of ideals becomes $(2) = (1 + i)^2$, so 2 ramifies.

2. The polynomial $X^2 + 5$ factors mod 3 as $(X + 1)(X + 2)$. Therefore (Fact 3), the ideal generated by 3 in $\mathcal{Z}[\sqrt{-5}]$ factors as P_1P_2, where P_1 is generated by $1 + \sqrt{-5}$ and 3, and P_2 is generated by $2 + \sqrt{-5}$ and 3.

3. The polynomial $X^2 + 5$ is irreducible mod 11. Therefore (Fact 3), the ideal generated by 11 in $\mathcal{Z}[\sqrt{-5}]$ is a prime ideal.

4. The polynomial $X^2 + 5$ factors mod 2 as $(X + 1)^2$. Therefore (Fact 3), the ideal generated by 2 in $\mathcal{Z}[\sqrt{-5}]$ factors as P^2, where P is the ideal generated by 2 and $1+\sqrt{-5}$.

4.10.6 CYCLOTOMIC FIELDS

Definitions:

The nth ***cyclotomic field*** is the field obtained by adjoining a primitive nth root of unity to the field of rational numbers, that is, the field $\mathcal{Q}(\zeta)$, where $\zeta = e^{2\pi i/n}$.

A prime p is called ***regular*** if p does not divide the class number of the pth cyclotomic field. If p divides this class number, p is called ***irregular***.

Facts:

1. Cyclotomic fields arose in the work of Gauss on constructibility of regular polygons by compass and straightedge.

2. Cyclotomic fields also arose as a natural setting for generalizations of quadratic reciprocity. (See §4.10.4.)

3. Kummer developed much of the theory of cyclotomic fields in the mid-1800s.

4. The classical proof of Fermat's last theorem for regular primes by Kummer relied on his introduction of ideal numbers and ideal class groups to establish a replacement for the unique factorization property in cyclotomic fields. See Example 4.

5. Kummer's work superseded incorrect proofs of Lamé and Cauchy, who had incorrectly and implicitly assumed that the pth cyclotomic field always has unique factorization.

6. Extensions of Kummer's work led to much progress on Fermat's last theorem through the 1900s, even though the eventual proof of the theorem was by different techniques.

7. The nth cyclotomic field has degree $\phi(n)$ over $\mathcal{Q}$, where ϕ is Euler's function.

8. The ring of algebraic integers in the nth cyclotomic field is $\mathcal{Z}[\zeta] = \{a_0 + a_1\zeta + \cdots + a_{\phi(n)-1}\zeta^{\phi(n)-1} \mid a_i \in \mathcal{Z}\}$, where ζ is a primitive nth root of unity. Therefore, this ring is monogenic.

9. The *Kronecker-Weber theorem* says that if K is a number field such that $K/\mathcal{Q}$ is a Galois extension with abelian Galois group, then K is contained in a cyclotomic field.

10. Let $n \geq 3$ be an integer. The nth cyclotomic field contains the field $\mathcal{Q}(\cos(2\pi/n))$, and the class number h_n^+ of this latter field divides the class number h_n of the nth cyclotomic field.

11. The quotient $h_n^- = h_n/h_n^+$ can be computed fairly quickly. The computation of h_n^+ is difficult.

12. The largest prime p for which h_p^+ has been computed is $p = 151$ (and $h_{151}^+ = 1$).

13. *Vandiver's conjecture* predicts that if p is prime then p does not divide h_p^+. This has been verified for all $p < 163 \cdot 10^6$.

14. There are infinitely many irregular primes. It has not been proved that there are infinitely many regular primes. Heuristic models predict that about 61% $(= e^{-1/2})$ of primes are regular. This prediction agrees well with computational data.

15. Let p be prime. The numbers $\epsilon_a = \sin(2\pi a/p)/\sin(2\pi/p)$ for $2 \leq a \leq (p-1)/2$ are units of the ring of algebraic integers of the pth cyclotomic field. They, along with -1 and the pth roots of unity, generate a subgroup, called the *cyclotomic units*, of index h_p^+ in the group of units of the ring of algebraic integers of this field.

16. Preda Mihăilescu's proof of the Catalan conjecture (§4.8.4) relied heavily on properties of cyclotomic fields.

Examples:

1. Let p be an odd prime. The class number h_p of the pth cyclotomic field is 1 if and only if $p \leq 19$. The class number of the 23rd cyclotomic field is 3.

2. The class number of the 37th cyclotomic field is $h_{37} = 37$. This factors as $h_{37}^- = 37$ and $h_{37}^+ = 1$. The class number of the 59th cyclotomic field is 41241, which factors as $h_{59}^- = 41241 = 3 \cdot 59 \cdot 233$ and $h_{59}^+ = 1$. Both 37 and 59 are irregular primes.

3. The smallest prime p with $h_p^+ > 1$ is $p = 163$, for which $h_{163}^+ = 4$.

4. *First case of Fermat's last theorem for regular primes*: Suppose x, y, z are nonzero integers not divisible by the odd, regular prime p, and $x^p + y^p = z^p$. Let ζ be a primitive pth root of unity. Then $\prod_{j=1}^{p}(x + \zeta^j y) = z^p$. If $\gcd(x, y, z) = 1$ then the factors $x + \zeta^j y$ are pairwise relatively prime. Since their product is a pth power, the ideal generated by each factor is the pth power of an ideal: $(x + \zeta^j y) = I_j^p$. If the class number of the pth cyclotomic field is not a multiple of p, then this implies that I_j must be principal, so $x + \zeta^j y$ is a unit times the pth power of an element of the field. This is the same as can be obtained when there is unique factorization in the pth cyclotomic field. The remainder of the argument is fairly straightforward. See [Wa97].

4.11 ELLIPTIC CURVES

Elliptic curves have been studied since the time of Diophantus and continue to be a very active area of research. The most important fact is that the points on an elliptic curve have a group structure. Elliptic curves arise as diophantine equations, and they played a crucial role in the proof of Fermat's last theorem. Elliptic curves over finite fields are a basic tool in cryptography, mostly because of the difficulty of the Discrete Log Problem.

4.11.1 BASIC CONCEPTS

Definitions:

If F is a field of characteristic not 2 or 3, an ***elliptic curve E defined over F*** is a curve that can be given by the ***Weierstrass equation***

$$y^2 = x^3 + Ax + B,$$

where $A, B \in F$. It is required that the cubic polynomial $x^3 + Ax + B$ have no repeated roots, which is equivalent to $4A^3 + 27B^2 \neq 0$.

If K is a field containing F, then we denote

$$E(K) = \{(x, y) \mid (x, y) \text{ lies on } E \text{ and } x, y \in K\} \cup \{\infty\},$$

where ∞ is the point at infinity. (See Fact 10.)

If E is given by $y^2 = x^3 + Ax + B$, then the ***j-invariant*** is defined as

$$j(E) = (1728)4A^3/(4A^3 + 27B^2).$$

Given points P and Q on an elliptic curve E in Weierstrass form, the ***group law*** (or ***addition law***) is defined as follows. Draw the line through P and Q (the tangent line to E if $P = Q$). This line intersects E at a third point R' (if the line is vertical, $R' = \infty$; see Facts 10 and 11). Reflect R' across the x-axis to get a point R. This operation is denoted $P + Q = R$ (it is not simply coordinate addition).

If n is a positive integer, then the ***multiple n of point p*** is the sum of n copies of P: i.e., $nP = P + P + \cdots + P$.

A ***torsion point*** is a point P on an elliptic curve E such that $nP = \infty$ for some integer $n > 0$, where ∞ is the point at infinity (see Fact 10).

Facts:

1. Comprehensive coverage of elliptic curves can be found in [Si09], [SiTa15], and [Wa08].

2. Although elliptic curves can be defined over arbitrary fields, the most important examples are over finite fields, the rational numbers, and the complex numbers.

3. Elliptic curves are not ellipses. They received their name because of their close relation with elliptic integrals, which occur in many physical problems, including finding the arc length of an ellipse.

4. The addition of points satisfies the associative law: $(P + Q) + R = P + (Q + R)$.

5. If K is a field containing the coefficients of E, the addition law makes $E(K)$ into an abelian group, where the point at infinity is the identity element.

6. The inverse of a point $P = (x, y)$ is $-P = (x, -y)$. Points can be subtracted: $Q - P = Q + (-P)$.

7. *Addition of points*: Let E be an elliptic curve defined by $y^2 = x^3 + Ax + B$. Let $P_1 = (x_1, y_1)$ and $P_2 = (x_2, y_2)$ be points on E with $P_1, P_2 \neq \infty$. Let $P_1 + P_2 = P_3 = (x_3, y_3)$.

- If $x_1 \neq x_2$, then

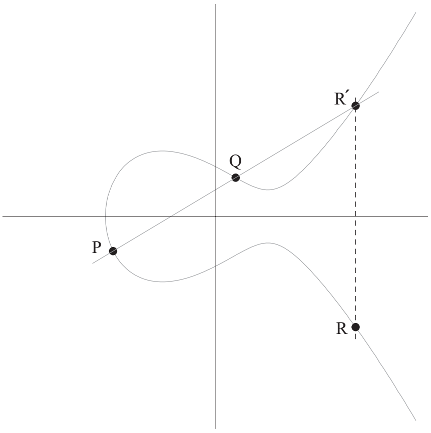
$$x_3 = m^2 - x_1 - x_2, \qquad y_3 = m(x_1 - x_3) - y_1, \qquad \text{where } m = \tfrac{y_2 - y_1}{x_2 - x_1}.$$

- If $x_1 = x_2$ but $y_1 \neq y_2$, then $P_1 + P_2 = \infty$.
- If $P_1 = P_2$ and $y_1 \neq 0$, then

$$x_3 = m^2 - 2x_1, \qquad y_3 = m(x_1 - x_3) - y_1, \qquad \text{where } m = \tfrac{3x_1^2 + A}{2y_1}.$$

- If $P_1 = P_2$ and $y_1 = 0$, then $P_1 + P_2 = \infty$.
- $P_1 + \infty = P_1$.

8. The following figure gives a picture of how addition works for elliptic curves over the real numbers. For most fields, this picture cannot be drawn, but it is helpful for geometric intuition.



9. A curve $y^2 = x^3 + Ax + B$ can be put into homogeneous form $y^2z = x^3 + Axz^2 + Bz^3$ and the points on the curve are points $(x : y : z)$ in projective space. If $z \neq 0$, such a point can be rescaled to $(x/z : y/z : 1)$, which is a point on the original nonhomogeneous curve.

10. In homogeneous coordinates, the curve in projective space contains the point $(x : y : z) = (0 : 1 : 0)$, which is called the *point at infinity*. In most situations, it is easiest to regard the point at infinity as a formal symbol ∞ that acts as the identity of the group law. The point at infinity is usually denoted ∞ or $\mathcal{O}$.

11. Vertical lines ($x =$ constant) in the plane extend in projective space to contain the point at infinity.

12. When the characteristic of the field is 2 or 3, the *generalized Weierstrass form* is used:

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6,$$

with $a_1, a_2, a_3, a_4, a_6 \in F$. The reflection across the x-axis in the group law is replaced by the map $(x, y) \mapsto (x, -y - a_1x - a_3)$. See [Si09].

13. When the characteristic of the field is not 2 or 3, there are situations where the generalized Weierstrass form $y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$ is useful, but a change of variables can be used to put the curve into Weierstrass form.

14. Elliptic curves played a crucial role in the proof of Fermat's last theorem (§4.8.3). Suppose $a^n + b^n = c^n$, where a, b, c, n are positive integers and $n \geq 3$. Form the elliptic curve

$$y^2 = x(x - a^n)(x + b^n).$$

The fact that the cubic polynomial has discriminant $(abc)^{2n}$, which is a $2n$th power, forces the elliptic curve to have properties so restrictive that it can be shown that such a curve cannot exist. Therefore, a, b, c cannot exist.

15. In the 1980s, Hendrik Lenstra developed a method for factorization of integers using elliptic curves. It is similar to the Pollard $p-1$ method (see §4.5.1), but has the advantage that it can use several elliptic curves in parallel. If a set of curves does not produce the factorization, another set can be used, an aspect that has no analogue for the Pollard $p - 1$ algorithm. The method is effective for factoring integers of around 50 decimal digits.

16. Shafi Goldwasser and Joe Kilian invented a primality test based on elliptic curves. It was refined by Oliver Atkin and François Morain and has been used to prove the primality of integers with more than 20,000 decimal digits. (See §4.4.4, Fact 18.)

17. Suppose we have a curve defined over a field of characteristic not 2 by an equation $v^2 = au^4 + bu^3 + cu^2 + du + e$ and suppose we have a point (p, q) lying on the curve. There is a change of variables that transforms the equation to Weierstrass form. See [Co92].

18. A nonsingular plane cubic curve can be changed to a curve in Weierstrass form; a sketch of the procedure is given in [SiTa15]. See Example 4 for a simple example.

19. Let E be an elliptic curve over F, let n be a positive integer not divisible by the characteristic of F, and let $E[n]$ be the set of points $P \in E(\overline{F})$ (where $\overline{F}$ is the algebraic closure of F) that satisfy $nP = \infty$. Then $E[n] \simeq \mathcal{Z}/n\mathcal{Z} \oplus \mathcal{Z}/n\mathcal{Z}$.

20. Let E be defined over a field F of characteristic $p > 0$, let $m > 0$, and let $E[p^m]$ be the set of points $P \in E(\overline{F})$ that satisfy $p^mP = \infty$. Then $E[p^m] \simeq$ either $\mathcal{Z}/p^m\mathcal{Z}$ or 0. The second case happens if and only if E is supersingular (see §4.11.3).

21. Let E be an elliptic curve over F, let n be a positive integer not divisible by the characteristic of F, and let $E(F)[n]$ be the set of points $P \in E(F)$ that satisfy $nP = \infty$. If $E(F)[n] \simeq \mathcal{Z}/n\mathcal{Z} \oplus \mathcal{Z}/n\mathcal{Z}$, then F contains the nth roots of unity. When $F = GF(q)$, this means that $n \mid q - 1$.

Examples:

1. The elliptic curve $y^2 = x^3 + 73$ contains the points $(2, 9)$ and $(3, 10)$. The line through these two points is $y = x + 7$, which intersects the elliptic curve in $(2, 9)$, $(3, 10)$, and $(-4, 3)$. The reflection across the x-axis of the third point is $(-4, -3)$, so $(2, 9) + (3, 10) = (-4, -3)$.

2. The line $y = (2/3)(x - 2) + 9$ is tangent to the elliptic curve $y^2 = x^3 + 73$ at the point $(2, 9)$. The line also intersects the curve at $(-32/9,\ 143/27)$. The reflection across the x-axis is $(-32/9,\ -143/27)$, so $2(2, 9) = (2, 9) + (2, 9) = (-32/9,\ -143/27)$.

3. The point $P=(2,3)$ is a torsion point on the elliptic curve $y^2=x^3+1$. The multiples of this point are

$$2P=(0,1),\quad 3P=(-1,0),\quad 4P=(0,-1),\quad 5P=(2,-3),\quad 6P=\infty.$$

4. The change of variables $x=12c/(a+b)$, $y=36(a-b)/(a+b)$ changes the elliptic curve $y^2=x^3-432$ into the Fermat equation of exponent 3, namely, $a^3+b^3=c^3$.

5. The *cannonball problem*, which goes back at least to Edouard Lucas in 1875, asks if there is a set of cannonballs that can be put into a square pyramid and also can be arranged in a square array. If the square pyramid has x layers and the square array is $y\times y$, the problem asks for integer solutions to $y^2=x(x+1)(2x+1)/6$, an equation that can be transformed into Weierstrass form $y_1^2=x_1^2-36x_1$ with the change of variables $x=(x_1-6)/12$, $y=y_1/72$. Besides the trivial solutions $x=0$ and $x=1$, the only other nonnegative integral solution is $x=24$, corresponding to 4,900 cannonballs.

6. The *congruent number problem* asks which positive integers occur as areas of right triangles with rational sides. Such an integer was called a *congruent number* by Fibonacci. The problem of finding congruent numbers appears in an Arab manuscript before 1000 CE. For example, 5 occurs as the area of the right triangle with sides 3/2, 20/3, 41/6.

7. Fermat used his method of infinite descent to show that 1 is not a congruent number.

8. Under the assumption of the truth of the conjecture of Birch and Swinnerton-Dyer (see §4.11.4, Fact 5) for the elliptic curve $y^2=x^3-n^2x$, Jerrold Tunnell gave a simple criterion for determining whether the integer n is a congruent number.

9. The congruent numbers less than 40 are 5, 6, 7, 13, 14, 15, 20, 21, 22, 23, 24, 28, 29, 30, 31, 34, 37, 38, 39.

10. Finding a rational right triangle of area n is equivalent to finding an x such that $x-n$, x, and $x+n$ are all squares of rational numbers.

11. Nathan Fine [Fi76] showed, implicitly using the theory of elliptic curves, that every positive rational occurs as the area of some triangle (not necessarily a right triangle) with rational sides.

12. Several applications of elliptic curves to recreational mathematics are given in [Ma16].

4.11.2 ISOMORPHISMS, ENDOMORPHISMS, AND ISOGENIES

Definitions:

Let E_1,E_2 be elliptic curves defined over F, where E_i is given by $y^2=x^3+A_ix+B_i$ for $i=1,2$. A map $\phi: E_1(\overline{F})\to E_2(\overline{F})$ is said to be ***given by rational functions*** (where $\overline{F}$ is the algebraic closure of F) if there are rational functions $f(x,y)$ and $g(x,y)$ such that $\phi(x,y)=(f(x,y),g(x,y))$.

A map given by rational functions is ***defined over a field*** K if the coefficients of the rational functions f and g can be chosen to be elements of K.

An ***endomorphism*** of an elliptic curve is a homomorphism, given by rational functions, from an elliptic curve to itself. The zero endomorphism maps every point to the point ∞.

An elliptic curve E has ***complex multiplication*** (***CM***) if there are endomorphisms of E that are not given by multiplication by an integer.

Let E_1, E_2 be elliptic curves defined over F. An ***isogeny*** is a homomorphism, given by rational functions, from $E_1(\overline{F})$ to $E_2(\overline{F})$, where $\overline{F}$ is the algebraic closure of F.

Two elliptic curves E_i, $i = 1, 2$, given in Weierstrass form by $y_i^2 = x_i^3 + A_i x_i + B_i$, for $i = 1, 2$, are ***isomorphic*** over a field K (containing all A_i, B_i) if there is a constant $u \in K$ such that the change of variables

$$x_2 = u^2 x_1, \quad y_2 = u^3 y_1$$

maps the points on E_1 with coordinates in the algebraic closure of K to those on E_2.

Two elliptic curves E_1 and E_2 defined over a field F are said to be ***twists*** of each other if they are isomorphic over the algebraic closure of F.

Facts:

1. If a map is given by rational functions f and g, as in the definitions, then $g^2 = f^3 + A_2 f + B_2$ for all $x, y \in \overline{F}$ satisfying $y^2 = x^3 + A_1 x + B_1$.

2. Let E be an elliptic curve and let n be an integer. The map $P \mapsto nP$ is given by rational functions (for $n = 2$, see the addition formula (§4.11.1) applied to the case $P_1 = P_2$).

3. Two elliptic curves defined over a field F are isomorphic over the algebraic closure of F if and only if they have the same j-invariant.

4. Let E be defined over F. The endomorphisms of E defined over the algebraic closure of F form a ring (under addition and composition of functions).

5. If the characteristic of F is 0, this ring of endomorphisms is isomorphic either to $\mathcal{Z}$ or to a subring of the ring of algebraic integers (see §4.10.2) in an imaginary quadratic field.

6. If F is a finite field of characteristic p, this ring of endomorphisms is isomorphic either to a subring of the ring of algebraic integers (see §4.10.2) in an imaginary quadratic field or to a noncommutative ring (in technical terms: a maximal order in a quaternion algebra over $\mathcal{Q}$ that is ramified only at p and ∞).

7. A noncommutative endomorphism ring occurs if and only if E is supersingular.

8. The most common situation where E_1 and E_2 are twists of each other is when E_i is defined by $y^2 = x^3 + A_i x + B_i$ and there is a nonzero $d \in F$ such that $A_2 = d^2 A_1$ and $B_2 = d^3 B_1$, in which case the isomorphism is given by $(x, y) \mapsto (dx, d^{3/2} y)$.

Examples:

1. The elliptic curves $y_1^2 = x_1^3 + 3x_1 + 7$ and $y_2^2 = x_2^3 + 12x_2 + 56$ are twists of each other. They both have the j-invariant 6912/53. The change of variables $x_2 = 2x_1$, $y_2 = 2^{3/2} y_1$ transforms one curve to the other.

2. Let E be the elliptic curve $y^2 = x^3 + x$ defined over $\mathcal{C}$. The map $\phi : (x, y) \mapsto (-x, iy)$ gives an endomorphism of E that is not multiplication by an integer, so E has complex multiplication. It is easy to see that ϕ^4 is the identity. The ring $\mathcal{Z}[i]$, with i corresponding to ϕ, is the endomorphism ring of E.

3. Let $E_1 : y_1^2 = x_1^3 + a x_1^2 + b x_1$ be an elliptic curve over a field of characteristic not 2. We require $b \neq 0$ and $a^2 - 4b \neq 0$ in order to have $4A^3 + 27B^2 \neq 0$ when the curve is changed to Weierstrass form. Let E_2 be the elliptic curve $y_2^2 = x_2^3 - 2ax_2^2 + (a^2 - 4b)x_2$. Define α by

$$(x_2, y_2) = \alpha(x_1, y_1) = \left(\tfrac{y_1^2}{x_1^2}, \tfrac{y_1(x_1^2-b)}{x_1^2}\right).$$

Then α is an isogeny from E_1 to E_2. The kernel of α is $\{\infty, (0,0)\}$.

4.11.3 ELLIPTIC CURVES OVER FINITE FIELDS

Definitions:

Given a point P on an elliptic curve and multiples nP and mP, where m, n are integers that are not revealed, the ***computational Diffie-Hellman problem*** is that of finding mnP.

Given two points P and Q on an elliptic curve such that $Q = nP$ for some integer n, the ***discrete logarithm problem*** is that of finding an integer k such that $Q = kP$.

If E is an elliptic curve defined over a finite field $GF(q)$, the ***Frobenius map*** ϕ_q maps a point (x, y) (with x, y in the algebraic closure of $GF(q)$) to the point (x^q, y^q).

A ***supersingular elliptic curve*** is an elliptic curve defined over a field F of characteristic p that has no points of order p with coordinates in the algebraic closure of F.

Let A, B, C, be groups, and let $*$ denote their group operations. A ***bilinear pairing*** is a map

$$A \times B \to C, \quad (a, b) \mapsto c = \langle a, b\rangle,$$

such that

$$\langle a_1 * a_2, b\rangle = \langle a_1, b\rangle * \langle a_2, b\rangle, \qquad \langle a, b_1 * b_2\rangle = \langle a, b_1\rangle * \langle a, b_2\rangle$$

for all $a, a_1, a_2 \in A$ and all $b, b_1, b_2 \in B$. Two common pairings are the Tate-Lichtenbaum pairing and the Weil pairing (see Fact 7).

Facts:

1. The set of points $E(GF(q))$ forms a finite group. It has the structure

$$\mathcal{Z}/m\mathcal{Z} \quad \text{or} \quad \mathcal{Z}/m\mathcal{Z} \times \mathcal{Z}/n\mathcal{Z}$$

for some integers m, n.

2. *Hasse's theorem*: Let E be an elliptic curve defined over $GF(q)$ and let N be the number of points on E with coordinates in $GF(q)$. Then

$$q + 1 - 2\sqrt{q} \le N \le q + 1 + 2\sqrt{q}.$$

3. Let E be an elliptic curve defined over $GF(q)$ and let $a = \#E(GF(q))$. Write

$$X^2 - aX + q = (X - \alpha)(X - \beta).$$

Then the number of points on E with coordinates in $GF(q^n)$ is

$$q^n + 1 - \alpha^n - \beta^n.$$

4. The Frobenius map ϕ_q of an elliptic curve E defined over $GF(q)$ is an endomorphism of E, and $\phi_q^2 - a\phi_q + q$ is the zero endomorphism, where $a = q + 1 - \#E(GF(q))$.

5. There is an efficient algorithm due to Schoof-Elkies-Atkin that counts the number of points on an elliptic curve over a finite field.

6. An elliptic curve over a finite field F of characteristic p is supersingular if and only if the order of $E(F)$ is congruent to 1 modulo p.

7. Let E be an elliptic curve defined over a finite field $F = GF(q)$ and let n be a positive integer such that $q-1$ is a multiple of n. Let $E[n]$ be the set of points P with coordinates in the algebraic closure of F such that $nP = \infty$. The *Tate-Lichtenbaum pairing* is a nondegenerate bilinear pairing

$$\tau_n : E[n] \times (E(F)/nE(F)) \to \mu_n,$$

where μ_n is the group of nth roots of unity in F. The *Weil pairing* is a nondegenerate bilinear pairing

$$e_n : E[n] \times E[n] \to \mu_n.$$

8. The Weil pairing and the Tate-Lichtenbaum pairing can be computed efficiently by Miller's algorithm [Mi04].

9. The Tate-Lichtenbaum pairing (and the Weil pairing) can be used to attack the discrete logarithm problem. Let E be defined over $GF(q)$. Suppose that P, Q are points of order ℓ on E and $kP = Q$. Let q^n be chosen so that $\ell \mid q^n - 1$ (the smallest such $n > 0$ is called the *embedding degree*). Choose a random point $R \in E(GF(q^n))$ and compute $\alpha = \tau_\ell(P, R)$ and $\beta = \tau_\ell(Q, R)$. Then $\beta = \alpha^k$, so we have a discrete logarithm problem in $GF(q^n)$. If n is small, it is easier to attack this discrete logarithm problem (for fields) than to use methods that work on arbitrary elliptic curves.

Examples:

1. Let E be the elliptic curve $y^2 = x^3 + 4x + 1$ defined over $GF(5)$. The points in $E(GF(5))$ are $\infty, (0,1), (0,4), (1,1), (1,4), (3,0), (4,1), (4,4)$. The addition law yields $(0,1) + (1,4) = (3,0)$ and $2(1,1) = (4,1)$. There are eight points, so $a = 5+1-8 = -2$. The polynomial $X^2 + 2X + 5$ factors as $(X + 1 - 2i)(X + 1 + 2i)$. Therefore (see Fact 3), the number of points in $E(GF(5^n))$ is $5^n + 1 - (-1+2i)^n - (-1-2i)^n$. The group $E(GF(5))$ is cyclic of order 8.

2. Let E be the elliptic curve $y^2 = x^3 + 4x + 1$ defined over $GF(5)$. An example of the discrete logarithm problem is to find k such that $k(0,1) = (1,1)$. The answer in this case is $k = 5$.

3. There is a list of 15 elliptic curves recommended by NIST (see [FIPS186-3]).

4. The elliptic curve E defined by $y^2 \equiv x^3 + 1 \pmod 5$ has six points with coordinates in $\mathcal{Z}/5\mathcal{Z}$. Therefore, it is supersingular. Let ω be a primitive cube root of unity in the algebraic closure of $GF(5)$. Then $\alpha : (x, y) \mapsto (\omega x, y)$ is an endomorphism of E. Let $\phi = \phi_5$ be the Frobenius map. Then $\phi\alpha(x, y) = (\omega^2 x^5, y^5)$, but $\alpha\phi(x, y) = (\omega x^5, y^5)$. Therefore, the ring of endomorphisms of E is noncommutative.

4.11.4 ELLIPTIC CURVES OVER $\mathcal{Q}$

Definition:

Let E be an elliptic curve given in generalized Weierstrass form with integer coefficients. For each prime p, look at the equation for E modulo p. For all primes not in a finite set S_E, this yields a nonsingular curve modulo p. Let $a_p = p + 1 - \#E(GF(p))$. The ***L*-series** for E is

$$L(E, s) = \prod_{p \in S_E} (L_p(s))^{-1} \prod_{p \notin S_E} \left(1 - a_p p^{-s} + p^{1-2s}\right)^{-1} = \sum_{n=1}^{\infty} a_n n^{-s},$$

where the finitely many factors $L_p(s)$ depend on the properties of E modulo p, and where s is a complex variable with $\mathcal{R}(s) > 3/2$.

Facts:

1. *Mordell-Weil theorem*: If F is a finite extension of $\mathcal{Q}$ and E is defined over F, then $E(F)$ is a finitely generated abelian group, which means that $E(F) \simeq \mathcal{Z}^r \oplus T$, where T is a finite group. The integer r is called the *Mordell-Weil rank* of $E(F)$.

2. In 2006, Noam Elkies discovered an elliptic curve defined over $\mathcal{Q}$ whose Mordell-Weil rank is at least 28. It has been conjectured that there are elliptic curves of arbitrarily large Mordell-Weil rank. On the other hand, Andrew Granville and Bjorn Poonen have each produced heuristic arguments that indicate that there should be an upper bound on the rank of elliptic curves.

3. Manjul Barghava and Arul Shankar have proved that the average rank of elliptic curves defined over $\mathcal{Q}$ is at most 7/6.

4. If E is an elliptic curve defined over $\mathcal{Q}$, the L-series of E has a continuation to an analytic function defined in the whole complex plane. It has a functional equation relating $L(E, s)$ and $L(E, 2 - s)$. This was conjectured by Taniyama, Shimura, and Weil and was proved by Wiles, Taylor, Breuil, Conrad, and Diamond.

5. *Conjecture of Birch and Swinnerton-Dyer*: Let E be defined over $\mathcal{Q}$. The *analytic rank* of E is the order of vanishing of $L(E, s)$ at $s = 1$ (that is, the degree of the first nonzero term in the Taylor series at $s = 1$). It is conjectured that the analytic rank of E equals the Mordell-Weil rank of $E(\mathcal{Q})$. This is known to be true when the analytic rank is 0 or 1 by work of Victor Kolyvagin and others.

6. *Lutz-Nagell theorem*: Let E be defined over $\mathcal{Q}$ by the equation $y^2 = x^3 + Ax + B$ with $A, B \in \mathcal{Z}$. Let $\infty \neq (x, y) \in E(\mathcal{Q})$ be a torsion point. Then $x, y \in \mathcal{Z}$, and either $y = 0$ or $y^2 \mid 4A^3 + 27B^2$.

7. *Mazur's theorem*: Let E be defined over $\mathcal{Q}$. The torsion subgroup of $E(\mathcal{Q})$ has one of the following forms:

$$\mathcal{Z}/n\mathcal{Z} \text{ for } 1 \leq n \leq 10 \text{ or } n = 12; \quad \mathcal{Z}/n\mathcal{Z} \times \mathcal{Z}/2\mathcal{Z} \text{ for } 1 \leq n \leq 4.$$

Examples:

1. Let E be defined by $y^2 = x^3 + 1$. Then $4A^3 + 27B^2 = 27$. Suppose (x, y) is a torsion point with $y \neq 0$. The Lutz-Nagell theorem says that $y^2 \mid 27$, so $y = \pm 1$ or ± 3. This yields the points $(0, \pm 1)$ and $(2, \pm 3)$. It can be checked that $3(0, -1) = 3(0, 1) = \infty$ and $6(2, 3) = 6(2, -3) = \infty$, so these are torsion points. The only point with $y = 0$ is $(-1, 0)$. Therefore, the torsion subgroup of $E(\mathcal{Q})$ has order 6 and is

$$\{\infty, (-1, 0), (0, -1), (0, 1), (2, -3), (2, 3)\}.$$

2. Let E be defined by $y^2 = x^3 - 16x + 16$. The Lutz-Nagell theorem (Fact 6) implies that if (x, y) is a torsion point with $y \neq 0$, then $y^2 \mid 2^8 \cdot 37$, so $y = \pm 2^j$ with $0 \leq j \leq 4$. These do not yield torsion points, and neither does $y = 0$, so the torsion subgroup of $E(\mathcal{Q})$ is trivial. Therefore, $E(\mathcal{Q}) \simeq \mathcal{Z}^r$ for some r. In fact, $r = 1$ and the points with rational coordinates are the multiples of the point $P = (0, 4)$. The first few multiples of P are

$$2P = (4, 4), \quad 3P = (-4, -4), \quad 4P = (8, -20), \quad 5P = (1, -1),$$
$$6P = (24, 116), \quad 7P = (-20/9, 172/27), \quad 8P = (84/25, -52/125).$$

4.11.5 ELLIPTIC CURVES OVER $\mathcal{C}$

Definition:

Given a lattice $L = \mathcal{Z}\omega_1 + \mathcal{Z}\omega_2$ in $\mathcal{C}$, the ***Weierstrass $\wp$-function*** is given by

$$\wp(z) = \wp(z; L) = \tfrac{1}{z^2} + \sum_{\substack{\omega \in L \\ \omega \neq 0}} \left(\tfrac{1}{(z-\omega)^2} - \tfrac{1}{\omega^2} \right).$$

Facts:

1. If E is defined over the complex numbers $\mathcal{C}$, then $E(\mathcal{C})$ is isomorphic to $\mathcal{C}/L$, where L is a lattice in $\mathcal{C}$ (that is, L is an additive subgroup of $\mathcal{C}$ of the form $\mathcal{Z}\omega_1 + \mathcal{Z}\omega_2$, where ω_1, ω_2 are complex numbers that are linearly independent over the real numbers).

2. The Weierstrass $\wp$-function is meromorphic in $\mathcal{C}$, has a double pole at each $\omega \in L$, and is doubly periodic: $\wp(z + \omega_1) = \wp(z + \omega_2) = \wp(z)$ for all $z \in \mathcal{C}$.

3. Given a lattice L in $\mathcal{C}$, there are constants g_2, g_3 such that the associated Weierstrass $\wp$-function satisfies

$$\wp'(z)^2 = 4\wp(z)^3 - g_2\wp(z) - g_3$$

for all $z \in \mathcal{C}$. This means that there is a map

$$z \mapsto (\wp(z), \tfrac{1}{2}\wp'(z))$$

from $\mathcal{C}/L$ to $E(\mathcal{C})$, where E is the elliptic curve defined over $\mathcal{C}$ by $y^2 = x^3 - (g_2/4)x - (g_3/4)$. This is an isomorphism of groups.

4. When an elliptic curve with complex multiplication is represented over the complex numbers as $\mathcal{C}/L$ for a lattice L, then the complex multiplication is given by multiplication by (nonreal) complex numbers α such that $\alpha L \subseteq L$.

ALGEBRAIC STRUCTURES

John G. Michaels

INTRODUCTION

Many of the most common mathematical systems, including the integers, the rational numbers, and the real numbers, have an underlying algebraic structure. This chapter examines the structure and properties of various types of algebraic objects. These objects arise in a variety of settings and occur in many different applications, including counting techniques, coding theory, information theory, engineering, and circuit design.

GLOSSARY

abelian group: a group in which $a \star b = b \star a$ for all a, b in the group.

absorption laws: in a lattice $a \vee (a \wedge b) = a$ and $a \wedge (a \vee b) = a$.

algebraic element (over a field): given a field F, an element $\alpha \in K$ (extension of F) such that there exists $p(x) \in F[x]$ $(p(x) \neq 0)$ such that $p(\alpha) = 0$. Otherwise α is ***transcendental*** over F.

algebraic extension (of a field): given a field F, a field K such that F is a subfield of K and all elements of K are algebraic over F.

algebraic integer: an algebraic number that is a zero of a monic polynomial with coefficients in $\mathcal{Z}$.

algebraic number: a complex number that is algebraic over $\mathcal{Q}$.

algebraic structure: $(S, \star_1, \star_2, \ldots, \star_n)$ where S is a nonempty set and $\star_1, \ldots, \star_n$ are binary or monadic operations defined on S.

alternating group (on n elements): the subgroup A_n of all even permutations in S_n.

associative property: the property of a binary operator $\star$ that $(a \star b) \star c = a \star (b \star c)$.

atom: an element a in a bounded lattice such that $0 < a$ and there is no element b such that $0 < b < a$.

automorphism: an isomorphism of an algebraic structure onto itself.

automorphism φ fixes set S elementwise: $\varphi(a) = a$ for all $a \in S$.

binary operation (on a set S): a function $\star\colon S \times S \to S$.

Boolean algebra: a bounded, distributive, complemented lattice. Equivalent definition: $(B, +, \cdot, ', 0, 1)$ where B is a set with two binary operations, $+$ (addition) and $\cdot$ (multiplication), one monadic operation, $'$ (complement), and two distinct elements, 0 and 1, that satisfy the commutative laws ($a + b = b + a$, $a \cdot b = b \cdot a$), distributive laws ($a \cdot (b + c) = (a \cdot b) + (a \cdot c)$, $a + (b \cdot c) = (a + b) \cdot (a + c)$), identity laws ($a + 0 = a$, $a \cdot 1 = a$), and complement laws ($a + a' = 1$, $a \cdot a' = 0$).

Boolean function of degree n: a function $f\colon \{0,1\}^n = \{0,1\} \times \cdots \times \{0,1\} \to \{0,1\}$.

bounded lattice: a lattice having elements 0 (***lower bound***) and 1 (***upper bound***) such that $0 \leq a$ and $a \leq 1$ for all a.

cancellation properties: if $ab = ac$ and $a \neq 0$, then $b = c$ (***left cancellation property***); if $ba = ca$ and $a \neq 0$, then $b = c$ (***right cancellation property***).

characteristic (of a field): the smallest positive integer n such that $1+1+\cdots+1 = 0$ (n summands). If no such n exists, the field has characteristic 0 (or characteristic ∞).

closure property: a set S is closed under an operation $\star$ if the range of $\star$ is a subset of S.

commutative property: the property of an operation $\star$ that $a \star b = b \star a$.

commutative ring: a ring in which multiplication is commutative.

complemented lattice: a bounded lattice such that for each element a there is an element b such that $a \vee b = 1$ and $a \wedge b = 0$.

conjunctive normal form (***CNF***) (of a Boolean function): a Boolean function written as a product of maxterms.

coset: For a subgroup H of group G and $a \in G$, a ***left coset*** is $aH = \{ah \mid h \in H\}$; a ***right coset*** is $Ha = \{\, ha \mid h \in H \,\}$.

cycle of length n: a permutation on a set S that moves elements only in a single orbit of size n.

cyclic group: a group G with an element $a \in G$ such that $G = \{\, a^n \mid n \in \mathcal{Z} \,\}$.

cyclic subgroup (generated by a): $\{\, a^n \mid n \in \mathcal{Z} \,\} = \{\ldots, a^{-2}, a^{-1}, e, a, a^2, \ldots\}$, often written (a), $\langle a \rangle$, or $[a]$. The element a is a ***generator*** of the subgroup.

degree (of field K over field F): $[K\colon F]$ = the dimension of K as a vector space over F.

degree (of a permutation group): the size of the set on which the permutations are defined.

dihedral group: the group D_n of symmetries (rotations and reflections) of a regular n-gon.

disjunctive normal form (***DNF***) (of a Boolean function): a Boolean function written as a sum of minterms.

distributive lattice: a lattice that satisfies $a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$ and $a \vee (b \wedge c) = (a \vee b) \wedge (a \vee c)$ for all a, b, c in the lattice.

division ring: a nontrivial ring in which every nonzero element is a unit.

dual (of an expression in a Boolean algebra): the expression obtained by interchanging the operations $+$ and $\cdot$, and interchanging the elements 0 and 1, in the original expression.

duality principle: the principle stating that an identity between Boolean expressions remains valid when the duals of the expressions are taken.

Euclidean domain: an integral domain with a Euclidean norm defined on it.

Euclidean norm (on an integral domain): given an integral domain I, a function $\delta\colon I - \{0\} \to \mathcal{N}$ such that for all $a, b \in I$, $\delta(a) \leq \delta(ab)$; and for all $a, d \in I$ $(d \neq 0)$ there are $q, r \in I$ such that $a = dq + r$, where either $r = 0$ or $\delta(r) < \delta(d)$.

even permutation: a permutation that can be written as a product of an even number of transpositions.

extension field (of field F): a field K such that F is a subfield of K.

field: an algebraic structure $(F, +, \cdot)$ where F is a set closed under two binary operations $+$ and $\cdot$, $(F, +)$ is an abelian group, the nonzero elements form an abelian group under multiplication, and the distributive law $a \cdot (b + c) = a \cdot b + a \cdot c$ holds.

finite field: a field with a finite number of elements.

finitely generated group: a group with a finite set of generators.

fixed field (of a set of automorphisms of a field): given a set Φ of automorphisms of a field F, the set $\{ a \in F \mid a\varphi = a \text{ for all } \varphi \in \Phi \}$.

free monoid (generated by a set): given a set S, the monoid consisting of all words on S under concatenation.

functionally complete: property of a set of operators in a Boolean algebra that every Boolean function can be written using only these operators.

Galois extension (of a field F): a field K that is a normal, separable extension of F.

Galois field: $GF(p^n) =$ the algebraic extension $\mathcal{Z}_p[x]/(f(x))$ of the finite field $\mathcal{Z}_p$ where p is a prime and $f(x)$ is an irreducible polynomial over $\mathcal{Z}_p$ of degree n.

Galois group (of K over F): the group of automorphisms $G(K/F)$ of field K that fix field F elementwise.

group: an algebraic structure $(G, \star)$, where G is a set closed under the binary operation $\star$, the operation $\star$ is associative, G has an identity element, and every element of G has an inverse in G.

homomorphism of groups: a function $\varphi\colon S \to T$, where $(S, \star_1)$ and $(T, \star_2)$ are groups, such that $\varphi(a \star_1 b) = \varphi(a) \star_2 \varphi(b)$ for all $a, b \in S$.

homomorphism of rings: a function $\varphi\colon S \to T$, where $(S, +_1, \cdot_1)$ and $(T, +_2, \cdot_2)$ are rings such that $\varphi(a +_1 b) = \varphi(a) +_2 \varphi(b)$ and $\varphi(a \cdot_1 b) = \varphi(a) \cdot_2 \varphi(b)$ for all $a, b \in S$.

ideal: a subring of a ring that is closed under left and right multiplication by elements of the ring.

identity: an element e in an algebraic structure S such that $e \star a = a \star e = a$ for all $a \in S$.

improper subgroups (of G): the subgroups G and $\{e\}$.

index of H in G: the number of left (or right) cosets of H in G.

integral domain: a commutative ring with unity that has no zero divisors.

inverse of an element a: an element a' such that $a \star a' = a' \star a = e$.

involution: a function that is the identity when it is composed with itself.

irreducible element in a ring: a noninvertible element that cannot be written as the product of noninvertible elements.

irreducible polynomial: a polynomial $p(x)$ of degree $n > 0$ over a field that cannot be written as $p_1(x) \cdot p_2(x)$ where $p_1(x)$ and $p_2(x)$ are polynomials of smaller degrees. Otherwise $p(x)$ is ***reducible***.

isomorphic: property of algebraic structures of the same type, G and H, that there is an isomorphism from G onto H, written $G \cong H$.

isomorphism: a one-to-one and onto function between two algebraic structures that preserves the operations on the structures.

isomorphism of groups: for groups $(G_1, \star_1)$ and $(G_2, \star_2)$, a function $\varphi\colon G_1 \to G_2$ that is one-to-one, onto G_2, and satisfies the property $\varphi(a \star_1 b) = \varphi(a) \star_2 \varphi(b)$.

isomorphism of permutation groups: for permutation groups (G, X) and (H, Y), a pair of functions $(\alpha\colon G \to H, f\colon Y \to Y)$ such that α is a group isomorphism and f is a bijection.

isomorphism of rings: for rings $(R_1, +_1, \cdot_1)$ and $(R_2, +_2, \cdot_2)$, a function $\varphi\colon R_1 \to R_2$ that is one-to-one, onto R_2, and satisfies the properties $\varphi(a +_1 b) = \varphi(a) +_2 \varphi(b)$ and $\varphi(a \cdot_1 b) = \varphi(a) \cdot_2 \varphi(b)$.

kernel (of a group homomorphism): given a group homomorphism φ, the set $\varphi^{-1}(e) = \{ x \mid \varphi(x) = e \}$, where e is the group identity.

kernel (of a ring homomorphism): given a ring homomorphism φ, the set $\varphi^{-1}(0) = \{ x \mid \varphi(x) = 0 \}$.

Klein four-group: the group under composition of the four rigid motions of a rectangle that leave the rectangle in its original location.

lattice: a nonempty partially ordered set in which $\inf\{a, b\}$ and $\sup\{a, b\}$ exist for all a, b. ($a \vee b = \sup\{a, b\}$, $a \wedge b = \inf\{a, b\}$.) Equivalently, a nonempty set closed under two binary operations $\vee$ and $\wedge$ that satisfy the associative laws, the commutative laws, and the absorption laws ($a \vee (a \wedge b) = a$, $a \wedge (a \vee b) = a$).

left divisor of zero: $a \neq 0$ with $b \neq 0$ such that $ab = 0$.

literal: a Boolean variable or its complement.

maximal ideal: an ideal in a ring R that is not properly contained in any ideal of R except R itself.

maxterm of the Boolean variables $x_1, \ldots, x_n$: a sum of the form $y_1 + \cdots + y_n$ where for each i, y_i is equal to x_i or x_i'.

minimal polynomial (of an element with respect to a field): given a field F and $\alpha \in F$, the monic irreducible polynomial $f(x) \in F[x]$ of smallest degree with $f(\alpha) = 0$.

minterm of the Boolean variables $x_1, \ldots, x_n$: a product of the form $y_1 \ldots y_n$ where for each i, y_i is equal to x_i or x_i'.

monadic operation: a function from a set into itself.

monoid: an algebraic structure $(S, \star)$ such that $\star$ is associative and S has an identity.

normal extension of F: a field K such that K/F is algebraic and every irreducible polynomial in $F[x]$ with a root in K has all its roots in K (***splits*** in K).

normal subgroup (of a group): given a group G, a subgroup $H \subseteq G$ such that $aH = Ha$ for all $a \in G$.

octic group: See *dihedral group*.

odd permutation: a permutation that can be written as a product of an odd number of transpositions.

orbit (of an object $a \in S$ under permutation σ): $\{\ldots, a\sigma^{-2}, a\sigma^{-1}, a, a\sigma, a\sigma^2, \ldots\}$.

order (of an algebraic structure): the number of elements in the underlying set.

order (of a group element): for an element $a \in G$, the smallest positive integer n such that $a^n = e$ ($na = 0$ if G is written additively). If there is no such integer, then a has ***infinite*** order.

p-group: for prime p, a group such that every element has a power of p as its order.

permutation: a one-to-one and onto function $\sigma\colon S \to S$, where S is any nonempty set.

permutation group: a collection of permutations on a set of objects that form a group under composition.

polynomial (in the variable x over a ring): an expression of the form $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x^1 + a_0 x^0$ where $a_n, \ldots, a_0$ are elements of the ring. For a polynomial $p(x)$, the largest integer k such that $a_k \neq 0$ is the ***degree*** of $p(x)$. The ***constant polynomial*** $p(x) = a_0$ has degree 0, if $a_0 \neq 0$. If $p(x) = 0$ (the ***zero polynomial***), the degree of $p(x)$ is undefined (or $-\infty$).

polynomial ring (over a ring R): $R[x] = \{p(x) \mid p(x) \text{ is a polynomial in } x \text{ over } R\}$ with the usual definitions of addition and multiplication.

prime ideal (of a ring R): an ideal $I \neq R$ with property that $ab \in I$ implies that $a \in I$ or $b \in I$.

proper subgroup (of a group G): any subgroup of G except G and $\{e\}$.

quotient group (***factor group***): for a normal subgroup H of G, the group $G/H = \{\, aH \mid a \in G \,\}$, where $aH \cdot bH = (ab)H$.

quotient ring: for I an ideal in a ring R, the ring $R/I = \{\, a + I \mid a \in R \,\}$, where $(a+I) + (b+I) = (a+b) + I$ and $(a+I) \cdot (b+I) = (ab) + I$.

reducible (polynomial): a polynomial that is not irreducible.

right divisor of zero: $b \neq 0$ with $a \neq 0$ such that $ab = 0$.

ring: an algebraic structure $(R, +, \cdot)$ where R is a set closed under two binary operations $+$ and $\cdot$, $(R, +)$ is an abelian group, R satisfies the associative law for multiplication, and R satisfies the left and right distributive laws for multiplication over addition.

ring with unity: a ring with an identity for multiplication.

root field: a splitting field.

semigroup: an algebraic structure $(S, \star)$ where S is a nonempty set that is closed under the associative binary operation $\star$.

separable extension (of field F): a field K such that every element of K is the root of a separable polynomial in $F[x]$.

separable polynomial: a polynomial $p(x) \in F[x]$ of degree n that has n distinct roots in its splitting field.

sign (of a permutation): the value $+1$ if the permutation has an even number of transpositions when the permutation is written as a product of transpositions, and -1 otherwise.

simple group: a group whose only normal subgroups are $\{e\}$ and G.

skew field: a division ring.

splitting field (for nonconstant $p(x) \in F[x]$): the field $K = F(\alpha_1, \ldots, \alpha_n)$ where $p(x) = \alpha(x - \alpha_1) \ldots (x - \alpha_n)$, $\alpha \in F$.

subfield (of a field K): a subset $F \subseteq K$ that is a field using the same operations used in K.

subgroup (of a group G): a subset $H \subseteq G$ such that H is a group using the same group operation used in G.

subgroup generated by $\{\, a_i \mid i \in S \,\}$: for a given group G where $a_i \in G$ for all i in S, the smallest subgroup of G containing $\{\, a_i \mid i \in S \,\}$.

subring (of a ring R): a subset $S \subseteq R$ that is a ring using the same operations used in R.

Sylow p-subgroup (of G): a subgroup of G that is a p-group and is not properly contained in any p-group of G.

symmetric group: the group of all permutations on $\{1, 2, \ldots, n\}$ under the operation of composition.

transcendental element (over a field F): given a field F and an extension field K, an element of K that is not a root of any nonzero polynomial in $F[x]$.

transposition: a cycle of length 2.

unary operation: See *monadic operation*.

unit (in a ring): an element with a multiplicative inverse in the ring.

unity (in a ring): a multiplicative identity not equal to 0.

word (on a set): a finite sequence of elements of the set.

zero (of a polynomial f): an element a such that $f(a) = 0$.

5.1 ALGEBRAIC MODELS

5.1.1 DOMAINS AND OPERATIONS

Definitions:

An ***n-ary operation*** on a set S is a function $\star\colon S \times S \times \cdots \times S \to S$, where the domain is the product of n factors.

A ***binary operation*** on a set S is a function $\star\colon S \times S \to S$.

A ***monadic operation*** (or ***unary operation***) on a set S is a function $\star\colon S \to S$.

An ***algebraic structure*** $(S, \star_1, \star_2, \ldots, \star_n)$ consists of a nonempty set S (the ***domain***) with one or more n-ary operations $\star_i$ defined on S.

A binary operation can have some of the following properties:

- ***associative property***: $a \star (b \star c) = (a \star b) \star c$ for all a, b, $c \in S$;
- ***existence of an identity element***: there is an element $e \in S$ such that $e \star a = a \star e = a$ for all $a \in S$ (e is an *identity* for S);
- ***existence of inverses***: for each element $a \in S$ there is an element $a' \in S$ such that $a' \star a = a \star a' = e$ (a' is an *inverse* of a);
- ***commutative property***: $a \star b = b \star a$ for all $a, b \in S$.

Example:

1. The most important types of algebraic structures with one binary operation are listed in the following table. A checkmark means that the property holds.

	closed	*associative*	*commutative*	*existence of identity*	*existence of inverses*
semigroup	√	√			
monoid	√	√			
group	√	√		√	√
abelian group	√	√	√	√	√

5.1.2 SEMIGROUPS AND MONOIDS

Definitions:

A ***semigroup*** $(S, \star)$ consists of a nonempty set S and an associative binary operation $\star$ on S.

A ***monoid*** $(S, \star)$ consists of a nonempty set S and an associative binary operation $\star$ on S such that S has an identity.

A nonempty subset T of a semigroup $(S, \star)$ is a ***subsemigroup*** of S if T is closed under $\star$.

A subset T of a monoid $(S, \star)$ with identity e is a ***submonoid*** of S if T is closed under $\star$ and $e \in T$.

Two semigroups [monoids] $(S_1, \star_1)$ and $(S_2, \star_2)$ are ***isomorphic*** if there is a function $\varphi\colon S_1 \to S_2$ that is one-to-one, onto S_2, and such that $\varphi(a \star_1 b) = \varphi(a) \star_2 \varphi(b)$ for all $a, b \in S_1$.

A ***word*** on a set S (the *alphabet*) is a finite sequence of elements of S.

The ***free monoid*** [***free semigroup***] ***generated by*** S is the monoid [semigroup] $(S^*, \star)$ where S^* is the set of all words on a set S and the operation $\star$ is defined on S^* by *concatenation*: $x_1x_2 \ldots x_m \star y_1y_2 \ldots y_n = x_1x_2 \ldots x_my_1y_2 \ldots y_n$. $(S^*, \star)$ is also called the ***free monoid*** [***free semigroup***] ***on*** S^*.

Facts:

1. Every monoid is a semigroup.

2. Every semigroup $(S, \star)$ is isomorphic to a subsemigroup of some semigroup of transformations on some set. Hence, every semigroup can be regarded as a semigroup of transformations. An analogous result is true for monoids.

Examples:

1. *Free semigroups and monoids*: The free monoid generated by S is a monoid with the empty word $e = \lambda$ (the sequence consisting of zero elements) as the identity.

2. The possible input tapes to a computer form a free monoid on the set of symbols (such as the ASCII symbols) in the computer alphabet.

3. *Semigroup and monoid of transformations on a set S*: Let S be a nonempty set and let $\mathcal{F}$ be the set of all functions $f\colon S \to S$. With the operation $\star$ defined by composition, $(f \star g)(x) = f(g(x))$, $(\mathcal{F}, \star)$ is the *semigroup* [*monoid*] *of transformations on* S. The identity of $\mathcal{F}$ is the identity transformation $e\colon S \to S$ where $e(x) = x$ for all $x \in S$.

4. The set of closed walks based at a fixed vertex v in a graph forms a monoid under the operation of concatenation. The null walk is the identity. (§8.4.1.)

5. For a fixed positive integer n, the set of all $n \times n$ matrices with elements in any ring with unity (§5.4.1) where $\star$ is matrix multiplication (using the operations in the ring) is a semigroup and a monoid. The identity is the identity matrix.

6. The sets

$\mathcal{N} = \{0, 1, 2, 3, \ldots\}$ (natural numbers),
$\mathcal{Z} = \{\ldots, -2, -1, 0, 1, 2, \ldots\}$ (integers),
$\mathcal{Q}$ (the set of rational numbers),
$\mathcal{R}$ (the set of real numbers),
$\mathcal{C}$ (the set of complex numbers),

where $\star$ is either addition or multiplication, are all semigroups and monoids. Using either addition or multiplication, each semigroup is a subsemigroup of each of those following it in this list. Likewise, using either addition or multiplication, each monoid is a submonoid of each of those following it in this list. For example, $(\mathcal{Q}, +)$ is a subsemigroup and submonoid of $(\mathcal{R}, +)$ and $(\mathcal{C}, +)$. Under addition, $e = 0$; under multiplication, $e = 1$.

5.2 GROUPS

5.2.1 BASIC CONCEPTS

Definitions:

A ***group*** $(G, \star)$ consists of a set G with a binary operator $\star$ defined on G such that $\star$ has the following properties:

- ***associative property***: $a \star (b \star c) = (a \star b) \star c$ for all a, b, $c \in G$;
- ***identity property***: G has an element e (*identity* of G) that satisfies $e \star a = a \star e = a$ for all $a \in G$;
- ***inverse property***: for each element $a \in G$ there is an element $a^{-1} \in G$ (*inverse* of a) such that $a^{-1} \star a = a \star a^{-1} = e$.

If $a \star b = b \star a$ for all $a, b \in G$, the group G is ***commutative*** or ***abelian***. (Niels H. Abel, 1802–1829)

The ***order*** of a finite group G, denoted $|G|$, is the number of elements in the group.

The (***external***) ***direct product*** of groups $(G_1, \star_1)$ and $(G_2, \star_2)$ is the group $G_1 \times G_2 = \{(a_1, a_2) \mid a_1 \in G_1,\ a_2 \in G_2\}$ where multiplication $\star$ is defined by the rule $(a_1, a_2) \star (b_1, b_2) = (a_1 \star_1 b_1, a_2 \star_2 b_2)$. The direct product can be extended to n groups: $G_1 \times G_2 \times \cdots \times G_n$. The direct product is also called the ***direct sum*** and written $G_1 \oplus G_2 \oplus \cdots \oplus G_n$, especially if the groups are abelian. If $G_i = G$ for all i, the direct product can be written G^n.

The group G is ***finitely generated*** if there are $a_1, a_2, \ldots, a_n \in G$ such that every element of G can be written as $a_{k_1}^{\epsilon_1} a_{k_2}^{\epsilon_2} \ldots a_{k_j}^{\epsilon_j}$ where $k_i \in \{1, \ldots, n\}$ and $\epsilon_i \in \{1, -1\}$, for some $j \geq 0$; where the empty product is defined to be e.

Note: Frequently the operation $\star$ is multiplication or addition. If the operation is addition, the group $(G, +)$ is an *additive group*. If the operation is multiplication, the group $(G, \cdot)$ is a *multiplicative group*.

	operation $*$	*identity* e	*inverse* a^{-1}
additive group	$a+b$	0	$-a$
multiplicative group	$a \cdot b$ *or* ab	1 *or* e	a^{-1}

Facts:

1. Every group has exactly one identity element.

2. In every group every element has exactly one inverse.

3. *Cancellation laws*: In all groups,

- if $ab = ac$ then $b = c$ (*left cancellation law*);
- if $ba = ca$, then $b = c$ (*right cancellation law*).

4. $(a^{-1})^{-1} = a$.

5. $(ab)^{-1} = b^{-1}a^{-1}$. More generally, $(a_1a_2 \ldots a_k)^{-1} = a_k^{-1}a_{k-1}^{-1} \ldots a_1^{-1}$.

6. If a and b are elements of a group G, the equations $ax = b$ and $xa = b$ have unique solutions in G. The solutions are $x = a^{-1}b$ and $x = ba^{-1}$, respectively.

7. The direct product $G_1 \times \cdots \times G_n$ is abelian when each group G_i is abelian.

8. $|G_1 \times \cdots \times G_n| = |G_1| \cdot \cdots \cdot |G_n|$.

9. The identity for $G_1 \times \cdots \times G_n$ is $(e_1, \ldots, e_n)$ where e_i is the identity of G_i. The inverse of $(a_1, \ldots, a_n)$ is $(a_1, \ldots, a_n)^{-1} = (a_1^{-1}, \ldots, a_n^{-1})$.

10. The structure of a group can be determined by a single rule (see Example 2) or by a group table listing all products (see Examples 2 and 3).

Examples:

1. Table 1 displays information on several common groups. All groups listed have infinite order, except for the following: the group of complex nth roots of unity has order n, the group of all bijections $f\colon S \to S$ where $|S| = n$ has order $n!$, $\mathcal{Z}_n$ has order n, $\mathcal{Z}_n^*$ has order $\phi(n)$ (Euler phi-function), S_n has order $n!$, A_n has order $n!/2$, D_n has order $2n$, and the quaternion group has order 8.

All groups listed in the table are abelian except for: the group of bijections, $GL(n, \mathcal{R})$, S_n, A_n, D_n, and $\mathbf{Q}$.

Table 1: Examples of groups.

set	*operation*	*identity*	*inverses*
$\mathcal{Z}$, $\mathcal{Q}$, $\mathcal{R}$, $\mathcal{C}$	addition	0	$-a$
$\mathcal{Z}^n$, n a positive integer (also $\mathcal{Q}^n$, $\mathcal{R}^n$, $\mathcal{C}^n$)	coordinatewise addition	$(0, \ldots, 0)$	$-(a_1, \ldots, a_n) = (-a_1, \ldots, -a_n)$
the set of all complex numbers of modulus $1 = \{e^{i\theta} = \cos\theta + i \sin\theta \mid 0 \le \theta < 2\pi\}$	multiplication	$e^{i0} = 1$	$(e^{i\theta})^{-1} = e^{-i\theta}$
the *complex nth roots of unity* (solutions to $z^n = 1$) $\{e^{2\pi ik/n} \mid k = 0, 1, \ldots, n-1\}$	multiplication	1	$(e^{2\pi ik/n})^{-1} = e^{2\pi i(n-k)/n}$
$\mathcal{R}-\{0\}$, $\mathcal{Q}-\{0\}$, $\mathcal{C}-\{0\}$	multiplication	1	$1/a$
$\mathcal{R}^*$ (positive real numbers)	multiplication	1	$1/a$

set	*operation*	*identity*	*inverses*
all rotations of the plane around the origin; $r_\alpha =$ counterclockwise rotation through an angle of $\alpha°$: $r_\alpha(x,y) = (x\cos\alpha - y\sin\alpha,$ $x\sin\alpha + y\sin\alpha)$	composition: $r_{\alpha_2} \circ r_{\alpha_1} = r_{\alpha_1+\alpha_2}$	r_0 (the 0° rotation)	$r_\alpha^{-1} = r_{-\alpha}$
all 1–1, onto functions (bijections) $f\colon S \to S$ where S is any nonempty set	composition of functions	$i\colon S \to S$ where $i(x) = x$ for all $x \in S$	$f^{-1}(y) = x$ if and only if $f(x) = y$
$\mathcal{M}_{m\times n} =$ all $m \times n$ matrices with entries in $\mathcal{R}$	matrix addition	$0_{m\times n}$ (zero matrix)	$-A$
$GL(n,\mathcal{R}) =$ all $n \times n$ invertible, or nonsingular, matrices with entries in $\mathcal{R}$; (the *general linear group*)	matrix multiplication	I_n (identity matrix)	A^{-1}
$\mathcal{Z}_n = \{0,1,\ldots,n-1\}$	$(a+b)\,\mathbf{mod}\ n$	0	$n-a$ $(a \neq 0)$ $-0=0$
$\mathcal{Z}_n^* = \{k \mid k \in \mathcal{Z}_n,\ k$ relatively prime to $n\}$, $n > 1$	$ab\,\mathbf{mod}\ n$	1	see Example 2
$S_n =$ all permutations of $\{1,2,\ldots,n\}$; (*symmetric group*) (See §5.3.)	composition of permutations	identity permutation	inverse permutation
$A_n =$ all even permutations of $\{1,2,\ldots,n\}$; (*alternating group*) (See §5.3.)	composition of permutations	identity permutation	inverse permutation
$D_n =$ symmetries (rotations and reflections) of a regular n-gon; (*dihedral group*)	composition of functions	rotation through 0°	$r_\alpha^{-1} = r_{-\alpha}$; reflections are their own inverses
$\mathbf{Q} =$ *quaternion group* (see Example 3)			

2. *The groups $\mathcal{Z}_n$ and $\mathcal{Z}_n^*$* (see Table 1): In the groups $\mathcal{Z}_n$ and $\mathcal{Z}_n^*$ an element a can be viewed as the equivalence class $\{b \in \mathcal{Z} \mid b\ \mathbf{mod}\ n = a\ \mathbf{mod}\ n\}$, which can be written $\overline{a}$ or $[a]$. To find the inverse a^{-1} of $a \in \mathcal{Z}_n^*$, use the extended Euclidean algorithm to find integers a^{-1} and k such that $aa^{-1} + nk = \gcd(a,n) = 1$. The following are the group tables for $\mathcal{Z}_2 = \{0,1\}$ and $\mathcal{Z}_3 = \{0,1,2\}$:

+	0	1
0	0	1
1	1	0

+	0	1	2
0	0	1	2
1	1	2	0
2	2	0	1

3. *Quaternion group*: $\mathbf{Q} = \{1,-1,i,-i,j,-j,k,-k\}$ where multiplication is defined by the following relations:

$$i^2 = j^2 = k^2 = -1, \qquad ij = -ji = k, \qquad jk = -kj = i, \qquad ki = -ik = j$$

where 1 is the identity. These relations yield the multiplication table shown next. Here, $1^{-1} = 1$, $(-1)^{-1} = -1$, x and $-x$ are inverses for $x = i, j, k$. The group is nonabelian.

$\cdot$	1	-1	i	$-i$	j	$-j$	k	$-k$
1	1	-1	i	$-i$	j	$-j$	k	$-k$
-1	-1	1	$-i$	i	$-j$	j	$-k$	k
i	i	$-i$	-1	1	k	$-k$	$-j$	j
$-i$	$-i$	i	1	-1	$-k$	k	j	$-j$
j	j	$-j$	$-k$	k	-1	1	i	$-i$
$-j$	$-j$	j	k	$-k$	1	-1	$-i$	i
k	k	$-k$	j	$-j$	$-i$	i	-1	1
$-k$	$-k$	k	$-j$	j	i	$-i$	1	-1

The quaternion group $\mathbf{Q}$ can also be defined as the following group of 8 matrices, where i is the complex number such that $i^2 = -1$ and the group operation is matrix multiplication.

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}, \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix},$$

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}$$

4. The set $\{a, b, c, d\}$ with either of the following multiplication tables is not a group. In the first case there is an identity, a, and each element has an inverse, but the associative law fails: $(bc)d \neq b(cd)$. In the second case there is no identity (hence inverses are not defined) and the associative law fails.

$\cdot$	a	b	c	d
a	a	b	c	d
b	b	d	a	c
c	c	a	b	d
d	d	c	b	a

$\cdot$	a	b	c	d
a	a	c	b	d
b	d	b	a	c
c	b	d	c	a
d	c	a	d	b

5.2.2 GROUP ISOMORPHISM AND HOMOMORPHISM

Definitions:

For groups G and H, a function $\varphi\colon G \to H$ such that $\varphi(ab) = \varphi(a)\varphi(b)$ for all $a, b \in G$ is a ***homomorphism***. The notation $a\varphi$ is sometimes used instead of $\varphi(a)$.

For groups G and H, a function $\varphi\colon G \to H$ is an ***isomorphism*** from G to H if φ is a homomorphism that is 1–1 and onto H. In this case G is ***isomorphic*** to H, written $G \cong H$.

An isomorphism $\varphi\colon G \to G$ is an ***automorphism***.

The ***kernel*** of φ is the set $\{g \in G \mid \varphi(g) = e\}$, where e is the identity of the group G.

Facts:

1. If φ is an isomorphism, φ^{-1} is an isomorphism.

2. Isomorphism is an equivalence relation: $G \cong G$ (reflexive); if $G \cong H$, then $H \cong G$ (symmetric); if $G \cong H$ and $H \cong K$, then $G \cong K$ (transitive).

3. If $\varphi\colon G \to H$ is a homomorphism, then $\varphi(G)$ is a group (a subgroup of H).

4. If $\varphi\colon G \to H$ is a homomorphism, then the kernel of φ is a group (a subgroup of G).

5. If p is prime there is only one group of order p (up to isomorphism), the group $(\mathcal{Z}_p,+)$.

6. *Cayley's theorem*: If G is a finite group of order n, then G is isomorphic to a subgroup of the group S_n of permutations on n objects. (Arthur Cayley, 1821–1895) The isomorphism is obtained by associating with each $a \in G$ the map $\pi_a\colon G \to G$ given by the rule $\pi_a(g) = ga$ for all $g \in G$.

7. $\mathcal{Z}_m \times \mathcal{Z}_n$ is isomorphic to $\mathcal{Z}_{mn}$ if and only if m and n are relatively prime.

8. If $n = n_1 n_2 \ldots n_k$ where the n_i are powers of distinct primes, then $\mathcal{Z}_n$ is isomorphic to $\mathcal{Z}_{n_1} \times \mathcal{Z}_{n_2} \times \cdots \times \mathcal{Z}_{n_k}$.

9. *Fundamental theorem of finite abelian groups*: Every finite abelian group G (order ≥ 2) is isomorphic to a direct product of cyclic groups where each cyclic group has order a power of a prime. That is, G is isomorphic to $\mathcal{Z}_{n_1} \times \mathcal{Z}_{n_2} \times \cdots \times \mathcal{Z}_{n_k}$ where each cyclic order n_i is a power of some prime. In addition, the set $\{n_1, \ldots, n_k\}$ is unique.

10. Every finite abelian group is isomorphic to a subgroup of $\mathcal{Z}_n^*$ for some n.

11. *Fundamental theorem of finitely generated abelian groups*: If G is a finitely generated abelian group, then there are unique integers $n \geq 0$, $n_1, n_2, \ldots, n_k \geq 2$ where $n_{i+1} \,|\, n_i$ for $i = 1, 2, \ldots, k-1$ such that G is isomorphic to $\mathcal{Z}^n \times \mathcal{Z}_{n_1} \times \mathcal{Z}_{n_2} \times \cdots \times \mathcal{Z}_{n_k}$.

Examples:

1. The following table lists the number of nonisomorphic groups and abelian groups of all orders from 1 to 60.

order	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
groups	1	1	1	2	1	2	1	5	2	2	1	5	1	2	1	14	1	5	1	5
abelian	1	1	1	2	1	1	1	3	2	1	1	2	1	1	1	5	1	2	1	2
order	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40
groups	2	2	1	15	2	2	5	4	1	4	1	51	1	2	1	14	1	2	2	14
abelian	1	1	1	3	2	1	3	2	1	1	1	7	1	1	1	4	1	1	1	3
order	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60
groups	1	6	1	4	2	2	1	52	2	5	1	5	1	15	2	13	2	2	1	13
abelian	1	1	1	2	2	1	1	5	2	2	1	2	1	3	1	3	1	1	1	2

2. All groups of order 12 or less are listed by order in the following table.

order	*groups*
1	$\{e\}$
2	$\mathcal{Z}_2$
3	$\mathcal{Z}_3$
4	$\mathcal{Z}_4$, if there is an element of order 4 (group is cyclic) $\mathcal{Z}_2 \times \mathcal{Z}_2 \cong$ Klein four-group, if no element has order 4 (§5.3.2)

order	*groups*
5	$\mathcal{Z}_5$
6	$\mathcal{Z}_6$, if there is an element of order 6 (group is cyclic) $S_3 \cong D_3$, if there is no element of order 6 (§5.3.1, §5.3.2)
7	$\mathcal{Z}_7$
8	$\mathcal{Z}_8$, if there is an element of order 8 (group is cyclic) $\mathcal{Z}_2 \times \mathcal{Z}_4$, if there is an element a of order 4, but none of order 8, and if there is an element $b \notin (a)$ such that $ab = ba$ and $b^2 = e$ $\mathcal{Z}_2 \times \mathcal{Z}_2 \times \mathcal{Z}_2$, if every element has order 1 or 2 D_4, if there is an element a of order 4, but none of order 8, and if there is an element $b \notin (a)$ such that $ba = a^3b$ and $b^2 = e$ Quaternion group, if there is an element a of order 4, none of order 8, and an element $b \notin (a)$ such that $ba = a^3b$ and $b^2 = a^2$ (§5.2.1)
9	$\mathcal{Z}_9$, if there is an element of order 9 (group is cyclic) $\mathcal{Z}_3 \times \mathcal{Z}_3$, if there is no element of order 9
10	$\mathcal{Z}_{10}$, if there is an element of order 10 (group is cyclic) D_5, if there is no element of order 10
11	$\mathcal{Z}_{11}$
12	$\mathcal{Z}_{12} \cong \mathcal{Z}_3 \times \mathcal{Z}_4$, if there is an element of order 12 (group is cyclic) $\mathcal{Z}_2 \times \mathcal{Z}_6 \cong \mathcal{Z}_2 \times \mathcal{Z}_2 \times \mathcal{Z}_3$, if group is abelian but noncyclic D_6, if group is nonabelian and has an element of order 6 but none of order 4 A_4, if group is nonabelian and has no element of order 6 The group generated by a and b, where a has order 4, b has order 3, and $ab = b^2a$

5.2.3 SUBGROUPS

Definitions:

A ***subgroup*** of a group $(G, \star)$ is a subset $H \subseteq G$ such that $(H, \star)$ is a group (with the same group operation as in G). Write $H \leq G$ if H is a subgroup of G.

If $a \in G$, the set $(a) = \{\ldots, a^{-2} = (a^{-1})^2, a^{-1}, a^0 = e, a, a^2, \ldots\} = \{a^n \mid n \in \mathcal{Z}\}$ is the ***cyclic subgroup*** generated by a. The element a is a ***generator*** of G.

G and $\{e\}$ are ***improper subgroups*** of G. All other subgroups of G are ***proper subgroups*** of G.

Facts:

1. If G is a group, then $\{e\}$ and G are subgroups of G.

2. If G is a group and $a \in G$, the set (a) is a subgroup of G.

3. Every subgroup of an abelian group is abelian.

4. If H is a subgroup of a group G, then the identity element of H is the identity element of G; the inverse (in the subgroup H) of an element a in H is the inverse (in the group G) of a.

5. *Lagrange's theorem*: Let G be a finite group. If H is any subgroup of G, then the order of H is a divisor of the order of G. (Joseph-Louis Lagrange, 1736–1813)

6. If d is a divisor of the order of a group G, there may be no subgroup of order d. (The group A_4, of order 12, has no subgroup of order 6. See §5.3.2.)

7. If G is a finite abelian group, then the converse of Lagrange's theorem is true for G.

8. If G is finite (not necessarily abelian) and p is a prime that divides the order of G, then G has a subgroup of order p.

9. If G has order $p^m n$ where p is prime and p does not divide n, then G has a subgroup of order p^m, called a *Sylow subgroup* or *Sylow p-subgroup*. See §5.2.6.

10. A subset H of a group G is a subgroup of G if and only if the following are all true: $H \neq \emptyset$; $a, b \in H$ implies $ab \in H$; and $a \in H$ implies $a^{-1} \in H$.

11. A subset H of a group G is a subgroup of G if and only if $H \neq \emptyset$ and $a, b \in H$ implies that $ab^{-1} \in H$.

12. If H is a nonempty finite subset of a group G with the property that a, $b \in H$ implies that $ab \in H$, then H is a subgroup of G.

13. The intersection of any collection of subgroups of a group G is a subgroup of G.

14. The union of subgroups is not necessarily a subgroup. See Example 12.

Examples:

1. *Additive subgroups*: Each of the following can be viewed as a subgroup of all the groups listed after it: $(\mathcal{Z}, +)$, $(\mathcal{Q}, +)$, $(\mathcal{R}, +)$, $(\mathcal{C}, +)$.

2. For n any positive integer, the set $n\mathcal{Z} = \{nz \mid z \in \mathcal{Z}\}$ is a subgroup of $\mathcal{Z}$.

3. $\mathcal{Z}_2$ is not a subgroup of $\mathcal{Z}_4$ (the group operations are not the same).

4. The set of odd integers under addition is not a subgroup of $(\mathcal{Z}, +)$ (the set of odd integers is not closed under addition).

5. $(\mathcal{N}, +)$ is not a subgroup of $(\mathcal{Z}, +)$ ($\mathcal{N}$ does not contain its inverses).

6. The group $\mathcal{Z}_6$ has the following four subgroups: $\{0\}$, $\{0, 3\}$, $\{0, 2, 4\}$, $\mathcal{Z}_6$.

7. *Multiplicative subgroups*: Each of the following can be viewed as a subgroup of all the groups listed after it: $(\mathcal{Q} - \{0\}, \cdot)$, $(\mathcal{R} - \{0\}, \cdot)$, $(\mathcal{C} - \{0\}, \cdot)$.

8. The set of n complex nth roots of unity can be viewed as a subgroup of the set of all complex numbers of modulus 1 under multiplication, which is a subgroup of $(\mathcal{C} - \{0\}, \cdot)$.

9. If $nd = 360$ (n and d positive integers) and r_k is the counterclockwise rotation of the plane about the origin through an angle of k°, then $\{r_k \mid k = 0, d, 2d, 3d, \ldots, (n-1)d\}$ is a subgroup of the group of all rotations of the plane around the origin.

10. The set of all $n \times n$ nonsingular diagonal matrices is a subgroup of the set of all $n \times n$ nonsingular matrices under multiplication.

11. If $n = mk$, then $\{0, m, 2m, \ldots, (k-1)m\}$ is a subgroup of $(\mathcal{Z}_n, +)$ isomorphic to $\mathcal{Z}_k$.

12. The union of subgroups need not be a subgroup: $\{2n \mid n \in \mathcal{Z}\}$ and $\{3n \mid n \in \mathcal{Z}\}$ are subgroups of $\mathcal{Z}$, but their union is not a subgroup of $\mathcal{Z}$ since $2 + 3 = 5 \notin \{2n \mid n \in \mathcal{Z}\} \cup \{3n \mid n \in \mathcal{Z}\}$.

5.2.4 COSETS AND QUOTIENT GROUPS

Definitions:

If H is a subgroup of a group G and $a \in G$, then the set $aH = \{ah \mid h \in H\}$ is a ***left coset*** of H in G. The set $Ha = \{ha \mid h \in H\}$ is a ***right coset*** of H in G. (If G is written additively, the cosets are written $a + H$ and $H + a$.)

The ***index*** of a subgroup H in a group G, written $(G\colon H)$ or $[G\colon H]$, is the number of left (or right) cosets of H in G.

A ***normal*** subgroup of a group G is a subgroup H of G such that $aH = Ha$ for all $a \in G$. The notation $H \lhd G$ means that H is a normal subgroup of G.

If H is a normal subgroup of G, the ***quotient group*** (or ***factor group of G modulo H***) is the group $G/H = \{aH \mid a \in G\}$, where $aH \cdot bH = (ab)H$.

If G is a group and $a \in G$, an element $b \in G$ is a ***conjugate*** of a if $b = gag^{-1}$ for some $g \in G$.

If G is a group and $a \in G$, the set $\{x \mid x \in G,\ ax = xa\}$ is the ***centralizer*** (or ***normalizer***) of a.

If G is a group, the set $\{x \mid x \in G,\ gx = xg \text{ for all } g \in G\}$ is the ***center*** of G.

If H is a subgroup of group G, the set $\{x \mid x \in G,\ xHx^{-1} = H\}$ is the ***normalizer*** of H.

Facts:

1. If H is a subgroup of a group G, then the following are equivalent:

- H is a normal subgroup of G;
- $aHa^{-1} = a^{-1}Ha = H$ for all $a \in G$;
- $a^{-1}ha \in H$ for all $a \in G$, $h \in H$;
- for all $a \in G$ and $h_1 \in H$, there is $h_2 \in H$ such that $ah_1 = h_2a$.

2. If group G is abelian, then every subgroup H of G is normal. If G is not abelian, it may happen that H is not normal.

3. If group G is finite, then $(G\colon H) = |G|/|H|$.

4. $\{e\}$ and G are normal subgroups of group G.

5. In the group G/H, the identity is $eH = H$ and the inverse of aH is $a^{-1}H$.

6. *Fundamental homomorphism theorem*: If $\varphi\colon G \to H$ is a homomorphism and has kernel K, then K is a normal subgroup of G and G/K is isomorphic to $\varphi(G)$.

7. If H is a normal subgroup of a group G and $\varphi\colon G \to G/H$ is defined by $\varphi(g) = gH$, then φ is a homomorphism onto G/H with kernel H.

8. If H is a normal subgroup of a finite group G, then G/H has $|G|/|H|$ cosets.

9. If H and K are normal subgroups of a group G, then $H \cap K$ is a normal subgroup of G.

10. For all $a \in G$, the centralizer of a is a subgroup of G.

11. The center of a group is a subgroup of the group.

12. The normalizer of a subgroup of group G is a subgroup of G.

13. The index of the centralizer of $a \in G$ is equal to the number of distinct conjugates of a in G.

14. If a group G contains normal subgroups H and K such that $H \cap K = \{e\}$ and $\{hk \mid h \in H, k \in K\} = G$, then G is isomorphic to $H \times K$.

15. If G is a group such that $|G| = ab$ where a and b are relatively prime, and if G contains normal subgroups H of order a and K of order b, then G is isomorphic to $H \times K$.

Examples:

1. $\mathcal{Z}/n\mathcal{Z}$ is isomorphic to $\mathcal{Z}_n$, since $\varphi\colon \mathcal{Z} \to \mathcal{Z}_n$ defined by $\varphi(g) = g \textbf{ mod } n$ has kernel $n\mathcal{Z}$.

2. The left cosets of the subgroup $H = \{0,4\}$ in $\mathcal{Z}_8$ are $H+0 = \{0,4\}$, $H+1 = \{1,5\}$, $H+2 = \{2,6\}$, $H+3 = \{3,7\}$. The index of H in $\mathcal{Z}_8$ is $(\mathcal{Z}_8, H) = 4$.

3. $\{(1),(12)\}$ is not a normal subgroup of the symmetric group S_3 (§5.3.1).

5.2.5 CYCLIC GROUPS AND ORDER

Definitions:

A group $(G,\cdot)$ is ***cyclic*** if there is $a \in G$ such that $G = \{a^n \mid n \in \mathcal{Z}\}$, where $a^0 = e$ and $a^{-n} = (a^{-1})^n$ for all positive integers n. If G is written additively, $G = \{na \mid n \in \mathcal{Z}\}$, where $0a = 0$ and if $n > 0$, $na = a + a + a + \cdots + a$ (n terms) and $-na = (-a) + (-a) + \cdots + (-a)$ (n terms).

The element a is called a ***generator*** of G and the group $(G,\cdot)$ is written $((a),\cdot)$, (a), or $\langle a\rangle$.

The ***order of an element*** $a \in G$, written $|(a)|$ or $\text{ord}(a)$, is the smallest positive integer n such that $a^n = e$ ($na = 0$ if G is written additively). If there is no such integer, then a has ***infinite*** order.

A subgroup H of a group $(G,\cdot)$ is a ***cyclic subgroup*** if there exists $a \in H$ such that $H = \{a^n \mid n \in \mathcal{Z}\}$.

Facts:

1. The order of an element a is equal to the number of elements in (a).

2. Every group of prime order is cyclic.

3. Every cyclic group is abelian. However, not every abelian group is cyclic: for example, $(\mathcal{R},+)$ and the Klein four-group.

4. If G is an infinite cyclic group, then $G \cong (\mathcal{Z},+)$.

5. If G is a finite cyclic group of order n, then $G \cong (\mathcal{Z}_n,+)$.

6. If G is a group of order n, then the order of every element of G is a divisor of n.

7. *Cauchy's theorem*: If G is a group of order n and p is a prime that divides n, then G contains an element of order p. (Augustin-Louis Cauchy, 1789–1857)

8. If G is a cyclic group of order n generated by a, then $G = \{a, a^2, a^3, \ldots, a^n\}$ and $a^n = e$. If k and n are relatively prime, then a^k is also a generator of G, and conversely.

9. If G is a group and $a \in G$, then (a) is a cyclic subgroup of G.

10. Every subgroup of a cyclic group is cyclic.

11. If G is a group of order n and there is an element $a \in G$ of order n, then G is cyclic and $G = (a)$.

Examples:

1. $(\mathcal{Z}, +)$ is cyclic and is generated by each of 1 and -1.

2. $(\mathcal{Z}_n, +)$ is cyclic and is generated by each element of $\mathcal{Z}_n$ that is relatively prime to n. If $a \in \mathcal{Z}_n$, then a has order $n/\gcd(a, n)$.

3. $(\mathcal{Z}_p, +)$, p prime, is a cyclic group generated by each of the elements $1, 2, \ldots, p-1$. If $a \neq 0$, a has order p.

4. $(\mathcal{Z}_n^*, \cdot)$ is cyclic if and only if $n = 2$, 4, p^k, or $2p^k$, where $k \geq 1$ and p is an odd prime.

5.2.6 SYLOW THEORY

The Sylow theorems are used to help classify the nonisomorphic groups of a given order by guaranteeing the existence of subgroups of certain orders. (Peter Ludvig Mejdell Sylow, 1832–1918)

Definitions:

For prime p, a group G is a ***p*-group** if every element of G has order p^n for some $n \geq 0$.

For prime p, a ***Sylow p-subgroup*** (***Sylow subgroup***) of G is a subgroup of G that is a p-group and is not properly contained in any p-group in G.

Facts:

1. *Sylow's theorem*: If G is a group of order $p^m \cdot q$ where p is a prime, $m \geq 1$, and p does not divide q, then

- G contains subgroups of orders $p, p^2, \ldots, p^m$ (hence, if prime p divides the order of a finite group G, then G contains an element of order p);
- if H and K are Sylow p-subgroups of G, there is $g \in G$ such that $K = gHg^{-1}$ (K is *conjugate* to H);
- the number of Sylow p-subgroups of G is $kp + 1$ for some integer k such that $(kp+1) \mid q$.

2. If G is a group of order pq where p and q are primes and $p < q$, then G contains a normal subgroup of order q.

3. If G is a group of order pq where p and q are primes, $p < q$, and p does not divide $q - 1$, then G is cyclic.

Examples:

1. Every group of order 15 is cyclic (by Fact 3).

2. Every group of order 21 contains a normal subgroup of order 7 (by Fact 2).

5.2.7 SIMPLE GROUPS

Simple groups arise as a fundamental part of the study of finite groups and the structure of their subgroups. An extensive, lengthy search by many mathematicians for all finite simple groups ended in 1980 when, as the result of hundreds of articles written by over one hundred mathematicians, the classification of all finite simple groups was completed. See [As00] and [Go82] for details.

Definitions:

A group $G \neq \{e\}$ is ***simple*** if its only normal subgroups are $\{e\}$ and G.

A ***composition series*** for a group G is a finite sequence of subgroups $H_1 = G$, $H_2, \ldots,$ H_{n-1}, $H_n = \{e\}$ such that H_{i+1} is a normal subgroup of H_i and H_i/H_{i+1} is simple, for $i = 1, \ldots, n-1$.

A finite group G is ***solvable*** if it has a sequence of subgroups $H_1 = G$, $H_2, \ldots,$ H_{n-1}, $H_n = \{e\}$ such that H_{i+1} is a normal subgroup of H_i and H_i/H_{i+1} is abelian, for $i = 1, \ldots, n-1$.

A ***sporadic*** group is one of 26 nonabelian finite simple groups that is not an alternating group or a group of Lie type [Go82].

Facts:

1. Every finite group has a composition series. Thus, simple groups (the quotient groups in the series) can be regarded as the building blocks of finite groups.

2. Some infinite groups, such as $(\mathcal{Z}, +)$, do not have composition series.

3. Every abelian group is solvable.

4. An abelian group G is simple if and only if $G \cong \mathcal{Z}_p$ where p is prime.

5. If G is a nonabelian solvable group, then G is not simple.

6. Every group of prime order is simple.

7. Every group of order p^n (p prime) is solvable.

8. Every group of order $p^n q^m$ (p, q primes) is solvable.

9. If G is a solvable, simple finite group, then G is either $\{e\}$ or $\mathcal{Z}_p$ (p prime).

10. If G is a simple group of odd order, then $G \cong \mathcal{Z}_p$ for some prime p.

11. There is no infinite simple, solvable group.

12. *Burnside's conjecture/Feit-Thompson theorem*: In 1911 William Burnside conjectured that all groups of odd order are solvable. This conjecture was proved in 1963 by Walter Feit and John Thompson. (See Fact 13.)

13. Every nonabelian simple group has even order. (This follows from the Feit-Thompson theorem.)

14. The proof of the Burnside conjecture provided the impetus for a massive program to classify all finite simple groups. This program, organized by Daniel Gorenstein, led to hundreds of journal articles and concluded in 1980 when the classification problem was finally solved (Fact 15). [GoLySo02]

15. *Classification theorem for finite simple groups*: Every finite simple group is of one of the following types:

- *abelian*: $\mathcal{Z}_p$ where p is prime (§5.2.1);
- *nonabelian*:
  - ◇ alternating groups A_n ($n \neq 4$) (§5.3.2);
  - ◇ groups of *Lie* type, which fall into 6 classes of classical groups and 10 classes of exceptional simple groups [Ca89];
  - ◇ *sporadic* groups. There are 26 sporadic groups, listed here from smallest to largest order. The letters in the names of the groups reflect the names of some of the people who conjectured the existence of the groups or proved the groups simple. M_{11} (order 7,920), M_{12}, M_{22}, M_{23}, M_{24}, J_1, J_2, J_3, J_4, HS, Mc, Suz, Ru, He, Ly, ON, .1, .2, .3, $M(22)$, $M(23)$, $M(24)'$, F_5, F_3, F_2, F_1 (*the monster* or *Fischer-Griess* group of order $\approx 10^{54}$).

5.2.8 GROUP PRESENTATIONS

Definitions:

The ***balanced alphabet*** on the set $X = \{x_1, \ldots, x_n\}$ is the set $\{x_1, x_1^{-1}, \ldots, x_n, x_n^{-1}\}$, whose elements are often called ***symbols***.

Symbols x_j and x_j^{-1} of a balanced alphabet are ***inverses*** of each other. A double inverse $(x_j^{-1})^{-1}$ is understood as the identity operator.

A ***word*** in X is a string $s_1 s_2 \ldots s_n$ of symbols from the balanced alphabet on X.

The ***inverse of a word*** $s = s_1 s_2 \ldots s_n$ is the word $s^{-1} = s_n^{-1} \ldots s_2^{-1} s_1^{-1}$.

The ***free semigroup*** $W(X)$ has the set of words in X as its domain and string concatenation as its product operation.

A ***trivial relator*** in the set $X = \{x_1, \ldots, x_n\}$ is a word of the form $x_j x_j^{-1}$ or $x_j^{-1} x_j$.

A word u is ***freely equivalent*** to a word v, denoted $u \sim v$, if v can be obtained from u by iteratively inserting and deleting trivial relators, in the usual sense of those string operations. This is an equivalence relation, whose classes are called ***free equivalence classes***.

A ***reduced word*** is a word containing no instances of a trivial relator as a substring.

The ***free group*** $F[X]$ has the set of free equivalence classes of words in X as its domain and class concatenation as its product operation.

A ***group presentation*** is a pair $(X \colon R)$, where X is an alphabet and R is a set of words in X called ***relators***. A group presentation is ***finite*** if X and R are both finite.

A word u is ***R-equivalent*** to a word v under the group presentation $(X \colon R)$, denoted $u \sim_R v$, if v can be obtained from u by iteratively inserting and deleting relators from R or trivial relators. This is an equivalence relation, whose classes are called ***R-equivalence classes***.

The group $\mathcal{G}(X \colon R)$ ***presented*** by the group presentation $(X \colon R)$ has the set of R-equivalence classes as its domain and class concatenation as its product operation. Moreover, any group G isomorphic to $\mathcal{G}(X \colon R)$ is said to be ***presented*** by the group presentation $(X \colon R)$.

The group G is ***finitely presentable*** if it has a presentation whose alphabet and relator set are both finite.

The ***commutator*** of the words u and v is the word $u^{-1}v^{-1}uv$. Any word of this form is called a commutator.

A ***conjugate*** of the word v is any word of the form $u^{-1}vu$.

Facts:

1. Max Dehn (1911) formulated three fundamental decision problems for finite presentations:

- *word problem*: Given an arbitrary presentation $(X \colon R)$ and an arbitrary word w, decide whether w is equivalent to the empty word (i.e., the group identity).
- *conjugacy problem*: Given an arbitrary presentation $(X \colon R)$ and two arbitrary words w_1 and w_2, decide whether w_1 is equivalent to a conjugate of w_2.

- *isomorphism problem*: Given two arbitrary presentations $(X\colon R)$ and $(Y\colon S)$, decide whether they present isomorphic groups.

2. W. W. Boone (1955) and P. S. Novikov (1955) constructed presentations in which the word problem is recursively unsolvable. This implies that there is no single finite procedure that works for all finite presentations, thereby negatively solving Dehn's word problem and conjugacy problem.

3. M. O. Rabin (1958) proved that it is impossible to decide even whether a presentation presents the trivial group, which immediately implies that Dehn's isomorphism problem is recursively unsolvable.

4. The word problem is recursively solvable in various special classes of group presentations, including the following: presentations with no relators (i.e., free groups), presentations with only one relator, presentations in which the relator set includes the commutator of each pair of generators (i.e., abelian groups).

5. The group presentation $\mathcal{G}(X\colon R)$ is the quotient of the free group $F[X]$ by the normalizer of the relator set R.

6. More information on group presentations can be found in [CoMo80], [CrFo08], and [MaKaSo04].

Examples:

1. The cyclic group $\mathcal{Z}_k$ has the presentation $(x\colon x^k)$.

2. The direct sum $\mathcal{Z}_r \oplus \mathcal{Z}_s$ has the presentation $(x, y\colon x^r, y^s, x^{-1}y^{-1}xy)$.

3. The dihedral group $\mathcal{D}_q$ has the presentation $(x, y\colon x^q, y^2, y^{-1}xyx)$.

5.3 PERMUTATION GROUPS

Permutations, as arrangements, are important tools used extensively in combinatorics (§2.3 and §2.7). The set of permutations on a given set forms a group, and it is this algebraic structure that is examined in this section.

5.3.1 BASIC CONCEPTS

Definitions:

A ***permutation*** is a one-to-one and onto function $\sigma\colon S \to S$, where S is any nonempty set. If $S = \{a_1, a_2, \ldots, a_n\}$, a permutation σ is sometimes written as the $2 \times n$ matrix

$$\sigma = \begin{pmatrix} a_1 & a_2 & \ldots & a_n \\ a_1\sigma & a_2\sigma & \ldots & a_n\sigma \end{pmatrix}$$

where $a_i\sigma$ means $\sigma(a_i)$.

A permutation $\sigma\colon S \to S$ is a ***cycle of length n*** if there is a subset of S of size n, $\{a_1, a_2, \ldots, a_n\}$, such that $a_1\sigma = a_2, a_2\sigma = a_3, \ldots, a_n\sigma = a_1$, and $a\sigma = a$ for all other elements of S. Write $\sigma = (a_1\ a_2\ \ldots\ a_n)$. A ***transposition*** is a cycle of length 2.

A ***permutation group*** (G, X) is a collection G of permutations on a nonempty set X (whose elements are called *objects*) such that these permutations form a group under composition. That is, if σ and τ are permutations in G, $\sigma\tau$ is the permutation in G defined by the rule $a(\sigma\tau) = (a\sigma)\tau$. The ***order*** of the permutation group is $|G|$. The ***degree*** of the permutation group is $|X|$.

The ***symmetric group on n elements*** is the group S_n of all permutations on the set $\{1, 2, \ldots, n\}$ under composition. (See Fact 1.)

An ***isomorphism*** from a permutation group (G, X) to a permutation group (H, Y) is a pair of functions $(\alpha\colon G \to H,\ f\colon X \to Y)$ such that α is a group isomorphism and f is one-to-one and onto Y.

If $\sigma_1 = (a_{i_1}\ a_{i_2}\ \ldots\ a_{i_m})$ and $\sigma_2 = (a_{j_1}\ a_{j_2}\ \ldots\ a_{j_n})$ are cycles on S, then σ_1 and σ_2 are ***disjoint cycles*** if the sets $\{a_{i_1}, a_{i_2}, \ldots, a_{i_m}\}$ and $\{a_{j_1}, a_{j_2}, \ldots, a_{j_n}\}$ are disjoint.

An ***even permutation*** [***odd permutation***] is a permutation that can be written as a product of an even [odd] number of transpositions.

The ***sign*** of a permutation (where the permutation is written as a product of transpositions) is $+1$ if it has an even number of transpositions and -1 if it has an odd number of transpositions.

The ***identity permutation*** on S is the permutation $\iota\colon S \to S$ such that $x\iota = x$ for all $x \in S$.

An ***involution*** is a permutation σ such that $\sigma^2 = \iota$ (the identity permutation).

The ***orbit*** of $a \in S$ under σ is the set $\{\ldots, a\sigma^{-2}, a\sigma^{-1}, a, a\sigma, a\sigma^2, \ldots\}$.

Facts:

1. *Symmetric group of degree n*: The set of permutations on a nonempty set X is a group, where the group operation is composition of permutations: $\sigma_1\sigma_2$ is defined by $x(\sigma_1\sigma_2) = (x\sigma_1)\sigma_2$. The identity is the identity permutation ι. The inverse of σ is the permutation σ^{-1}, where $x\sigma^{-1} = y$ if and only if $y\sigma = x$. If $|X| = n$, the group of permutations is written S_n, the *symmetric group of degree n*.

2. Multiplication of permutations is not commutative. (See Examples 1 and 4.)

3. A permutation π is an involution if and only if $\pi = \pi^{-1}$.

4. The number of involutions in S_n, denoted $\mathrm{inv}(n)$, is equal to the number of Young tableaux that can be formed from the set $\{1, 2, \ldots, n\}$. (See §2.8.)

5. Permutations can be used to find determinants of matrices. (See §6.3.)

6. Every permutation on a finite set can be written as a product of disjoint cycles.

7. Cycle notation is not unique: for example, $(1\ 4\ 7\ 5) = (4\ 7\ 5\ 1) = (7\ 5\ 1\ 4) = (5\ 1\ 4\ 7)$.

8. Every permutation is either even or odd, and no permutation is both even and odd. Hence, every permutation has a unique sign.

9. Each cycle of length k can be written as a product of $k-1$ transpositions:

$$(x_1\ x_2\ x_3\ \ldots\ x_k) = (x_1\ x_2)(x_1\ x_3)(x_1\ x_4)\ldots(x_1\ x_k).$$

10. S_n has order $n!$.

11. S_n is not abelian for $n \geq 3$. For example, $(1\ 2)(1\ 3) \neq (1\ 3)(1\ 2)$.

12. The order of a permutation that is a single cycle is the length of the cycle. For example, $(1\ 5\ 4)$ has order 3.

13. The order of a permutation that is written as a product of disjoint cycles is equal to the least common multiple of the lengths of the cycles.

14. *Cayley's theorem*: If G is a finite group of order n, then G is isomorphic to a subgroup of S_n. (See §5.2.2.)

15. Let G be a group of permutations on a set X (such a group is said to *act on* X). Then G induces an equivalence relation R on the set X by the following rule: for $a, b \in X$, aRb if and only if there is a permutation $\sigma \in G$ such that $a\sigma = b$.

Examples:

1. If $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 1 & 2 & 4 & 3 \end{pmatrix}$, $\tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 5 & 1 & 3 & 2 \end{pmatrix}$, then $\sigma\tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 4 & 5 & 3 & 1 \end{pmatrix}$ and $\tau\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 3 & 5 & 2 & 1 \end{pmatrix}$. Note that $\sigma\tau \neq \tau\sigma$.

2. All elements of S_n can be written in *cycle notation*. For example,

$$\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 4 & 6 & 3 & 7 & 1 & 2 & 5 \end{pmatrix} = (1\ 4\ 7\ 5)(2\ 6)(3).$$

Each cycle describes the orbit of the elements in that cycle. For example, $(1\ 4\ 7\ 5)$ is a cycle of length 4, and indicates that $1\sigma = 4$, $4\sigma = 7$, $7\sigma = 5$, and $5\sigma = 1$. The cycle (3) indicates that $3\sigma = 3$. If a cycle has length 1, that cycle can be omitted when a permutation is written as a product of cycles: $(1\ 4\ 7\ 5)(2\ 6)(3) = (1\ 4\ 7\ 5)(2\ 6)$.

3. Multiplication of permutations written in cycle notation can be performed easily. For example: if $\sigma = (1\,5\,3\,2)$ and $\tau = (1\,4\,3)(2\,5)$, then $\sigma\tau = (1\,5\,3\,2)(1\,4\,3)(2\,5) = (1\,2\,4\,3\,5)$. (Moving from left to right through the product of cycles, trace the orbit of each element. For example, $3\sigma = 2$ and $2\tau = 5$; therefore $3\sigma\tau = 5$.)

4. Multiplication of cycles need not be commutative. For example, $(1\ 2)(1\ 3) = (1\ 2\ 3)$, $(1\ 3)(1\ 2) = (1\ 3\ 2)$, but $(1\ 2\ 3) \neq (1\ 3\ 2)$. However, disjoint cycles commute.

5. If the group of permutations $G = \{\iota, (1\ 2), (3\ 5)\}$ acts on the set $S = \{1, 2, 3, 4, 5\}$, then the partition of S resulting from the equivalence relation induced by G is $\{\{1, 2\}$, $\{3, 5\}$, $\{4\}\}$. (See Fact 15.)

6. Let group $G = \{\iota, (1\ 2)\}$ act on $X = \{1, 2\}$ and group $H = \{\iota, (1\ 2)(3)\}$ act on $Y = \{1, 2, 3\}$. The permutation groups (G, X) and (H, Y) are not isomorphic since there is no bijection between X and Y (even though G and H are isomorphic groups).

5.3.2 EXAMPLES OF PERMUTATION GROUPS

Definitions:

The ***alternating group*** on n elements ($n \geq 2$) is the subgroup A_n of S_n consisting of all even permutations.

The ***dihedral group*** (***octic group***) D_n is the group of rigid motions (rotations and reflections) of a regular polygon with n sides under composition.

The ***Klein four-group*** (or ***Viergruppe*** or the ***group of the rectangle***) is the group under composition of the four rigid motions of a rectangle that leave the rectangle in its original location. (Felix Klein, 1849–1925)

Given a permutation $\sigma\colon S \to S$, the ***induced pair permutation*** is the permutation $\sigma^{(2)}$ on unordered pairs of elements of S given by the rule $\sigma^{(2)}(\{x,y\}) = \{\sigma(x), \sigma(y)\}$.

Given a permutation group G acting on a set S, the ***induced pair-action group*** $G^{(2)}$ is the group of induced pair-permutations $\{\sigma^{(2)} \mid \sigma \in G\}$ under composition.

Given a permutation $\sigma\colon S \to S$, the ***ordered pair-permutation*** is the permutation $\sigma^{[2]}$ on the set $S \times S$ given by the rule $\sigma^{[2]}((x,y)) = (\sigma(x), \sigma(y))$.

Given a permutation group G acting on a set S, the ***ordered pair-action group*** $G^{[2]}$ is the group of ordered pair-permutations $\{\sigma^{[2]} \mid \sigma \in G\}$ under composition.

Facts:

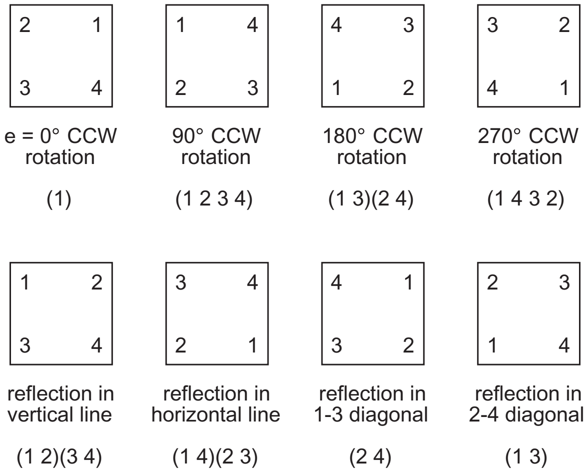
1. Some common subgroups of S_n are listed in the following table.

subgroup	*order*	*description*
symmetric group S_n	$n!$	all permutations of $\{1, 2, \ldots, n\}$
alternating group A_n	$n!/2$	all even permutations of $\{1, 2, \ldots, n\}$
dihedral group D_n	$2n$	rigid motions of regular n-gon in 3-dimensional space (Example 2)
Klein 4-group (subgroup of S_4)	4	rigid motions of rectangle in 3-dimensional space (Example 3)
identity	1	consists only of identity permutation

2. The group A_n is abelian if $n = 2$ or 3, and is nonabelian if $n \geq 4$.

3. The group D_n has order $2n$. The elements consist of the n rotations and n reflections of a regular polygon with n sides. The n rotations are the counterclockwise rotations about the center through angles of $\frac{360k}{n}$ degrees ($k = 0, 1, \ldots, n-1$). (Clockwise rotations can be written in terms of counterclockwise rotations.) If n is odd, the n reflections are reflections in lines through a vertex and the center; if n is even, the reflections are reflections in lines joining opposite vertices and in lines joining midpoints of opposite sides.

4. The elements of D_n can be written as permutations of $\{1, 2, \ldots, n\}$. See the following figure for the rigid motions in D_4 (the rigid motions of the square) and the following table for the group multiplication table for D_4.



e = 0° CCW rotation (1)

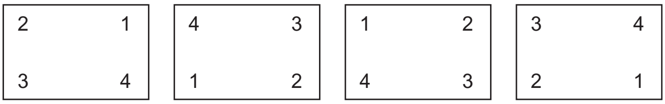
5. The Klein four-group consists of the following four rigid motions of a rectangle: the rotations about the center through 0° or 180°, and reflections through the horizontal or vertical lines through its center, as illustrated in the following figure. The following table is the multiplication table for the Klein four-group.



e = 0° CCW rotation

(14)(23)	(14)(23)	(12)(34)	(13)(24)	(1)

6. The Klein four-group is isomorphic to $\mathcal{Z}_8^*$.

7. The induced permutation group $S_n^{(2)}$ and the ordered-pair-action group $S_n^{[2]}$ are used in enumerative graph theory. (See §8.9.2.)

8. The induced permutation group $S_n^{(2)}$ has $\binom{n}{2}$ objects and $n!$ permutations.

9. The ordered-pair-action permutation group $S_n^{[2]}$ has n^2 objects and $n!$ permutations.

5.4 RINGS

5.4.1 BASIC CONCEPTS

Definitions:

A ***ring*** $(R, +, \cdot)$ consists of a set R closed under binary operations $+$ and $\cdot$ such that

- $(R, +)$ is an abelian group; i.e., $(R, +)$ satisfies

  - *associative property*: $a + (b + c) = (a + b) + c$ for all $a, b, c \in R$;
  - *identity property*: R has an *identity element* 0 that satisfies $0+a = a+0 = a$ for all $a \in R$;
  - *inverse property*: for each $a \in R$ there is an *additive inverse element* $-a \in R$ (the *negative* of a) such that $-a + a = a + (-a) = 0$;
  - *commutative law*: $a + b = b + a$ for all $a, b \in R$;
- the operation $\cdot$ is *associative*: $a \cdot (b \cdot c) = (a \cdot b) \cdot c$ for all $a, b, c \in R$;
- The *distributive properties* for multiplication over addition hold for all $a, b, c \in R$:
  - *left distributive property*: $a \cdot (b + c) = a \cdot b + a \cdot c$;
  - *right distributive property*: $(a + b) \cdot c = a \cdot c + b \cdot c$.

A ring R is ***commutative*** if the multiplication operation is commutative: $a \cdot b = b \cdot a$ for all $a, b \in R$.

A ring R is a ***ring with unity*** if there is an identity 1 ($\neq 0$) for multiplication; i.e., $1 \cdot a = a \cdot 1 = a$ for all $a \in R$. The multiplicative identity is the ***unity*** of R.

An element x in a ring R with unity is a ***unit*** if x has a multiplicative inverse; i.e., there is $x^{-1} \in R$ such that $x \cdot x^{-1} = x^{-1} \cdot x = 1$.

Subtraction in a ring is defined by the rule $a - b = a + (-b)$.

Facts:

1. Multiplication $a \cdot b$ is often written ab or $a \times b$.

2. The order of precedence of operations in a ring follows that for real numbers: multiplication is to be done before addition. That is, $a+bc$ means $a+(bc)$ rather than $(a+b)c$.

3. In all rings, $a0 = 0a = 0$.

4. *Properties of subtraction*:

$$-(-a) = a \qquad (-a)(-b) = ab \qquad a(b - c) = ab - ac \qquad (a - b)c = ac - bc$$

$$a(-b) = (-a)b = -(ab) \qquad (-1)a = -a \text{ (if the ring has unity).}$$

5. The set of all units of a ring is a group under the multiplication defined on the ring.

Examples:

1. The following table gives several examples of rings, together with their associated identity and unity elements.

set and addition and multiplication operations	0	1
$\{0\}$, usual addition and multiplication; (*trivial ring*)	0	none
$\mathcal{Z}$, $\mathcal{Q}$, $\mathcal{R}$, $\mathcal{C}$, with usual + and $\cdot$	0	1
$\mathcal{Z}_n$=$\{0, 1, \ldots, n-1\}$ (n a positive integer), a+b = (a+b) **mod** n, $a{\cdot}b$ = (ab) **mod** n; (*modular ring*)	0	1
$\mathcal{Z}[\sqrt{2}]$=$\{a+b\sqrt{2} \mid a, b \in \mathcal{Z}\}$, $(a+b\sqrt{2})+(c+d\sqrt{2})$= $(a+c)+(b+d)\sqrt{2}$, $(a+b\sqrt{2}){\cdot}(c+d\sqrt{2})$=$(ac+2bd)+$ $(ad+bc)\sqrt{2}$ [Similar rings can be constructed using $\sqrt{n}$ (n an integer) if $\sqrt{n}$ not an integer.]	$0+0\sqrt{2}$	$1+0\sqrt{2}$
$\mathcal{Z}[i] = \{a + bi \mid a, b \in \mathcal{Z}\}$; (*Gaussian integers*; see §5.4.2, Example 2.)	$0+0i$	$1+0i$

set and addition and multiplication operations	0	1
$\mathcal{M}_{n\times n}(R)$ = all $n \times n$ matrices with entries in a ring R with unity, matrix addition and multiplication; (*matrix ring*)	O_n (zero matrix)	I_n (identity matrix)
$R = \{f \mid f\colon A{\to}B\}$ (A any nonempty set and B any ring), $(f{+}g)(x) = f(x){+}g(x)$, $(f{\cdot}g)(x) = f(x){\cdot}g(x)$; (*ring of functions*)	f such that $f(x){=}0$ for all $x{\in}A$	f such that $f(x){=}1$ for all $x{\in}A$ (if B has unity)
$\mathcal{P}(S)$ = all subsets of a set S, $A{+}B = A\Delta B = (A{\cup}B) - (A{\cap}B)$ (*symmetric difference*), $A{\cdot}B = A{\cap}B$; (*Boolean ring*)	$\emptyset$	S
$\{a{+}bi{+}cj{+}dk \mid a,\ b,\ c,\ d \in \mathcal{R}\}$, i, j, k in quaternion group, elements are added and multiplied like polynomials using $ij = k$, etc.; (*ring of real quaternions*, §5.2.1)	$0{+}0i{+}0j{+}0k$	$1{+}0i{+}0l{+}0k$

2. *Polynomial rings*: For a ring R, the set

$$R[x] = \{a_nx^n + \cdots + a_1x + a_0 \mid a_0, a_1, \ldots, a_n \in R\}$$

forms a ring, where the elements are added and multiplied using the "usual" rules for addition and multiplication of polynomials. The additive identity 0 is the constant polynomial $p(x) = 0$; the unity is the constant polynomial $p(x) = 1$ if R has a unity 1. (See §5.5.)

3. *Product rings*: For rings R and S, the set $R \times S = \{(r, s) \mid r \in R, s \in S\}$ forms a ring, where

$$(r_1, s_1) + (r_2, s_2) = (r_1 + r_2, s_1 + s_2);$$
$$(r_1, s_1) \cdot (r_2, s_2) = (r_1r_2, s_1s_2).$$

The additive identity is $(0, 0)$. Unity is $(1, 1)$ if R and S each have unity 1. Product rings can have more than two factors: $R_1 \times R_2 \times \cdots \times R_k$ or $R^n = R \times \cdots \times R$.

5.4.2 SUBRINGS AND IDEALS

Definitions:

A subset S of a ring $(R, +, \cdot)$ is a ***subring*** of R if $(S, +, \cdot)$ is a ring using the same operations $+$ and $\cdot$ that are used in R.

A subset I of a ring $(R, +, \cdot)$ is an ***ideal*** of R if

- $(I, +, \cdot)$ is a subring of $(R, +, \cdot)$;
- I is closed under left and right multiplication by elements of R: if $x \in I$ and $r \in R$, then $rx \in I$ and $xr \in I$.

In a commutative ring R, an ideal I is ***principal*** if there is $r \in R$ such that $I = Rr = \{xr \mid x \in R\}$. I is the ***principal ideal generated by*** r, written $I = (r)$.

In a commutative ring R, an ideal $I \neq R$ is ***maximal*** if the only ideal properly containing I is R.

In a commutative ring R, an ideal $I \neq R$ is ***prime*** if $ab \in I$ implies that $a \in I$ or $b \in I$.

Facts:

1. If S is a nonempty subset of a ring $(R, +, \cdot)$, then S is a subring of R if and only if S is closed under subtraction and multiplication.

2. An ideal in a ring $(R, +, \cdot)$ is a subgroup of the group $(R, +)$, but not necessarily conversely.

3. The intersection of ideals in a ring is an ideal.

4. If R is any ring, then R and $\{0\}$ are ideals, called *trivial* ideals.

5. In a commutative ring with unity, every maximal ideal is a prime ideal.

6. Every ideal I in the ring $\mathcal{Z}$ is a principal ideal. $I = (r)$ where r is the smallest positive integer in I.

7. If R is a commutative ring with unity, then R is a field (see §5.6) if and only if the only ideals of R are R and $\{0\}$.

8. An ideal in a ring is the analogue of a normal subgroup in a group.

9. The second condition in the definition of ideal can be stated as $rI \subseteq I$ (I is a *left ideal*) and $Ir \subseteq I$ (I is a *right ideal*). (If A is a subset of a ring R and $r \in R$, then $rA = \{ra \mid a \in A\}$ and $Ar = \{ar \mid a \in A\}$.)

Examples:

1. With the usual definitions of + and $\cdot$, each of the following rings can be viewed as a subring of all the rings listed after it: $\mathcal{Z}$, $\mathcal{Q}$, $\mathcal{R}$, $\mathcal{C}$.

2. *Gaussian integers*: $\mathcal{Z}[i] = \{a + bi \mid a, b \in \mathcal{Z}\}$ using the addition and multiplication of $\mathcal{C}$ is a subring of the ring of complex numbers.

3. The ring $\mathcal{Z}$ is a subring of $\mathcal{Z}[\sqrt{2}]$ and $\mathcal{Z}[\sqrt{2}]$ is a subring of $\mathcal{R}$.

4. Each set $n\mathcal{Z}$ (n an integer) is a principal ideal in the ring $\mathcal{Z}$.

5.4.3 RING HOMOMORPHISM AND ISOMORPHISM

Definitions:

If R and S are rings, a function $\varphi\colon R \to S$ is a ***ring homomorphism*** if for all $a, b \in R$

- $\varphi(a + b) = \varphi(a) + \varphi(b)$ (φ preserves addition)
- $\varphi(ab) = \varphi(a)\varphi(b)$. ($\varphi$ preserves multiplication)

Note: $\varphi(a)$ is sometimes written $a\varphi$.

If a ring homomorphism φ is also one-to-one and onto S, then φ is a ***ring isomorphism*** and R and S are ***isomorphic***, written $R \cong S$.

A ***ring endomorphism*** is a ring homomorphism $\varphi\colon R \to R$.

A ***ring automorphism*** is a ring isomorphism $\varphi\colon R \to R$.

The ***kernel*** of a ring homomorphism $\varphi\colon R \to S$ is $\varphi^{-1}(0) = \{x \in R \mid \varphi(x) = 0\}$.

Facts:

1. If φ is a ring isomorphism, then φ^{-1} is a ring isomorphism.

2. The kernel of a ring homomorphism from R to S is an ideal of the ring R.

3. If $\varphi\colon R \to S$ is a ring homomorphism, then $\varphi(R)$ is a subring of S.

4. If $\varphi\colon R \to S$ is a ring homomorphism and R has unity, then either $\varphi(1) = 0$ or $\varphi(1)$ is unity for $\varphi(R)$.

5. If φ is a ring homomorphism, then $\varphi(0) = 0$ and $\varphi(-a) = -\varphi(a)$.

6. A ring homomorphism is a ring isomorphism between R and $\varphi(R)$ if and only if the kernel of φ is $\{0\}$.

7. *Homomorphisms preserve subrings*: Let $\varphi\colon R \to S$ be a ring homomorphism. If A is a subring of R, then $\varphi(A)$ is a subring of S. If B is a subring of S, then $\varphi^{-1}(B)$ is a subring of R.

8. *Homomorphisms preserve ideals*: Let $\varphi\colon R \to S$ be a ring homomorphism. If A is an ideal of R, then $\varphi(A)$ is an ideal of S. If B is an ideal of S, then $\varphi^{-1}(B)$ is an ideal of R.

Examples:

1. The function $\varphi\colon \mathcal{Z} \to \mathcal{Z}_n$ defined by the rule $\varphi(a) = a \ \mathbf{mod}\ n$ is a ring homomorphism.

2. If R and S are rings, then the function $\varphi\colon R \to S$ defined by the rule $\varphi(a) = 0$ for all $a \in R$ is a ring homomorphism.

3. The function $\varphi\colon \mathcal{Z} \to R$ (R any ring with unity) defined by the rule $\varphi(x) = x \cdot 1$ is a ring homomorphism. The kernel of φ is the subring $n\mathcal{Z}$ for some nonnegative integer n, called the *characteristic* of R.

4. Let $\mathcal{P}(S)$ be the ring of all subsets of a set S (see §5.4.1). If $|S| = 1$, then $\mathcal{P}(S) \cong \mathcal{Z}_2$ with the ring isomorphism φ where $\varphi(\emptyset) = 0$ and $\varphi(S) = 1$. More generally, if $|S| = n$, then $\mathcal{P}(S) \cong \mathcal{Z}_2^n = \mathcal{Z}_2 \times \cdots \times \mathcal{Z}_2$.

5. $\mathcal{Z}_n \cong \mathcal{Z}/(n)$ for all positive integers n. (See §5.4.4.)

6. $\mathcal{Z}_m \times \mathcal{Z}_n \cong \mathcal{Z}_{mn}$, if m and n are relatively prime.

5.4.4 QUOTIENT RINGS

Definitions:

If I is an ideal in a ring R and $a \in R$, then the set $a + I = \{a + x \mid x \in I\}$ is a ***coset*** of I in R.

The set of all cosets, $R/I = \{a + I \mid a \in R\}$, is a ring, called the ***quotient ring***, where addition and multiplication are defined by the following rules:

- $(a + I) + (b + I) = (a + b) + I$;
- $(a + I) \cdot (b + I) = (ab) + I$.

Facts:

1. If R is commutative, then R/I is commutative.

2. If R has unity 1, then R/I has the coset $1 + I$ as unity.

3. If I is an ideal in ring R, the function $\varphi\colon R \to R/I$ defined by the rule $\varphi(x) = x + I$ is a ring homomorphism, called the *natural map*. The kernel of φ is I.

4. *Fundamental homomorphism theorem!for rings*: If φ is a ring homomorphism and K is the kernel of φ, then $\varphi(R) \cong R/K$.

5. If R is a commutative ring with unity and I is an ideal in R, then I is a maximal ideal if and only if R/I is a field (see §5.6).

Examples:

1. For each integer n, $\mathcal{Z}/n\mathcal{Z}$ is a quotient ring, isomorphic to $\mathcal{Z}_n$.

2. See §5.6.1 for Galois rings.

5.4.5 RINGS WITH ADDITIONAL PROPERTIES

Beginning with rings, as additional requirements are added, the following hierarchy of sets of algebraic structures is obtained:

rings $\supset$ commutative rings with unity $\supset$ integral domains $\supset$ Euclidean domains $\supset$ principal ideal domains

Definitions:

The ***cancellation properties*** in a ring R state that for all $a, b, c \in R$

if $ab = ac$ and $a \neq 0$, then $b = c$ (*left cancellation property*)
if $ba = ca$ and $a \neq 0$, then $b = c$ (*right cancellation property*).

Let R be a ring and let $a, b \in R$ where $a \neq 0, b \neq 0$. If $ab = 0$, then a is a ***left divisor of zero*** and b is a ***right divisor of zero***.

An ***integral domain*** is a commutative ring with unity that has no zero divisors.

A ***principal ideal domain*** (***PID***) is an integral domain in which every ideal is a principal ideal.

A ***division ring*** is a ring with unity in which every nonzero element is a unit (i.e., every nonzero element has a multiplicative inverse).

A ***field*** is a commutative ring with unity such that each nonzero element has a multiplicative inverse. (See §5.6.)

A ***Euclidean norm*** on an integral domain R is a function $\delta\colon R - \{0\} \to \{0, 1, 2, \ldots\}$ such that

- $\delta(a) \leq \delta(ab)$ for all $a, b \in R - \{0\}$;
- the following generalization of the division algorithm for integers holds: for all $a, d \in R$ where $d \neq 0$, there are elements q, $r \in R$ such that $a = dq + r$, where either $r = 0$ or $\delta(r) < \delta(d)$.

A ***Euclidean domain*** is an integral domain with a Euclidean norm defined on it.

Facts:

1. The cancellation properties hold in an integral domain.

2. Every finite integral domain is a field.

3. Every integral domain can be imbedded in a field. Given an integral domain R, there is a field F and a ring homomorphism $\varphi\colon R \to F$ such that $\varphi(1) = 1$.

4. A ring with unity is a division ring if and only if the nonzero elements form a group under the multiplication defined on the ring.

5. *Wedderburn's theorem*: Every finite division ring is a field. (J. H. M. Wedderburn, 1882–1948)

6. Every commutative division ring is a field.

7. In a Euclidean domain, if $b \neq 0$ is not a unit, then $\delta(ab) > \delta(a)$ for all $a \neq 0$. For $b \neq 0$, b is a unit in R if and only if $\delta(b) = \delta(1)$.

8. In every Euclidean domain, a Euclidean algorithm for finding the gcd can be carried out.

Examples:

1. Some common Euclidean domains are given in the following table.

set	*Euclidean norm*
$\mathcal{Z}$	$\delta(a) = \lvert a \rvert$
$\mathcal{Z}[i]$ (Gaussian integers)	$\delta(a+bi) = a^2 + b^2$
F (any field)	$\delta(a) = 1$
polynomial ring $F[x]$ (F any field)	$\delta(p(x)) =$ degree of $p(x)$

2. The following table gives examples of rings with additional properties.

ring	*commutative ring with unity*	*integral domain*	*principal ideal domain*	*Euclidean domain*	*division ring*	*field*
$\mathcal{Z}$	yes	yes	yes	yes	no	no
$\mathcal{Q}$, $\mathcal{R}$, $\mathcal{C}$	yes	yes	yes	yes	yes	yes
$\mathcal{Z}_p$ (p prime)	yes	yes	yes	yes	yes	yes
$\mathcal{Z}_n$ (n composite)	yes	no	no	no	no	no
real quaternions	no	no	no	no	yes	no
$\mathcal{Z}[x]$	yes	no	no	no	no	no
$\mathcal{M}_{n\times n}$	no	no	no	no	no	no

5.5 POLYNOMIAL RINGS

5.5.1 BASIC CONCEPTS

Definitions:

A ***polynomial in the variable x over a ring R*** is an expression of the form

$$f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x^1 + a_0 x^0$$

where $a_n, \ldots, a_0 \in R$.

For a polynomial $f(x) \neq 0$, the largest integer k such that $a_k \neq 0$ is the ***degree*** of $f(x)$, written $\deg f(x)$.

A ***constant polynomial*** is a polynomial $f(x) = a_0$. If $a_0 \neq 0$, $f(x)$ has degree 0. If $f(x) = 0$ (the ***zero polynomial***), the degree of $f(x)$ is undefined. (The degree of the zero polynomial is also said to be $-\infty$.)

The ***polynomial ring*** (in one variable x) over a ring R consists of the set

$$R[x] = \{f(x) \mid f(x) \text{ is a polynomial over } R \text{ in the variable } x\}$$

with addition and multiplication defined by the following rules:

- $(a_nx^n + \cdots + a_1x^1 + a_0x^0) + (b_mx^m + \cdots + b_1x^1 + b_0x^0)$
  $= a_nx^n + \cdots + a_{m+1}x^{m+1} + (a_n + b_n)x^n + \cdots + (a_1 + b_1)x^1 + (a_0 + b_0)x^0$
  if $n \geq m$, and
- $(a_nx^n + \cdots + a_1x^1 + a_0x^0)(b_mx^m + \cdots + b_1x^1 + b_0x^0)$
  $= c_{n+m}x^{n+m} + \cdots + c_1x^1 + c_0x^0$
  where $c_i = a_0b_i + a_1b_{i-1} + \cdots + a_ib_0$ for $i = 0, 1, \ldots, m + n$.

A polynomial $f(x) \in R[x]$ of degree n is ***monic*** if $a_n = 1$.

The ***value*** of a polynomial $f(x) = a_nx^n + a_{n-1}x^{n-1} + \cdots + a_1x^1 + a_0x^0$ at $c \in R$ is the element $f(c) = a_nc^n + a_{n-1}c^{n-1} + \cdots + a_1c + a_0 \in R$.

An element $c \in R$ is a ***zero*** of the polynomial $f(x)$ if $f(c) = 0$.

If R is a subring of a commutative ring S, an element $a \in S$ is ***algebraic*** over R if there is a nonzero $f(x) \in R[x]$ such that $f(a) = 0$.

If $p(x)$ is not algebraic over R, then $p(x)$ is ***transcendental*** over R.

A polynomial $f(x) \in R[x]$ of degree n is ***irreducible*** over R if $f(x)$ cannot be written as $f_1(x)f_2(x)$ (***factors*** of $f(x)$) where $f_1(x)$ and $f_2(x)$ are polynomials over R of degrees less than n. Otherwise $f(x)$ is ***reducible*** over R.

The ***polynomial ring*** (in the variables $x_1, x_2, \ldots, x_n$ with $n > 1$) over a ring R is defined by the rule $R[x_1, x_2, \ldots, x_n] = (R[x_1, x_2, \ldots, x_{n-1}])[x_n]$.

Facts:

1. Polynomials over an arbitrary ring R generalize polynomials with coefficients in $\mathcal{R}$ or $\mathcal{C}$. The notation and terminology follow the usual conventions for polynomials with real (or complex) coefficients:

- the elements $a_n, \ldots, a_0$ are *coefficients*;
- subtraction notation can be used: $a_ix^i + (-a_j)x^j = a_ix^i - a_jx^j$;
- the term $1x^i$ can be written as x^i;
- the term x^1 can be written x;
- the term x^0 can be written 1;
- terms $0x^i$ can be omitted.

2. There is a distinction between a polynomial $f(x) \in R[x]$ and the function it defines using the rule $f(c) = a_nc^n + a_{n-1}c^{n-1} + \cdots + a_1c + a_0$ for $c \in R$. The same function might be defined by infinitely many polynomials. For example, the polynomials $f_1(x) = x \in \mathcal{Z}_2[x]$ and $f_2(x) = x^2 \in \mathcal{Z}_2[x]$ define the same function: $f_1(0) = f_2(0) = 0$ and $f_1(1) = f_2(1) = 1$.

3. If R is a ring, $R[x]$ is a ring.

4. If R is a commutative ring, then $R[x]$ is a commutative ring.

5. If R is a ring with unity, then $R[x]$ has the constant polynomial $f(x) = 1$ as unity.

6. If R is an integral domain, then $R[x]$ is an integral domain. If $f_1(x)$ has degree m and $f_2(x)$ has degree n, then the degree of $f_1(x)f_2(x)$ is $m + n$.

7. If ring R is not an integral domain, then $R[x]$ is not an integral domain. If $f_1(x)$ has degree m and $f_2(x)$ has degree n, then the degree of $f_1(x)f_2(x)$ can be smaller than $m + n$. (For example, in $\mathcal{Z}_6[x]$, $(3x^2)(2x^3) = 0$.)

8. *Factor theorem*: If R is a commutative ring with unity and $f(x) \in R[x]$ has degree ≥ 1, then $f(a) = 0$ if and only if $x - a$ is a factor of $f(x)$.

9. If R is an integral domain and $p(x) \in R[x]$ has degree n, then $p(x)$ has at most n zeros in R. If R is not an integral domain, then a polynomial may have more zeros than its degree; for example, $x^2 + x \in \mathcal{Z}_6[x]$ has four zeros — $0, 2, 3, 5$.

5.5.2 POLYNOMIALS OVER A FIELD

Facts:

1. Even though F is a field (§5.6.1), $F[x]$ is never a field. (The polynomial $f(x) = x$ has no multiplicative inverse in $F[x]$.)

2. If $f(x)$ has degree n, then $f(x)$ has at most n distinct zeros.

3. *Irreducibility over a finite field*: If F is a finite field and n is a positive integer, then there is an irreducible polynomial over F of degree n.

4. *Unique factorization theorem*: If $f(x)$ is a polynomial over a field F and is not the zero polynomial, then $f(x)$ can be uniquely factored (ignoring the order in which the factors are written) as $af_1(x) \cdots f_k(x)$ where $a \in F$ and each $f_i(x)$ is a monic polynomial that is irreducible over F.

5. *Eisenstein's irreducibility criterion*: If $f(x) \in \mathcal{Z}[x]$ has degree $n > 0$, if there is a prime p such that p divides every coefficient of $f(x)$ except a_n, and if p^2 does not divide a_0, then $f(x)$ is irreducible over $\mathcal{Q}$. (Gotthold Eisenstein, 1823–1852)

6. *Division algorithm for polynomials*: If F is a field with $a(x)$, $d(x) \in F[x]$ and $d(x)$ is not the zero polynomial, then there are unique polynomials $q(x)$ (*quotient*) and $r(x)$ (*remainder*) in $F[x]$ such that $a(x) = d(x)q(x) + r(x)$ where $\deg r(x) < \deg d(x)$ or $r(x) = 0$. If $d(x)$ is monic, then the division algorithm for polynomials can be extended to all rings with unity.

7. *Irreducibility over the real numbers $\mathcal{R}$*: If $f(x) \in \mathcal{R}[x]$ has degree at least 3, then $f(x)$ is reducible. The only irreducible polynomials in $\mathcal{R}[x]$ are of degree 1 or 2; for example $x^2 + 1$ is irreducible over $\mathcal{R}$.

8. *Fundamental theorem of algebra* (*irreducibility over the complex numbers $\mathcal{C}$*): If $f(x) \in \mathcal{C}[x]$ has degree $n \geq 1$, then $f(x)$ can be completely factored:

$$f(x) = c(x - c_1)(x - c_2) \ldots (x - c_n)$$

where $c, c_1, \ldots, c_n \in \mathcal{C}$.

9. If F is a field and $f(x) \in F[x]$ has degree 1 (i.e., $f(x)$ is linear), then $f(x)$ is irreducible.

10. If F is a field and $f(x) \in F[x]$ has degree ≥ 2 and has a zero, then $f(x)$ is reducible. (If $f(x)$ has a as a zero, then $f(x)$ can be written as $(x-a)f_1(x)$ where $\deg f_1(x) = \deg f(x) - 1$.) The converse is false: a polynomial may have no zeros, but still be reducible. (See Example 2.)

11. If F is a field and $f(x) \in F[x]$ has degree 2 or 3, then $f(x)$ is irreducible if and only if $f(x)$ has no zeros.

Examples:

1. In $\mathcal{Z}_5[x]$, if $a(x) = 3x^4 + 2x^3 + 2x + 1$ and $d(x) = x^2 + 2$, then $q(x) = 3x^2 + 2x + 4$ and $r(x) = 3x + 3$. To obtain $q(x)$ and $r(x)$, use the same format as for long division of natural numbers, with arithmetic operations carried out in $\mathcal{Z}_5$:

$$
\begin{array}{rrl}
 & \underline{3x^2 + 2x + 4 \qquad\qquad\quad} & \\
x^2+2\big) & 3x^4 + 2x^3 + 0x^2 + 2x + 1 & \\
 & \underline{3x^4 \qquad\quad + x^2 \qquad\qquad\quad} & \\
 & 2x^3 + 4x^2 \qquad\qquad\quad & [-x^2 = 4x^2 \text{ over } \mathcal{Z}_5] \\
 & \underline{2x^3 \qquad + 4x \qquad} & \\
 & 4x^2 + 3x \qquad & [2x - 4x = -2x = 3x \text{ over } \mathcal{Z}_5] \\
 & \underline{4x^2 \qquad + 3} & \\
 & 3x + 3 &
\end{array}
$$

2. Polynomials can have no zeros, but be reducible. The polynomial $f(x) = x^4 + x^2 + 1 \in Z_2[x]$ has no zeros (since $f(0) = f(1) = 1$), but $f(x)$ can be factored as $(x^2 + x + 1)^2$. Similarly, $x^4 + 2x^2 + 1 = (x^2+1)^2 \in \mathcal{R}[x]$.

5.6 FIELDS

5.6.1 BASIC CONCEPTS

Definitions:

A ***field*** $(F, +, \cdot)$ consists of a set F together with two binary operations, $+$ and $\cdot$, such that

- $(F, +, \cdot)$ is a ring;
- $(F - \{0\}, \cdot)$ is a commutative group.

A ***subfield*** F of field $(K, +, \cdot)$ is a subset of K that is a field using the same operations as those in K.

If F is a subfield of K, then K is called an ***extension field*** of F. Write K/F to indicate that K is an extension field of F.

For K an extension field of F, the ***degree of K over F*** is $[K\colon F]$ = the dimension of K as a vector space over F. (See §6.1.3.)

A ***field isomorphism*** is a function $\varphi\colon F_1 \to F_2$, where F_1 and F_2 are fields, such that φ is one-to-one, onto F_2, and satisfies the following for all $a, b \in F_1$:

- $\varphi(a+b) = \varphi(a) + \varphi(b)$;

- $\varphi(ab) = \varphi(a)\varphi(b)$.

A ***field automorphism*** is an isomorphism $\varphi\colon F \to F$, where F is a field. The set of all automorphisms of F is denoted $\mathrm{Aut}(F)$.

The ***characteristic*** of a field F is the smallest positive integer n such that $1 + \cdots + 1 = 0$, where there are n summands. If there is no such integer, F has characteristic 0 (also called characteristic ∞).

Facts:

1. Every field is a commutative ring with unity. A field satisfies all properties of a commutative ring with unity, and has the additional property that every nonzero element has a multiplicative inverse.

2. Every finite integral domain is a field.

3. A field is a commutative division ring.

4. If F is a field and a, $b \in F$ where $a \neq 0$, then $ax + b = 0$ has a unique solution in F.

5. If F is a field, every ideal in $F[x]$ is a principal ideal.

6. If p is a prime and n is any positive integer, then there is exactly one field (up to isomorphism) with p^n elements, the *Galois field* $GF(p^n)$. (§5.6.1)

7. If $\varphi\colon F \to F$ is a field automorphism, then

- $-\varphi(a) = \varphi(-a)$
- $\varphi(a^{-1}) = \varphi(a)^{-1}$

for all $a \neq 0$.

8. The intersection of all subfields of a field F is a field, called the *prime field* of F.

9. If F is a field, $\mathrm{Aut}(F)$ is a group under composition of functions.

10. The characteristic of a field is either 0 or prime.

11. Every field of characteristic 0 is isomorphic to a field that is an extension of $\mathcal{Q}$ and has $\mathcal{Q}$ as its prime field.

12. Every field of characteristic $p > 0$ is isomorphic to a field that is an extension of $\mathcal{Z}_p$ and has $\mathcal{Z}_p$ as its prime field.

13. If field F has characteristic $p > 0$, then $(a + b)^p = a^p + b^p$ for all $a, b \in F$.

14. If field F has characteristic $p > 0$, $f(x) \in \mathcal{Z}_p[x]$, and $\alpha \in F$ is a zero of $f(x)$, then $\alpha^p, \alpha^{p^2}, \alpha^{p^3}, \ldots$ are also zeros of $f(x)$.

15. If p is not a prime, then $\mathcal{Z}_p$ is not a field since $\mathcal{Z}_p - \{0\}$ will fail to be closed under multiplication. For example, $\mathcal{Z}_6$ is not a field since $2 \in \mathcal{Z}_6 - \{0\}$ and $3 \in \mathcal{Z}_6 - \{0\}$, but $2 \cdot 3 = 0 \notin \mathcal{Z}_6 - \{0\}$.

Examples:

1. The following table gives several examples of fields.

set and operations	$-a$	a^{-1}	*charac-teristic*	*order*
$\mathcal{Q}$, $\mathcal{R}$, $\mathcal{C}$, with usual addition and multiplication	$-a$	$1/a$	0	infinite
$\mathcal{Z}_p = \{0, 1, \ldots, p{-}1\}$ (p prime), addition and multiplication **mod** p	$p - a$ $(-0 = 0)$	$a^{-1} = b$, where ab **mod** $p = 1$	p	p
$F[x]/(f(x))$, $f(x)$ irreducible over field F, coset addition and multiplication (Example 2)	$-[a{+}(f(x))]=$ $-a{+}(f(x))$	$[a{+}(f(x))]^{-1}=$ $a^{-1}{+}(f(x))$	varies	varies
$GF(p^n){=}\mathcal{Z}_p[x]/(f(x))$, $f(x)$ of degree n irreducible over $\mathcal{Z}_p$ (p prime), addition and multiplication of cosets (*Galois field*)	$-[a{+}(f(x))]=$ $-a{+}(f(x))$	$[a{+}(f(x))]^{-1}=$ $a^{-1}{+}(f(x))$	p	p^n

2. *The field $F[x]/(f(x))$:* If F is any field and $f(x) \in F[x]$ of degree n is irreducible over F, the quotient ring structure $F[x]/(f(x))$ is a field. The elements of $F[x]/(f(x))$ are cosets of polynomials in $F[x]$ modulo $f(x)$, where $(f(x))$ is the principal ideal generated by $f(x)$. Polynomials $f_1(x)$ and $f_2(x)$ lie in the same coset if and only if $f(x)$ is a factor of $f_1(x) - f_2(x)$.

Using the division algorithm for polynomials, any polynomial $g(x) \in F[x]$ can be written as $g(x) = f(x)q(x) + r(x)$ where $q(x)$ and $r(x)$ are unique polynomials in $F[x]$ and $r(x)$ has degree $< n$. The equivalence class $g(x) + (f(x))$ can be identified with the polynomial $r(x)$, and thus $F[x]/(f(x))$ can be regarded as the field of all polynomials in $F[x]$ of degree $< n$.

5.6.2 EXTENSION FIELDS AND GALOIS THEORY

Throughout this subsection assume that field K is an extension of field F.

Definitions:

For $\alpha \in K$, $F(\alpha)$ is the smallest field containing α and F, called the ***field extension*** of F by α.

For $\alpha_1, \ldots, \alpha_n \in K$, $F(\alpha_1, \ldots, \alpha_n)$ is the smallest field containing $\alpha_1, \ldots, \alpha_n$ and F, called the ***field extension*** of F by $\alpha_1, \ldots, \alpha_n$.

If K is an extension field of F and $\alpha \in K$, then α is ***algebraic*** over F if α is a root of a nonzero polynomial in $F[x]$. If α is not the root of any nonzero polynomial in $F[x]$, then α is ***transcendental*** over F.

A complex number is an ***algebraic number*** if it is algebraic over $\mathcal{Q}$.

An ***algebraic integer*** is an algebraic number α that is a zero of a polynomial of the form $x^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0$ where each $a_i \in \mathcal{Z}$.

An extension field K of F is an ***algebraic extension*** of F if every element of K is algebraic over F. Otherwise K is a ***transcendental extension*** of F.

An extension field K of F is a ***finite extension*** of F if K is finite-dimensional as a vector space over F (see Fact 11). The dimension of K over F is written $[K\colon F]$.

Let α be algebraic over a field F. The ***minimal polynomial of α with respect to F*** is the monic irreducible polynomial $f(x) \in F[x]$ of smallest degree such that $f(\alpha) = 0$.

A polynomial $f(x) \in F[x]$ ***splits*** over K if $f(x) = \alpha(x - \alpha_1)\dots(x - \alpha_n)$ where α, α_1, $\dots, \alpha_n \in K$.

K is a ***splitting field*** (***root field***) of a nonconstant $f(x) \in F[x]$ if $f(x)$ splits over K and K is the smallest field with this property.

A polynomial $f(x) \in F[x]$ of degree n is ***separable*** if $f(x)$ has n distinct roots in its splitting field.

K is a ***separable extension*** of F if every element of K is the root of a separable polynomial in $F[x]$.

K is a ***normal extension*** of F if K/F is algebraic and every irreducible polynomial in $F[x]$ with a root in K has all its roots in K (i.e., splits in K).

K is a ***Galois extension*** of F if K is a normal, separable extension of F.

A field automorphism φ ***fixes set S elementwise*** if $\varphi(x) = x$ for all $x \in S$.

The ***fixed field*** of a subset $A \subseteq \mathrm{Aut}(F)$ is $F_A = \{x \in F \mid \varphi(x) = x \text{ for all } \varphi \in A\}$.

The ***Galois group*** of K over F is the group of automorphisms $G(K/F)$ of K that fix F elementwise. If K is a splitting field of $f(x) \in F[x]$, $G(K/F)$ is also known as the ***Galois group*** of $f(x)$. (Évariste Galois, 1811–1832)

Facts:

1. The elements of K that are algebraic over F form a subfield of K.

2. The algebraic numbers in $\mathcal{C}$ form a field; the algebraic integers form a subring of $\mathcal{C}$, called the *ring of algebraic integers*.

3. Every nonconstant polynomial has a unique splitting field, up to isomorphism.

4. If $f(x) \in F[x]$ splits as $\alpha(x - \alpha_1)\dots(x - \alpha_n)$, then the splitting field for $f(x)$ is $F(\alpha_1, \dots, \alpha_n)$.

5. If F is a field and $p(x) \in F[x]$ is a nonconstant polynomial, then there is an extension field K of F and $\alpha \in K$ such that $p(\alpha) = 0$.

6. If $f(x)$ is irreducible over F, then the ring $F[x]/(f(x))$ is an algebraic extension of F and contains a root of $f(x)$.

7. The field F is isomorphic to a subfield of any algebraic extension $F[x]/(f(x))$. The element $0 \in F$ corresponds to the coset of the zero polynomial; all other elements of F appear in $F[x]/(f(x))$ as cosets of the constant polynomials.

8. Every minimal polynomial is irreducible.

9. If K is a field extension of F and $\alpha \in K$ is a root of an irreducible polynomial $f(x) \in F[x]$ of degree $n \geq 1$, then $F(\alpha) = \{c_{n-1}\alpha^{n-1} + \dots + c_1\alpha + c_0 \mid c_i \in F \text{ for all } i\}$.

10. If K is an extension field of F and $\alpha \in K$ is algebraic over F, then

- there is a unique monic irreducible polynomial $f(x) \in F[x]$ of smallest degree (the *minimum polynomial*) such that $f(\alpha) = 0$;
- $F(\alpha) \cong F[x]/(f(x))$;

- if the degree of α over F is n, then $K = \{a_0 + a_1\alpha + a_2\alpha^2 + \cdots + a_{n-1}\alpha^{n-1} \mid a_0, a_1, \ldots, a_{n-1} \in F\}$; in fact, K is an n-dimensional vector space over F, with basis $1, \alpha, \alpha^2, \ldots, \alpha^{n-1}$.

11. If K is an extension field of F and $x \in K$ is transcendental over F, then $F(\alpha) \cong$ the field of all fractions $f(x)/g(x)$ where $f(x)$, $g(x) \in F[x]$ and $g(x)$ is not the zero polynomial.

12. K is a splitting field of some polynomial $f(x) \in F[x]$ if and only if K is a Galois extension of F.

13. If K is a splitting field for separable $f(x) \in F[x]$ of degree n, then $G(K, F)$ is isomorphic to a subgroup of the symmetric group S_n.

14. If K is a splitting field of $f(x) \in F[x]$, then

- every element of $G(K/F)$ permutes the roots of $f(x)$ and is completely determined by its effect on the roots of $f(x)$;
- $G(K/F)$ is isomorphic to a group of permutations of the roots of $f(x)$.

15. If K is a splitting field for separable $f(x) \in F[x]$, then $|G(K/F)| = [K\colon F]$.

16. For $[K\colon F]$ finite, K is a normal extension of F if and only if K is a splitting field of some polynomial in $F[x]$.

17. *The fundamental theorem of Galois theory*: If K is a normal extension of F, where F is either finite or has characteristic 0, then there is a one-to-one correspondence Φ between the lattice of all fields K', where $F \subseteq K' \subseteq K$, and the lattice of all subgroups H of the Galois group $G(K/F)$:

$$\Phi(K') = G(K/K') \quad \text{and} \quad \Phi^{-1}(H) = K_H.$$

The correspondence Φ has the following properties:

- for fields K' and K'' where $F \subseteq K' \subseteq K$ and $F \subseteq K'' \subseteq K$

  $$K' \subseteq K'' \longleftrightarrow \Phi(K'') \subseteq \Phi(K').$$

  That is, $G(K/K'') \subseteq G(K/K')$.
- Φ interchanges the operations meet and join for the lattice of subfields and the lattice of subgroups:

  $$\Phi(K' \wedge K'') = G(K/K') \vee G(K/K''),$$
  $$\Phi(K' \vee K'') = G(K/K') \wedge G(K/K'').$$

  (Note: In the lattice of fields [groups], $A \wedge B = A \cap B$ and $A \vee B$ is the smallest field [group] containing A and B.)
- K' is a normal extension of F if and only if $G(K/K')$ is a normal subgroup of $G(K/F)$.

18. *Formulas for solving polynomial equations of degrees* 2, 3, *or* 4:

- *second-degree (quadratic) equation* $ax^2 + bx + c = 0$: the quadratic formula gives the solutions $\dfrac{-b \pm \sqrt{b^2 - 4ac}}{2a}$;
- *third-degree (cubic) equation* $a_3x^3 + a_2x^2 + a_1x + a_0 = 0$:

  (1) divide by a_3 to obtain $x^3 + b_2x^2 + b_1x + b_0 = 0$,

(2) make the substitution $x = y - \frac{b_2}{3}$ to obtain an equation of the form $y^3 + cy + d = 0$, with solutions $y = \sqrt[3]{\frac{-d}{2} + \sqrt{\frac{d^2}{4} + \frac{c^3}{27}}} + \sqrt[3]{\frac{-d}{2} - \sqrt{\frac{d^2}{4} + \frac{c^3}{27}}}$,

(3) use the substitution $x = y - \frac{b_2}{3}$ to obtain the solutions to the original equation;

- *fourth-degree (quartic) equation* $a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 = 0$:

  (1) divide by a_4 to obtain $x^4 + ax^3 + bx^2 + cx + d = 0$,

  (2) solve the *resolvent* equation $y^3 - by^s + (ac - 4d)y + (-a^2d + 4bd - c^2) = 0$ to obtain a root z,

  (3) solve the pair of quadratic equations:

$$x^2 + \tfrac{a}{2}x + \tfrac{z}{2} = \pm\sqrt{\left(\tfrac{a^2}{4} - b + z\right)x^2 + \left(\tfrac{a}{2}z - c\right)x + \left(\tfrac{z^2}{4} - d\right)}$$

to obtain the solutions to the original equation.

19. A general method for solving cubic equations algebraically was given by Nicolo Fontana (1500–1557), also called Tartaglia. The method is often referred to as Cardano's method because Girolamo Cardano (1501–1576) published the method. Ludovico Ferrari (1522–1565), a student of Cardano, discovered a general method for solving quartic equations algebraically.

20. *Equations of degree 5 or more*: In 1824 Abel proved that the general quintic polynomial equation $a_5x^5+\cdots+a_1x+a_0 = 0$ (and those of higher degree) are not solvable by radicals; that is, there can be no formula for writing the roots of such equations using only the basic arithmetic operations and the taking of nth roots. Évariste Galois (1811–1832) demonstrated the existence of such equations that are not solvable by radicals and related solvability by radicals of polynomial equations to determining whether the associated permutation group (the Galois group) of roots is solvable. (See Application 1.)

Examples:

1. *$\mathcal{C}$ as an algebraic extension of $\mathcal{R}$*: Let $f(x) = x^2 + 1 \in \mathcal{R}[x]$ and $\alpha = x + (x^2 + 1) \in \mathcal{R}[x]/(x^2 + 1)$. Then $\alpha^2 = -1$. Thus, α behaves like i (since $i^2 = -1$). Hence $\mathcal{R}[x]/(x^2 + 1) = \{c_1\alpha + c_0 \mid c_1, c_0 \in \mathcal{R}\} \cong \{c_1i + c_0 \mid c_0, c_1 \in \mathcal{R}\} = \mathcal{C}$.

2. *Algebraic extensions of $\mathcal{Z}_p$*: If $f(x) \in \mathcal{Z}_p$ is an irreducible polynomial of degree n, then the algebraic extension $\mathcal{Z}_p[x]/(f(x))$ is a *Galois field*.

3. If $f(x) = x^4 - 2x^2 - 3 \in \mathcal{Q}[x]$, its splitting field is

$$\mathcal{Q}(\sqrt{3}, i) = \{a + b\sqrt{3} + ci + di\sqrt{3} \mid a, b, c, d \in \mathcal{Q}\}.$$

There are three intermediate fields: $\mathcal{Q}(\sqrt{3})$, $\mathcal{Q}(i)$, and $\mathcal{Q}(i\sqrt{3})$, as illustrated below. The Galois group $G(\mathcal{Q}(\sqrt{3}, i)/\mathcal{Q}) = \{e, \phi_1, \phi_2, \phi_3\}$ where

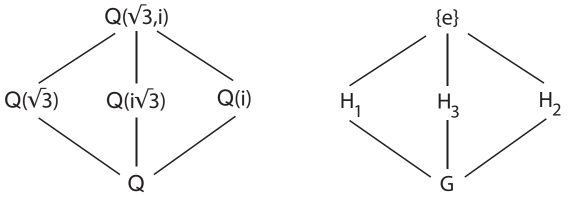
$$\begin{aligned}
\phi_1(a + b\sqrt{3} + ci + di\sqrt{3}) &= a + b\sqrt{3} - ci - di\sqrt{3},\\
\phi_2(a + b\sqrt{3} + ci + di\sqrt{3}) &= a - b\sqrt{3} + ci - di\sqrt{3},\\
\phi_3(a + b\sqrt{3} + ci + di\sqrt{3}) &= a - b\sqrt{3} - ci + di\sqrt{3} = \phi_2\phi_1 = \phi_1\phi_2,\\
e(a + b\sqrt{3} + ci + di\sqrt{3}) &= a + b\sqrt{3} + ci + di\sqrt{3}.
\end{aligned}$$

$G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q})$ has the following subgroups:

$$\begin{aligned}
G &= G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q}) = \{e,\phi_1,\phi_2,\phi_3\},\\
H_1 &= G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q}(\sqrt{3})) = \{e,\phi_1\},\\
H_2 &= G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q}(i)) = \{e,\phi_2\},\\
H_3 &= G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q}(i\sqrt{3})) = \{e,\phi_3\},\\
\{e\} &= G(\mathcal{Q}(\sqrt{3},i),\mathcal{Q}(\sqrt{3},i)).
\end{aligned}$$

The correspondence between fields and Galois groups is shown in the following table and figure.

field	*Galois group*
$\mathcal{Q}(\sqrt{3},i)$	$\{e\}$
$\mathcal{Q}(\sqrt{3})$	H_1
$\mathcal{Q}(i\sqrt{3})$	H_3
$\mathcal{Q}(i)$	H_2
$\mathcal{Q}$	G



4. *Cyclotomic extensions*: The nth roots of unity are the solutions to $x^n - 1 = 0$: $1, \omega, \omega^2, \ldots, \omega^{n-1}$, where $\omega = e^{2\pi i/n}$. The extension field $\mathcal{Q}(\omega)$ is a *cyclotomic extension* of $\mathcal{Q}$. If $p > 2$ is prime, then $G(\mathcal{Q}(\omega),\mathcal{Q})$ is a cyclic group of order $p-1$ and is isomorphic to $\mathcal{Z}_p^*$ (the multiplicative group of nonzero elements of $\mathcal{Z}_p$).

Applications:

1. *Solvability by radicals*: A polynomial equation $f(x) = 0$ is *solvable by radicals* if each root can be expressed in terms of the coefficients of the polynomial, using only the operations of addition, subtraction, multiplication, division, and the taking of nth roots.

If F is a field of characteristic 0 and $f(x) \in F[x]$ has K as splitting field, then $f(x) = 0$ is solvable by radicals if and only if $G(K,F)$ is a solvable group. Since there are polynomials whose Galois groups are not solvable, there are polynomials whose roots cannot be found by elementary algebraic methods. For example, the polynomial $x^5 - 36x + 2$ has the symmetric group S_5 as its Galois group, which is not solvable. Hence, the roots of $x^5 - 36x + 2 = 0$ cannot be found by elementary algebraic methods. This example shows that there can be no algebraic formula for solving all fifth-degree equations.

2. *Straightedge and compass constructibility*: Using only a straightedge (unmarked ruler) and a compass, there is no general method for

- trisecting angles (given an angle whose measure is α, to construct an angle with measure $\frac{\alpha}{3}$);
- duplicating the cube (given the side of a cube C_1, to construct the side of a cube C_2 that has double the volume of C_1);

- squaring the circle (given a circle of area A, to construct a square with area A);
- constructing a regular n-gon for all $n \geq 3$.

Straightedge and compass constructions yield only lengths that can be obtained by addition, subtraction, multiplication, division, and taking square roots. Beginning with lengths that are rational numbers, each of these operations yields field extensions $\mathcal{Q}(a)$ and $\mathcal{Q}(b)$ where a and b are coordinates of a point constructed from points in $\mathcal{Q} \times \mathcal{Q}$. These operations force $[\mathcal{Q}(a)\colon \mathcal{Q}]$ and $[\mathcal{Q}(b)\colon \mathcal{Q}]$ to be powers of 2. However, trisecting angles, duplicating cubes, and squaring circles all yield extensions of $\mathcal{Q}$ such that the degrees of the extensions are not powers of 2. Hence these three types of constructions are not possible with straightedge and compass.

5.6.3 FINITE FIELDS

Finite fields have a wide range of applications in various areas of computer science and engineering: coding theory, combinatorics, computer algebra, cryptology, generation of pseudorandom numbers, switching circuit theory, and symbolic computation.

Throughout this subsection assume that F is a finite field.

Definitions:

A ***finite field*** is a field with a finite number of elements.

The ***Galois field*** $GF(p^n)$ is the algebraic extension $\mathcal{Z}_p[x]/(f(x))$ of the finite field $\mathcal{Z}_p$ where p is a prime and $f(x)$ is an irreducible polynomial over $\mathcal{Z}_p$ of degree n. (See Fact 1.)

A ***primitive element*** of $GF(p^n)$ is a generator of the cyclic group of nonzero elements of $GF(p^n)$ under multiplication.

Let α be a primitive element of $GF(p^n)$. The ***discrete exponential function*** (with base α) is the function $\exp_\alpha\colon \{0,1,2,\ldots,p^n-2\} \to GF(p^n)^*$ defined by the rule $\exp_\alpha k = \alpha^k$.

Let α be a primitive element of $GF(p^n)$. The ***discrete logarithm*** or ***index function*** (with base α) is the function $\mathrm{ind}_\alpha\colon GF(p^n)^* \to \{0,1,2,\ldots,p^n-2\}$ where $\mathrm{ind}_\alpha(x) = k$ if and only if $x = \alpha^k$.

Let α be a primitive element of $GF(p^n)$. The ***Zech logarithm*** (***Jacobi logarithm***) is the function $Z\colon \{1,\ldots,p^n-1\} \to \{0,\ldots,p^n-2\}$ such that $\alpha^{Z(k)} = 1+\alpha^k$; if $1+\alpha^k = 0$, then $Z(k) = 0$.

Facts:

1. *Existence of finite fields*: For each prime p and positive integer n there is exactly one field (up to isomorphism) with p^n elements—the field $GF(p^n)$, also written F_{p^n}.

2. *Construction of finite fields*: Given an irreducible polynomial $f(x) \in \mathcal{Z}_p[x]$ of degree n and a zero α of $f(x)$,

$$GF(p^n) \cong \mathcal{Z}_p[x]/(f(x)) \cong \{c_{n-1}\alpha^{n-1} + \cdots + c_1\alpha + c_0 \mid c_i \in \mathcal{Z}_p \text{ for all } i\}.$$

3. If F is a finite field, then

- F has p^n elements for some prime p and positive integer n;
- F has characteristic p for some prime p;

- F is an extension of $\mathcal{Z}_p$.

4. $[GF(p^n)\colon \mathcal{Z}_p] = n$.

5. $GF(p^n) =$ the field of the p^n roots of $x^{p^n} - x \in \mathcal{Z}_p[x]$.

6. The minimal polynomial of $\alpha \in GF(p^n)$ with respect to Z_p is

$$f(x) = (x-\alpha)(x-\alpha^p)(x-\alpha^{p^2})\dots(x-\alpha^{p^i})$$

where i is the smallest positive integer such that $\alpha^{p^{i+1}} = \alpha$.

7. If a field F has order p^n, then every subfield of F has order p^k for some k that divides n.

8. The multiplicative group of nonzero elements of a finite field F is a cyclic group.

9. If a field F has m elements, then the multiplicative order of each nonzero element of F is a divisor of $m-1$.

10. If a field F has m elements and d is a divisor of $m-1$, then there is an element of F of order d.

11. Each discrete logarithm function has the following properties:

$$\begin{aligned}&\text{ind}_\alpha(xy) \equiv \text{ind}_\alpha x + \text{ind}_\alpha y \pmod{p^n - 1};\\&\text{ind}_\alpha(xy^{-1}) \equiv \text{ind}_\alpha x - \text{ind}_\alpha y \pmod{p^n - 1};\\&\text{ind}_\alpha(x^k) \equiv k\ \text{ind}_\alpha x \pmod{p^n - 1}.\end{aligned}$$

12. The discrete logarithm function ind_α is the inverse of the discrete exponential function $\exp_\alpha$. That is, $\text{ind}_\alpha x = y$ if and only if $\exp_\alpha y = x$.

13. A discrete logarithm function can be used to facilitate multiplication and division of elements of $GF(p^n)$.

14. The Zech logarithm facilitates the addition of elements α^i and α^j $(i > j)$ in $GF(p^n)$, since $\alpha^i + \alpha^j = \alpha^j(\alpha^{i-j} + 1) = \alpha^j \cdot \alpha^{Z(i-j)} = \alpha^{j+Z(i-j)}$. (Note that the values of the Zech logarithm function depend on the primitive element used.)

15. There are $\frac{1}{k}\prod_{d|k}\mu(\frac{k}{d})p^{nd}$ irreducible polynomials of degree k over $GF(p^n)$, where μ is the Möbius function (§2.7).

Examples:

1. If p is prime, $\mathcal{Z}_p$ is a finite field and $\mathcal{Z}_p \cong GF(p)$.

2. The field $\mathcal{Z}_2 = F_2$:

+	0	1
0	0	1
1	1	0

·	0	1
0	0	0
1	0	1

3. The field $\mathcal{Z}_3 = F_3$:

+	0	1	2
0	0	1	2
1	1	2	0
2	2	0	1

·	0	1	2
0	0	0	0
1	0	1	2
2	0	2	1

4. *Construction of* $GF(2^2) = F_4$:

$$GF(2^2) = \mathcal{Z}_2[x]/(x^2+x+1) = \{c_1\alpha + c_0 \mid c_1, c_0 \in \mathcal{Z}_2\} = \{0, 1, \alpha, \alpha+1\}$$

where α is a zero of x^2+x+1; i.e., $\alpha^2+\alpha+1=0$. The nonzero elements of $GF(p^n)$ can also be written as powers of α as α, $\alpha^2=-\alpha-1=\alpha+1$, $\alpha^3=\alpha\cdot\alpha^2=\alpha(\alpha+1)=\alpha^2+\alpha=(\alpha+1)+\alpha=2\alpha+1=1$.

Thus, $GF(2^2)=\{0,1,\alpha,\alpha^2\}$ has the following addition and multiplication tables:

$+$	0	1	α	α^2
0	0	1	α	α^2
1	1	0	α^2	α
α	α	α^2	0	1
α^2	α^2	α	1	0

$\cdot$	0	1	α	α^2
0	0	0	0	0
1	0	1	α	α^2
α	0	α	α^2	1
α^2	0	α^2	1	α

5. *Construction of* $GF(2^3)=F_8$: Let $f(x)=x^3+x+1\in\mathcal{Z}_2[x]$ and let α be a root of $f(x)$. Then $GF(2^3)=\{c_2\alpha^2+c_1\alpha+c_0 \mid c_0,c_1,c_2\in\mathcal{Z}_2\}$ where $\alpha^3+\alpha+1=0$.

The elements of $GF(2^3)$ (using α as generator) are

$$\begin{array}{llll} 0, & \alpha, & \alpha^2, & \alpha^3=\alpha+1 \\ \alpha^4=\alpha^2+\alpha, & \alpha^5=\alpha^2+\alpha+1, & \alpha^6=\alpha^2+1, & 1\ (=\alpha^7). \end{array}$$

Multiplication is carried out using the ordinary rules of exponents and the fact that $\alpha^7=1$. The following Zech logarithm values can be used to construct the table for addition: $Z(1)=3$, $Z(2)=6$, $Z(3)=1$, $Z(4)=5$, $Z(5)=4$, $Z(6)=2$, $Z(7)=0$. For example $\alpha^3+\alpha^5=\alpha^3\cdot\alpha^{Z(5-3)}=\alpha^3\cdot\alpha^6=\alpha^9=\alpha^2$.

Using strings of 0s and 1s to represent the elements, $0=000$, $1=001$, $\alpha=010$, $\alpha+1=011$, $\alpha^2=100$, $\alpha^2+\alpha=110$, $\alpha^2+1=101$, $\alpha^2+\alpha+1=111$, yields the following tables for addition and multiplication:

$+$	000	001	010	011	100	101	110	111
000	000	001	010	011	100	101	110	111
001	001	000	011	010	101	100	111	110
010	010	011	000	001	110	111	100	101
011	011	010	001	000	111	110	101	100
100	100	101	110	111	000	001	010	011
101	101	100	111	110	001	000	011	010
110	110	111	100	101	010	011	000	001
111	111	110	101	100	011	010	001	000

$\cdot$	000	001	010	011	100	101	110	111
000	000	000	000	000	000	000	000	000
001	000	001	010	011	100	101	110	111
010	000	010	100	110	011	001	111	101
011	000	011	110	101	111	100	001	010
100	000	100	011	111	110	010	101	001
101	000	101	001	100	010	111	011	110
110	000	110	111	001	101	011	010	100
111	000	111	101	010	001	110	100	011

The same field can be constructed using $g(x)=x^3+x^2+1$ instead of $f(x)=x^3+x+1$ and β as a root of $g(x)$ ($\beta^3+\beta^2+1=0$). The elements (using β as generator) are 0, β, β^2, $\beta^3=\beta^2+1$, $\beta^4=\beta^2+\beta+1$, $\beta^5=\beta+1$, $\beta^6=\beta^2+\beta$, $1\ (=\beta^7)$.

The polynomial $g(x)$ yields the following Zech logarithm values, which can be used to construct the table for addition: $Z(1) = 5$, $Z(2) = 3$, $Z(3) = 2$, $Z(4) = 6$, $Z(5) = 1$, $Z(6) = 4$, $Z(7) = 0$. This field is isomorphic to the field defined using $f(x) = x^3 + x + 1$.

6. The following table lists the irreducible polynomials of degree at most 8 in $\mathcal{Z}_2[x]$. Each polynomial is represented by the string of its coefficients, beginning with the highest power. For example, $x^3 + x + 1$ is represented by 1011. For more extensive tables of irreducible polynomials over certain finite fields, see [LiNi94].

degree 1:	10	11				
degree 2:	111					
degree 3:	1011	1101				
degree 4:	10011	11001	11111

5.7 LATTICES

5.7.1 BASIC CONCEPTS

Definitions:

A ***lattice*** $(L, \vee, \wedge)$ is a nonempty set L closed under two binary operations $\vee$ (*join*) and $\wedge$ (*meet*) such that the following laws are satisfied for all $a, b, c \in L$:

- *associative laws*: $a \vee (b \vee c) = (a \vee b) \vee c$ and $a \wedge (b \wedge c) = (a \wedge b) \wedge c$;
- *commutative laws*: $a \vee b = b \vee a$ and $a \wedge b = b \wedge a$;
- *absorption laws*: $a \vee (a \wedge b) = a$ and $a \wedge (a \vee b) = a$.

Lattices L_1 and L_2 are ***isomorphic*** (as lattices) if there is a function $\varphi \colon L_1 \to L_2$ that is one-to-one, onto L_2 and preserves $\vee$ and $\wedge$: $\varphi(a \vee b) = \varphi(a) \vee \varphi(b)$ and $\varphi(a \wedge b) = \varphi(a) \wedge \varphi(b)$ for all $a, b \in L_1$.

L_1 is a ***sublattice*** of lattice L if $L_1 \subseteq L$ and L_1 is a lattice using the same operations as those used in L.

The ***dual*** of a statement in a lattice is the statement obtained by interchanging the operations $\vee$ and $\wedge$, and interchanging the elements 0 (lower bound) and 1 (upper bound). (See §5.7.2.)

An ***order relation*** $\leq$ can be defined on a lattice so that $a \leq b$ means that $a \vee b = b$, or, equivalently, that $a \wedge b = a$. Write $a < b$ if $a \leq b$ and $a \neq b$.

Facts:

1. If L is a lattice and $a, b \in L$, then $a \wedge b$ and $a \vee b$ are unique.

2. *Lattices as partially ordered sets*: Every lattice is a partially ordered set using the order relation $\leq$. (See §1.4.3; also see Chapter 11 for extended coverage.)

3. Every partially ordered set L in which $\mathrm{glb}\,\{a, b\}$ and $\mathrm{lub}\,\{a, b\}$ exist for all $a, b \in L$ can be regarded as a lattice by defining $a \vee b = \mathrm{lub}\,\{a, b\}$ and $a \wedge b = \mathrm{glb}\,\{a, b\}$.

4. *The duality principle holds in all lattices*: If a theorem is the consequence of the definition of lattice, then the dual of the statement is also a theorem.

5. *Lattice diagrams*: Every finite lattice can be pictured in a poset diagram (Hasse diagram), called a *lattice diagram*.

6. *Idempotent laws*: $a \vee a = a$ and $a \wedge a = a$ for all $a \in L$.

Example:

1. The following table gives examples of lattices.

set	$\vee$ *(join)*	$\wedge$ *(meet)*
$\mathcal{N}$	$a \vee b = \mathrm{lcm}\{a, b\}$	$a \wedge b = \gcd\{a, b\}$
$\mathcal{N}$	$a \vee b = \max\{a, b\}$	$a \wedge b = \min\{a, b\}$
$\mathcal{Z}_2^n$	$(a_1, \ldots, a_n) \vee (b_1, \ldots, b_n) =$ $(\max(a_1, b_1), \ldots, \max(a_n, b_n))$	$(a_1, \ldots, a_n) \vee (b_1, \ldots, b_n) =$ $(\min(a_1, b_1), \ldots, \min(a_n, b_n))$
all subgroups of a group G	$H_1 \vee H_2 =$ the intersection of all subgroups of G containing H_1 and H_2	$H_1 \wedge H_2 = H_1 \cap H_2$
all subsets of set S	$A_1 \vee A_2 = A_1 \cup A_2$	$A_1 \wedge A_2 = A_1 \cap A_2$

5.7.2 SPECIALIZED LATTICES

Definitions:

A lattice L is ***distributive*** if the following are true for all $a, b, c \in L$:

- $a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$;
- $a \vee (b \wedge c) = (a \vee b) \wedge (a \vee c)$.

A ***lower bound*** (***smallest element***, ***least element***) in a lattice L is an element $0 \in L$ such that $0 \wedge a = 0$ (equivalently, $0 \leq a$) for all $a \in L$.

An ***upper bound*** (***largest element***, ***greatest element***) in a lattice L is an element $1 \in L$ such that $1 \vee a = 1$ (equivalently, $a \leq 1$) for all $a \in L$.

A lattice L is ***bounded*** if L contains a lower bound 0 and an upper bound 1.

A lattice L is ***complemented*** if

- L is bounded;
- for each $a \in L$ there is an element $b \in L$ (called a ***complement*** of a) such that $a \vee b = 1$ and $a \wedge b = 0$.

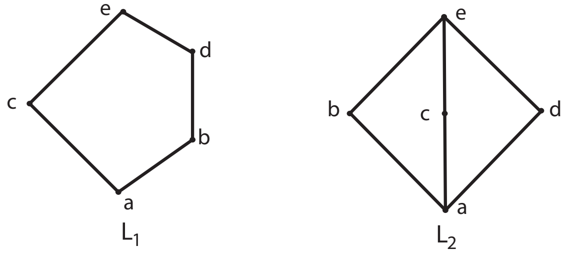
An element a in a bounded lattice L is an ***atom*** if $0 < a$ and there is no element $b \in L$ such that $0 < b < a$.

Facts:

1. Each of the distributive properties in a lattice implies the other.

2. Not every lattice is distributive. (See Example 1.)

3. If a lattice is not distributive, it must contain a sublattice isomorphic to one of the two lattices in the following figure.



4. Every finite lattice is bounded: if $L = \{a_1, \ldots, a_n\}$, then

$$1 = a_1 \vee \cdots \vee a_n \qquad \text{and} \qquad 0 = a_1 \wedge \cdots \wedge a_n.$$

5. Some infinite lattices are bounded, while others are not. (See Examples 2 and 3.)

6. In a complemented lattice, complements are not necessarily unique. See the lattice in Example 4.

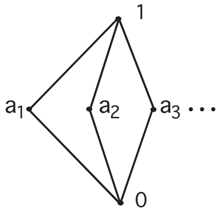
7. If L is a finite, complemented, distributive lattice and $a \in L$, then there is exactly one set of atoms $\{a_1, \ldots, a_k\}$ such that $a = a_1 \vee \cdots \vee a_k$.

Examples:

1. Neither lattice in Fact 3 is distributive. For example, in lattice L_1, $d \vee (b \wedge c) = d$, but $(d \vee b) \wedge (d \vee c) = b$. And in L_2, $d \vee (b \wedge c) = d$, but $(d \vee b) \wedge (d \vee c) = a$.

2. The lattice $(\mathcal{N}, \vee, \wedge)$ where $a \vee b = \max(a, b)$ and $a \wedge b = \min(a, b)$ is not bounded; there is a lower bound (the integer 0), but there is no upper bound.

3. The following infinite lattice is bounded. The element 1 is an upper bound and the element 0 is a lower bound.



4. The lattice in Example 3 is complemented, but complements are not unique in that lattice. For example, the element a_1 has $a_2, a_3, \ldots$ as complements.

5. In lattice L_1 of Fact 3, b and c are atoms. In the lattice of all subsets of a set S (see Example 1), the atoms are the subsets of S of size 1.

5.8 BOOLEAN ALGEBRAS

Boolean algebra is a generalization of the algebra of sets and the algebra of logical propositions. It forms an abstract model of the design of circuits.

5.8.1 BASIC CONCEPTS

Definitions:

A ***Boolean algebra*** $(B, +, \cdot, ', 0, 1)$ consists of a set B closed under two binary operations, $+$ (*addition*) and $\cdot$ (*multiplication*), and one monadic operation, $'$ (*complementation*), and having two distinct elements, 0 and 1, such that the following laws are true for all $a, b, c \in B$:

- *commutative laws:* $a + b = b + a$ and $a \cdot b = b \cdot a$;
- *distributive laws:* $a \cdot (b + c) = (a \cdot b) + (a \cdot c)$ and $a + (b \cdot c) = (a + b) \cdot (a + c)$;
- *identity laws:* $a + 0 = a$ and $a \cdot 1 = a$;
- *complement laws:* $a + a' = 1$ and $a \cdot a' = 0$.

(George Boole, 1813–1864)

Notation: It is common practice to omit the "$\cdot$" symbol in a Boolean algebra, writing ab instead of $a \cdot b$. The complement operation is also written using an overline: $x' = \overline{x}$. By convention, complementation is done first, then multiplication, and finally addition. For example, $a + bc'$ means $a + (b(c'))$.

The ***dual*** of a statement in a Boolean algebra is the statement obtained by interchanging the operations $+$ and $\cdot$, and interchanging the elements 0 and 1 in the original statement.

Boolean algebras B_1 and B_2 are ***isomorphic*** (as Boolean algebras) if there is a function $\varphi\colon B_1 \to B_2$ that is one-to-one and onto B_2 such that for all $a, b \in B_1$

- $\varphi(a + b) = \varphi(a) + \varphi(b)$;
- $\varphi(ab) = \varphi(a)\varphi(b)$;
- $\varphi(a') = \varphi(a)'$.

An element $a \neq 0$ in a Boolean algebra is an ***atom*** if the following holds: if $xa = x$, then either $x = 0$ or $x = a$; that is, if $x \leq a$, then either $x = 0$ or $x = a$ (see Fact 1).

The binary operation NAND, written $\,|\,$, is defined by $a \,|\, b = (ab)'$.

The binary operation NOR, written $\downarrow$, is defined by $a \downarrow b = (a + b)'$.

The binary operation XOR, written $\oplus$, is defined by $a \oplus b = ab' + a'b$.

Facts:

1. Every Boolean algebra is a bounded, distributive, complemented lattice where $a \vee b = a+b$ and $a \wedge b = ab$. Hence, every Boolean algebra is a partially ordered set (where $a \leq b$ if and only if $a+b=b$, or, equivalently, $ab=a$ or $a'+b=1$ or $ab'=0$).

2. The *duality principle* holds in all Boolean algebras: if a theorem is the consequence of the definition of Boolean algebra, then the dual of the theorem is also a theorem.

3. *Structure of Boolean algebras*: Every finite Boolean algebra is isomorphic to $\{0,1\}^n$ for some positive integer n. Hence every finite Boolean algebra has 2^n elements. The atoms are the n n-tuples of 0s and 1s with a 1 in exactly one position.

4. If B is a finite Boolean algebra and $b \in B$ ($b \neq 0$), there is exactly one set of atoms $a_1, \ldots, a_k$ such that $b = a_1 + \cdots + a_k$.

5. If a Boolean algebra B has n atoms, then B has 2^n elements.

6. The following laws hold in the Boolean algebra B, for all $a,b,c \in B$:

- *associative laws:* $a+(b+c)=(a+b)+c$ and $a(bc)=(ab)c$;
  (Hence there is no ambiguity in writing $a+b+c$ and abc.)
- *idempotent laws:* $a+a=a$, $aa=a$;
- *absorption laws:* $a(a+b)=a$, $a+ab=a$;
- *domination (boundedness) laws:* $a+1=1$ and $a0=0$;
- *double complement (involution) law:* $(a')'=a$;
- *De Morgan's laws:* $(a+b)'=a'b'$ and $(ab)'=a'+b'$;
- *uniqueness of complement:* if $a+b=1$ and $ab=0$, then $b=a'$.

7. Since every Boolean algebra is a lattice, every finite Boolean algebra can be pictured using a partially ordered set diagram. (§11.1)

Examples:

1. $\{0,1\}$ is a Boolean algebra, where addition, multiplication, and complementation are defined in the following tables:

$+$	0	1
0	0	1
1	1	1

$\cdot$	0	1
0	0	0
1	0	1

x	x'
0	1
1	0

2. If S is any set, then $\mathcal{P}(S)$ (the set of all subsets of S) is a Boolean algebra where

$$A_1 + A_2 = A_1 \cup A_2, \quad A_1 \cdot A_2 = A_1 \cap A_2, \quad A' = \overline{A}$$

and $0 = \emptyset$ and $1 = S$.

3. Given n variables, the set of all compound propositions in these variables (identified with their truth tables) is a Boolean algebra where

$$p+q = p \vee q \quad p \cdot q = p \wedge q \quad \overline{p} = \neg p$$

and 0 is a contradiction (the truth table with only values F) and 1 is a tautology (the truth table with only values T).

4. If B is any Boolean algebra, then $B^n = \{(a_1, \ldots, a_n) \mid a_i \in B \text{ for all } i\}$ is a Boolean algebra, where the operations are performed coordinatewise:

$$(a_1,\ldots,a_n)+(b_1,\ldots,b_n)=(a_1+b_1,\ldots,a_n+b_n);$$
$$(a_1,\ldots,a_n)\cdot(b_1,\ldots,b_n)=(a_1\cdot b_1,\ldots,a_n\cdot b_n);$$
$$(a_1,\ldots,a_n)'=(a_1',\ldots,a_n').$$

In this Boolean algebra $0=(0,\ldots,0)$ and $1=(1,\ldots,1)$.

5. The statements in each of the following pairs are duals of each other:

$$a+b=cd,\quad ab=c+d;$$
$$a+(b+c)=(a+b)+c,\quad a(bc)=(ab)c;$$
$$a+1=1,\ a0=0.$$

5.8.2 BOOLEAN FUNCTIONS

Definitions:

A ***Boolean expression*** in the variables $x_1,\ldots,x_n$ is an expression defined recursively by

- 0, 1, and all variables x_i are Boolean expressions in $x_1,\ldots,x_n$;
- if E and F are Boolean expressions in the variables $x_1,\ldots,x_n$, then (EF), $(E{+}F)$, and E' are Boolean expressions in the variables $x_1,\ldots,x_n$.

A ***Boolean function*** of degree n is a function $f\colon\{0,1\}^n\to\{0,1\}$.

A ***literal*** is a Boolean variable or its complement.

A ***minterm*** of the Boolean variables $x_1,\ldots,x_n$ is a product of the form $y_1\ldots y_n$ where for each i, y_i is equal to x_i or x_i'.

A ***maxterm*** of the Boolean variables $x_1,\ldots,x_n$ is a sum of the form $y_1+\cdots+y_n$ where for each i, y_i is equal to x_i or x_i'.

A Boolean function of degree n is in ***disjunctive normal form*** (***DNF***) (or ***sum-of-products expansion***) if it is written as a sum of distinct minterms in the variables $x_1,\ldots,x_n$. (*Note*: disjunctive normal form is sometimes called *full* disjunctive normal form.)

A Boolean function is in ***conjunctive normal form*** (***CNF***) (or ***product-of-sums expansion***) if it is written as a product of distinct maxterms.

A set of operators in a Boolean algebra is ***functionally complete*** if every Boolean function can be written using only these operators.

Facts:

1. Every Boolean function can be written as a Boolean expression.

2. There are 2^{2^n} Boolean functions of degree n. Examples of the 16 different Boolean functions with two variables, x and y, are given in the following table.

x	y	1	$x+y$	$x+y'$	$x'+y$	$x\vert y$	x	y	$x\oplus y$	$(x\oplus y)'$	y'	x'	xy	xy'	$x'y$	$x\downarrow y$	0
1	1	1	1	1	1	0	1	1	0	1	0	0	1	0	0	0	0
1	0	1	1	1	0	1	1	0	1	0	1	0	0	1	0	0	0
0	1	1	1	0	1	1	0	1	1	0	0	1	0	0	1	0	0
0	0	1	0	1	1	1	0	0	0	1	1	1	0	0	0	1	0

3. Every Boolean function (not identically 0) can be written in disjunctive normal form. Either of the following two methods can be used:

(a) Rewrite the expression for the function so that no parentheses remain. For each term that does not have a literal for a variable x_i, multiply that term by $x_i + x_i'$. Multiply out so that no parentheses remain. Use the idempotent law to remove any duplicate terms or duplicate factors.

(b) Make a table of values for the function. For each row where the function has the value 1, form a minterm that yields 1 in only that row. Form the sum of these minterms.

4. Every Boolean function (not identically 1) can be written in conjunctive normal form. Any of the following three methods can be used:

(a) Write the negation of the expression in disjunctive normal form. Use De Morgan's laws to take the negation of this expression.

(b) Make a table of values for the function. For each row where the function has the value 0, form a minterm that yields 1 in only that row. Form the sum of these minterms. Use De Morgan's laws to take the complement of this sum.

(c) Make a table of values for the function. For each row where the function has the value 0, form a maxterm that yields 0 in only that row. Form the product of these maxterms.

5. The following are examples of functionally complete sets, with explanations showing how any Boolean function can be written using only these operators:

- $\{+\,,\,\cdot\,,\,'\}$ disjunctive normal form uses only the operators $+$, $\cdot$, and $'$;
- $\{+,\,'\}$ De Morgan's law $(a \cdot b)' = a' + b'$ allows the replacement of any occurrence of $a \cdot b$ with an expression that does not use $\cdot$;
- $\{\cdot\,,\,'\}$ De Morgan's law $a + b = (a' \cdot b')'$ allows the replacement of any occurrence of $a + b$ with an expression that does not use $+$;
- $\{|\}$ write the expression for any function in DNF; use $a' = a \,|\, a$, $a+b = (a\,|\,a)\,|\,(b\,|\,b)$, and $a \cdot b = (a\,|\,b)\,|\,(a\,|\,b)$ to replace each occurrence of $'$, $+$, and $\cdot$ with $|$;
- $\{\downarrow\}$ write the expression for any function in DNF; use $a' = a \downarrow a$, $a + b = (a \downarrow b) \downarrow (a \downarrow b)$, and $a \cdot b = (a \downarrow a) \downarrow (b \downarrow b)$ to replace each occurrence of $'$, $+$, and $\cdot$ with $\downarrow$.

6. The set $\{+\,,\,\cdot\}$ is not functionally complete.

Examples:

1. The function $f\colon \{0,1\}^3 \to \{0,1\}$ defined by $f(x,y,z) = x(z' + y'z) + x'$ is a Boolean function in the Boolean variables x, y, z. Multiplying out the expression for this function yields $f(x,y,z) = xz' + xy'z + x'$. In this form the second term, $xy'z$, is a minterm in the three variables x, y, z. The first and third terms are not minterms: the first term, xz', does not use a literal for y, and the third term, x', does not use literals for y and z.

2. *Writing a Boolean function in disjunctive normal form*: To write the function f from Example 1 in DNF using Fact 3(a), replace the terms xz' and x' with equivalent minterms by multiplying these terms by 1 $(= a + a')$ for each missing variable a:

$$xz' = xz' \cdot 1 = xz'(y + y') = xyz' + xy'z';$$
$$x' = x' \cdot 1 \cdot 1 = x'(y + y')(z + z') = x'yz + x'yz' + x'y'z + x'y'z'.$$

Therefore,

$$\begin{aligned} f(x,y,z) &= x(z'+y'z)+x' \\ &= xz'+xy'z+x' \\ &= xyz'+xy'z'+xy'z+x'yz+x'yz'+x'y'z+x'y'z'. \end{aligned}$$

Alternatively, using Fact 3(b), the table of values for f yields 1 in all rows except the row in which $x=y=z=1$. Therefore minterms are obtained for the other rows, yielding the same sum of seven minterms.

3. *Writing a Boolean function in conjunctive normal form*: Using Fact 4(a) to write the function $f(x,y)=xy'+x'y$ in CNF, first rewrite the negation of f in DNF, obtaining $f'(x,y)=xy+x'y'$. The negation of f' is $f''(x,y)=f(x,y)=(x'+y')(x+y)$.

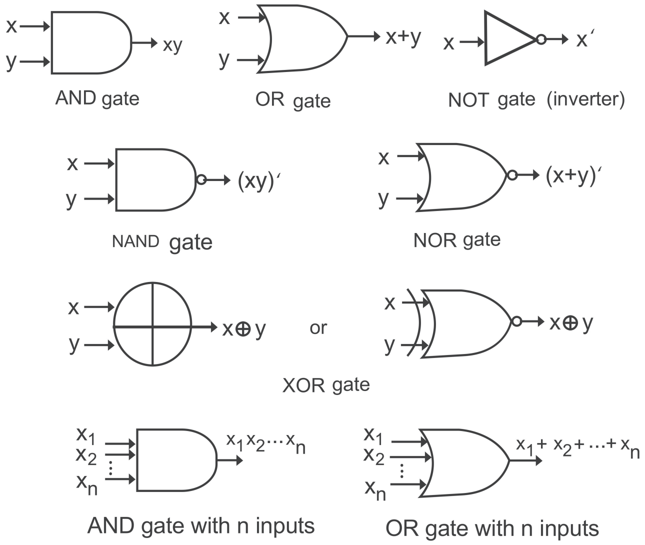
Alternatively, using Fact 4(c), the function f has value 0 only when $x=y=1$ and $x=y=0$. The maxterms that yield 0 in exactly one of these rows are $x'+y'$ and $x+y$. This yields the CNF $f(x,y)=(x'+y')(x+y)$.

5.8.3 LOGIC GATES

Boolean algebra can be used to model circuitry, with 0s and 1s as inputs and outputs. The elements of these circuits are *gates* that implement the Boolean operations.

Facts:

1. The following figure gives representations for the three standard Boolean operators, $+$, $\cdot$, and $'$, together with representations for three related operators. (For example, the AND gate takes two inputs, x and y, and produces one output, xy.)



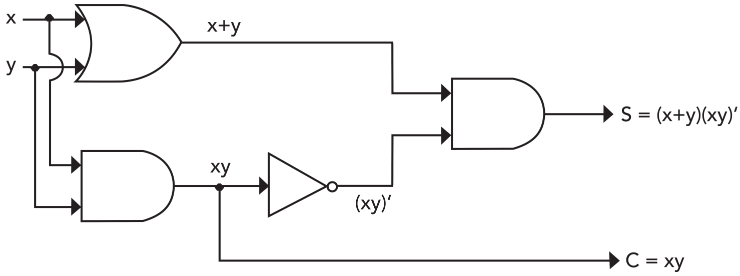
2. Gates can be extended to include cases where there are more than two inputs. The figure of Fact 1 also shows an AND gate and an OR gate with multiple inputs. These correspond to $x_1x_2\dots x_n$ and $x_1+x_2+\cdots+x_n$. (Since both operations satisfy the associative laws, no parentheses are needed.)

Examples:

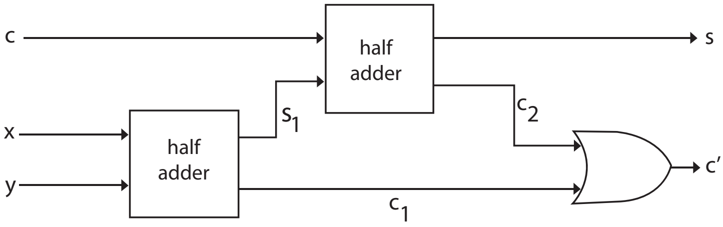
1. *The gate diagram for a half-adder*: A *half-adder* is a Boolean circuit that adds two bits, x and y, producing two outputs:

a *sum bit* $s = (x + y)(xy)'$ ($s = 0$ if $x = y = 0$ or $x = y = 1$; $s = 1$ otherwise);
a *carry bit* $c = xy$ ($c = 1$ if and only if $x = y = 1$).

The gate diagram for a half-adder is given in the following figure. This circuit is an example of a *multiple output circuit* since there is more than one output.



2. *The gate diagram for a full-adder*: A *full-adder* is a Boolean circuit that adds three bits (x, y, and a carry bit c) and produces two outputs (a sum bit s and a carry bit c'). The full-adder gate diagram is given in the following figure.



5.8.4 MINIMIZATION OF CIRCUITS

Boolean expressions that appear to be different can yield the same combinatorial circuit. For example, $xyz + xyz' + x'y$ and y (as functions of x and y) have the same table of values and hence yield the same circuit. (The first expression can be simplified to give the second: $xyz+xyz'+x'y = xy(z+z')+x'y = xy\cdot 1+x'y = xy+x'y = (x+x')y = 1\cdot y = y$.)

Definitions:

A Boolean expression is ***minimal*** (as a sum-of-products) if among all equivalent sum-of-products expressions it has the fewest number of summands, and among all sum-of-products expressions with that number of summands it uses the smallest number of literals in the products.

A ***Karnaugh map*** for a Boolean expression written in disjunctive normal form is a diagram (constructed using the following algorithm) that displays the minterms in the Boolean expression.

Facts:

1. Minimization of circuits is an NP-hard problem.

2. *Don't care conditions*: In some circuits, it may be known that some elements of the input set for the Boolean function will never be used. Consequently, the values of the expression for these elements is irrelevant. The values of the circuit function for these unused elements of the input set are called *don't care conditions*, and the values can be arbitrarily chosen to be 0 or 1. The blocks in the Karnaugh map where the function values are irrelevant are marked with d. In the simplification process of the Karnaugh map, 1s can be substituted for any or all of the ds in order to cover larger blocks of boxes and achieve a simpler equivalent expression.

Algorithm:

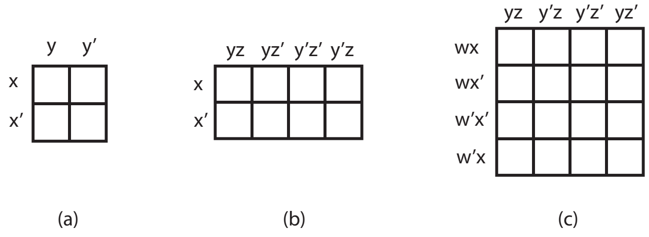
There is an algorithm for minimizing Boolean expressions by systematically grouping terms together. When carried out visually, the method uses a Karnaugh map (Maurice Karnaugh, born 1924). When carried out numerically using bit strings, the method is called the Quine-McCluskey method (Willard Quine, 1908–2000; Edward McCluskey, 1929–2016).

1. *Karnaugh map method*:

(a) Write the Boolean expression in disjunctive normal form.

(b) Obtain the Karnaugh map for this Boolean expression. The layout of the table depends on the number of variables under consideration.

The grids for Boolean expressions with two variables (x and y), three variables (x, y, and z), and four variables (w, x, y, and z) are shown in the following figure. Each square in each grid corresponds to exactly one minterm—the product of the row heading and the column heading. For example, the upper right box in the grid of part (a) of the figure represents the minterm xy'; the lower right box in the grid of part (c) of the figure represents $w'xyz'$.



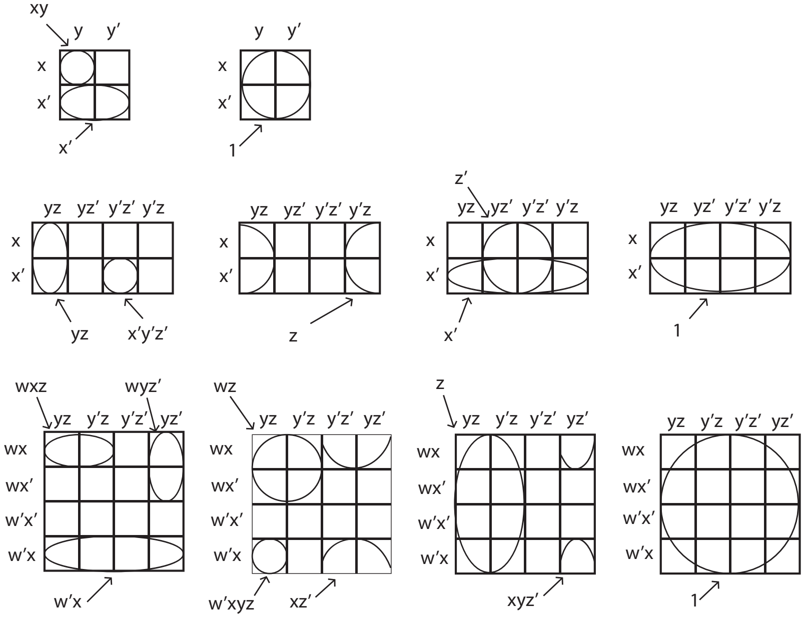
(a) (b) (c)

The headings are placed in a certain order—adjacent squares in any row (or column) differ in exactly one literal in their row headings (or column headings). The first and last squares in any row (or column) are to be regarded as adjacent. (The variable names can be permuted; for example, in part (b) of the figure, the row headings can be y and y' and the column headings can be xz, xz', $x'z'$, and $x'z$. The column headings could also have been written in order as yz, $y'z$, $y'z'$, yz' or $y'z$, $y'z'$, yz', yz.)

The Karnaugh map for the Boolean expression is obtained by placing a checkmark in each square corresponding to a minterm in the expression.

(c) Find the best covering. A geometric version of the distributive law is used to "cover" groups of the adjacent marked squares, with every marked square covered at least once and each group covered being as large as possible. The possible ways of covering squares depends on the number of variables.

(For example, working with two variables and using the distributive law, $x'y + x'y' = x'(y + y') = x'1 = x'$. This corresponds to covering the two boxes in the bottom row of the first 2×2 grid in the following figure and noting that the only literal common to both boxes is x'.



Similarly, working with three variables, $xyz' + xy'z' + x'yz' + x'y'z' = xz'(y + y') + x'z'(y + y') = xz' + x'z' = (x + x')z' = z'$. This corresponds to covering the four boxes in the second and third columns of the third 2×4 grid in the second row of the figure and noting that z' is the only common literal.)

The following table shows what groups of boxes can be covered, for expressions with 2, 3, and 4 variables. These are the combinations whose expressions can be simplified to a single minterm. Examples for 2, 3, and 4 variables are shown in the previous figure. (The method is awkward to use when there are more than 4 variables.)

# variables	*groups of boxes that can be covered*
2	1×1, 1×2, 2×1, 2×2
3	1×1, 1×2, 1×4, 2×1, 2×2, 2×4
4	1×1, 1×2, 1×4, 2×1, 2×2, 2×4, 4×1, 4×2, 4×4

To obtain the minimization, cover boxes according to the following rules:

- cover all marked boxes at least once;
- cover the largest possible blocks of marked boxes;
- do not cover any unmarked box;
- use the fewest blocks possible.

(d) Find the product of common literals for each of the blocks and form the sum of these products to obtain the minimization.

2. *Quine-McCluskey method*:

(a) Write the Boolean expression in disjunctive normal form, and in each summand list the variables in alphabetical order. Identify with each term a bit string, using a 1 if the literal is not a complement and 0 if the literal is a complement. (For example, $v'wx'yz$ is represented by 01011.)

(b) Form a table with the following columns:

column 1: Make a numbered list of the terms and their bit strings, beginning with the terms with the largest number of uncomplemented variables. (For example, $wxy'z$ precedes $wx'yz'$.)

column 2: Make a list of pairs of terms from column 1 where the literals in the two terms differ in exactly one position. Use a distributive law to add and simplify the two terms and write the numbers of these terms and the sum of the terms in the second column, along with its bit string, using "−" in place of the variable that no longer appears in the sum. (For example, xyz' and $xy'z'$ can be combined to yield xz' with bit string $1{-}0$.)

columns 3, 4, *etc.*: To obtain column 3 combine the terms in column 2 in pairs according to the same procedure as that used to construct column 2. Repeat this process until no more terms can be combined.

(c) Form a table with a row for each of the terms that cannot be used to form terms with fewer variables and a column for each of the original terms in the disjunctive normal form of the original expression. Mark the square in the ij-position if the minterm in column j could be a summand for the term in row i.

(d) Find a set of rows, with as few rows as possible, such that every column has been marked at least once in at least one row. The sum of the products labeling these rows minimizes the original expression.

Examples:

1. Simplify $w'x'y + w'z(xy + x'y') + w'x'z' + w'xyz' + wx'y'z'$ (an expression in four variables) using a Karnaugh map.

First write the expression in disjunctive normal form:

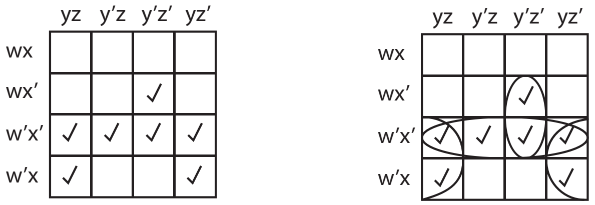
$$\begin{aligned} &w'x'y + w'z(xy + x'y') + w'x'z' + w'xyz' + wx'y'z' \\ &\qquad = w'x'yz + w'x'yz' + w'xyz + w'x'y'z + w'x'yz' + w'x'y'z' + w'xyz' + wx'y'z' \\ &\qquad = w'x'yz + w'x'yz' + w'xyz + w'x'y'z + w'x'y'z' + w'xyz' + wx'y'z'. \end{aligned}$$

Next, draw its Karnaugh map. See part (a) of the following figure. A covering is given in part (b) of the figure. Note that in order to use larger blocks, some squares have been covered more than once. Also note that $w'x'yz$, $w'xyz$, $w'x'yz'$, and $w'xyz'$ are covered with one 2×2 block rather than with two 1×2 blocks. In the three blocks the common literals are $w'x'$, $w'y$, and $x'y'z'$.

Finally, form the sum of these products: $w'x' + w'y + x'y'z'$.

2. Minimize $w'xy'z + wxyz' + wx'yz' + w'x'yz + wxyz + w'x'y'z + w'xyz$ (an expression in four variables) using the Quine-McCluskey method.

Step (b) of the Quine-McCluskey method yields the table that follows.



(a)

(b)

1	$wxyz$	1111	$1,2$	wxy	111−	$3,5,6,7$	$w'z$	0−−1
2	$wxyz'$	1110	$1,3$	xyz	−111			
3	$w'xyz$	0111	$2,4$	wyz'	1−10			
4	$wx'yz'$	1010	$3,5$	$w'yz$	0−11			
5	$w'x'yz$	0011	$3,6$	$w'xz$	01−1			
6	$w'xy'z$	0101	$5,7$	$w'x'z$	00−1			
7	$w'x'y'z$	0001	$6,7$	$w'y'z$	0−01			

The four terms $w'z$, wxy, xyz, wyz' were not used in combining terms, so they become the names of the rows in the next table:

	$wxyz$	$wxyz'$	$w'xyz$	$wx'yz'$	$w'x'yz$	$w'xy'z$	$w'x'y'z$
$w'x$			$\surd$		$\surd$	$\surd$	$\surd$
wxy	$\surd$	$\surd$					
xyz	$\surd$		$\surd$				
wyz'		$\surd$		$\surd$			

There are two ways to cover the seven minterms:

$$w'x, wxy, wyz' \quad \text{or} \quad w'x, xyz, wyz'.$$

This yields two ways to minimize the original expression:

$$w'x + wxy + wyz' \quad \text{and} \quad w'z + xyz + wyz'.$$

LINEAR ALGEBRA

INTRODUCTION

Concepts from linear algebra play an important role in various applications of discrete mathematics, as in coding theory, computer graphics, marketing, generation of pseudorandom numbers, graph theory, and combinatorial designs. This chapter discusses fundamental concepts of linear algebra, computational aspects, and various applications.

GLOSSARY

access (of a class): The class C_i of vertices has access to class C_j if either $i = j$ or there is a path from a vertex in C_i to a vertex in C_j.

adjacency matrix (of a graph): a square $(0, 1)$-matrix whose (i, j) entry is 1 if and only if vertices i and j are adjacent.

adjoint: See *Hermitian adjoint.*

algebraic multiplicity: given an eigenvalue, the multiplicity of the eigenvalue as a root of the characteristic equation.

augmented matrix (of a linear system): the matrix obtained by appending the right-hand side vector to the coefficient matrix as its rightmost column.

back substitution: a procedure for solving an upper triangular linear system.

basic class (of a matrix): a class such that the Perron root of the corresponding principal submatrix equals that of the entire matrix.

basis: an independent spanning set of vectors in a vector space.

characteristic equation: for a square matrix A, the equation $p_A(\lambda) = 0$, where $p_A(\lambda)$ is the characteristic polynomial of A.

characteristic polynomial: for a square matrix A, the polynomial (in the indefinite symbol λ) given by $p_A(\lambda) = \det(\lambda I - A)$.

Cholesky decomposition: expressing a matrix A as $A = LL^T$, where L is lower triangular and every entry on the main diagonal of L is positive.

circulant: a matrix in which every row is obtained by a single cyclic shift of the previous row.

class (of a matrix): a maximal set of row indices such that the corresponding vertices have mutual access in the directed graph of the matrix.

complete pivoting: an implementation of Gaussian elimination in which a pivot of largest magnitude is selected at each step.

completion (of a partially specified matrix): a matrix in which values are chosen for each unspecified entry.

condition number: given a matrix A, the number $\kappa(A) = \|A\| \, \|A^{-1}\|$.

conjugate sequence (of a sequence): the sequence whose nth term is the number of terms not less than n in the given sequence.

dependent set: a set of vectors in a vector space that are not independent.

determinant: given an $n \times n$ matrix A, $\det A = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma)\, a_{1\sigma(1)} a_{2\sigma(2)} \ldots a_{n\sigma(n)}$, where S_n is the symmetric group on n elements and the coefficient $\operatorname{sgn}(\sigma)$ is the sign of the permutation σ: 1 if σ is an even permutation and -1 if σ is an odd permutation.

diagonal matrix: a square matrix with nonzero elements only on the main diagonal.

diagonalizable matrix: a square matrix that is *similar* to a diagonal matrix.

difference (of matrices of the same dimensions): the matrix each of whose elements is the difference between corresponding elements of the original matrices.

dimension: for a vector space V, the number of vectors in any basis for V.

directed graph (of a matrix A): the graph $G(A)$ with vertices corresponding to the rows of A and an edge from i to j whenever a_{ij} is nonzero.

direct sum (of subspaces): given subspaces U and W, the sum of subspaces in which U and W have only the zero vector in common.

distance (between vectors): given vectors v and w, the length of the vector $v - w$.

dominant eigenvalue: given a matrix, an eigenvalue of the matrix of maximum modulus.

dot product (of real vectors): given real vectors $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_n)$, the number $x \cdot y = \sum\limits_{i=1}^{n} x_i y_i$.

doubly stochastic matrix: a matrix with all entries nonnegative and with all row and column sums equal to 1.

eigenvalue: given a square matrix A, a scalar λ such that $Ax = \lambda x$ for some nonzero vector x.

eigenvector: given a square matrix A, a nonzero vector x such that the vector Ax is a scalar multiple of x.

eigenspace: given a square matrix A, the vector space $\{\, x \mid Ax = \lambda x \,\}$ for some scalar λ.

exponent (of a matrix): given a matrix A, the least positive integer m, if it exists, such that A^m has all positive entries.

fill: in Gaussian elimination, those nonzero entries created in the triangular factors of a matrix corresponding to zero entries in the original matrix.

final class: given a matrix, a class of the matrix with access to no other class.

flop: a multiply-add operation involving a single multiplication followed by a single addition.

forward substitution: a procedure for solving a lower triangular linear system.

fully indecomposable matrix: a matrix that is not partly decomposable.

Gaussian elimination: a solution procedure that at each step uses one equation to eliminate one variable from the system of equations.

geometric multiplicity: the dimension of the eigenspace.

Geršgorin discs: regions in the complex plane that collectively are guaranteed to contain all the eigenvalues of a given matrix.

growth factor: a ratio that measures how large the entries of a matrix become during Gaussian elimination.

Hermitian adjoint: given a matrix A, the matrix A^* obtained from the transpose A^T by replacing each entry by its complex conjugate.

Hermitian matrix: a complex matrix whose transpose is its (elementwise) complex conjugate.

idempotent matrix: a matrix A such that $A^2 = A$.

identity matrix: a diagonal matrix in which each diagonal element is 1.

ill-conditioned system: a linear system $Ax = b$ whose solution x is extremely sensitive to errors in the data A and b.

independent set: a set of vectors in a vector space that is not dependent.

index of cyclicity: for a matrix, the number of eigenvalues with maximum modulus.

inner product: a field-valued function of two vector variables used to define a notion of orthogonality (that is, perpendicularity). In real or complex vector spaces it is also used to introduce length, distance, and convergence.

inverse: given a square matrix A, the square matrix A^{-1} whose product with the original matrix is the identity matrix.

invertible matrix: a matrix that has an inverse.

irreducible matrix: a matrix that is not reducible.

isomorphic (vector spaces): vector spaces that are structurally identical.

kernel (of a linear transformation): the set of all vectors that are mapped to the zero vector by the linear transformation.

Laplacian matrix (of a graph): the difference between the diagonal matrix associated with the graph (having vertex degrees on the diagonal) and the adjacency matrix of the graph.

length (of a vector): the square root of the inner product of the vector with itself.

linear combination (of vectors): given vectors $v_1, v_2, \ldots, v_t$, a vector of the form $a_1v_1 + a_2v_2 + \cdots + a_tv_t$, where the a_i are scalars.

linear operator: a linear transformation from a vector space to itself.

linear system: a set of m linear equations in n variables x, represented by $Ax = b$; here A is the coefficient matrix and b is the right-hand side vector.

linear transformation: a function T from one vector space over F to another vector space over F satisfying $T(au+v) = aT(u)+T(v)$ for all vectors u, v and all scalars a.

lower triangular matrix: a matrix in which all nonzero elements occur either on or below the diagonal.

LU decomposition: expressing a matrix A as the product $A = LU$, where L is unit lower triangular and U is upper triangular.

Markowitz pivoting: a simple greedy strategy for reducing the number of nonzero entries introduced during the LU decomposition of a sparse matrix.

matrix (of a linear transformation): given a linear transformation T, a matrix associated with T that represents T with respect to a fixed basis.

minimal polynomial: for a matrix A, the monic polynomial $q(\cdot)$ of minimum degree such that $q(A) = 0$.

minimum degree algorithm: a version of the Markowitz pivoting strategy for symmetric coefficient matrices.

minor: the determinant of a square submatrix of a given matrix.

modulus: the absolute value of a complex number.

nilpotent matrix: a matrix A such that $A^k = 0$ for some positive integer k.

nonnegative matrix: a matrix with each entry nonnegative.

nonsingular matrix: a matrix that has an inverse.

normal matrix: a matrix A such that $AA^* = A^*A$ (A^* is the Hermitian adjoint of A).

nullity (of a linear transformation): the dimension of the kernel of the linear transformation.

nullity (of a matrix): the dimension of the null space of the matrix.

null space (of a matrix A): the set of all vectors x for which $Ax = 0$.

numerically stable algorithm: an algorithm whose accuracy is not greatly harmed by roundoff errors.

numerically unstable algorithm: an algorithm that can return an inaccurate solution even when the solution is relatively insensitive to errors in the data.

orthogonal matrix: a real square matrix whose inverse is its transpose.

orthogonal set (of vectors): a set of vectors in which any two distinct vectors have inner product 0.

orthonormal set (of vectors): a set of unit length orthogonal vectors.

partial pivoting: an implementation of Gaussian elimination which at step k selects the pivot of largest magnitude in column k.

partly decomposable (matrix): an $n \times n$ matrix containing a zero submatrix of size $k \times (n-k)$ for some $1 \leq k \leq n-1$.

permanent (of an $n \times n$ matrix A): $\text{per}(A) = \sum_{\sigma \in S_n} a_{1\sigma(1)} a_{2\sigma(2)} \ldots a_{n\sigma(n)}$, where S_n is the symmetric group on n elements.

permutation matrix: a square $(0,1)$-matrix in which the entry 1 occurs exactly once in each row and exactly once in each column.

Perron root: the spectral radius of a nonnegative matrix.

pivot: the coefficient of the eliminated variable in the equation used to eliminate it.

positive definite matrix: a Hermitian matrix A such that $x^*Ax > 0$ for all $x \neq 0$.

positive matrix: a matrix with each entry positive.

positive semidefinite matrix: a Hermitian matrix A such that $x^*Ax \geq 0$ for all x.

power (of a square matrix): the square matrix obtained by multiplying the matrix by itself the required number of times.

primitive matrix: a matrix with a finite exponent.

principal minor (of a matrix): the determinant of a principal submatrix of the matrix.

principal submatrix (of a matrix A): the matrix obtained from A by deleting all but a specified set of rows and the same set of columns.

product (of matrices): for an $m \times n$ matrix A and an $n \times p$ matrix B, the $m \times p$ matrix AB whose ij-entry is the scalar product of row i of A and column j of B.

range (of a linear transformation T): the set of all vectors w for which $T(v) = w$ has a solution.

rank (of a linear transformation T): the dimension of the range of T.

rank (of a matrix): the maximum number of linearly independent rows (or columns) in the matrix.

reducible matrix: a matrix A with $a_{ij} = 0$ for all $i \in S$, $j \notin S$, for some set S.

roundoff errors: the errors associated with storing and computing numbers in finite precision arithmetic on a digital computer.

row stochastic matrix: a matrix with all entries nonnegative and row sums 1.

scalar: an element of a field.

scalar multiple (of a matrix): the matrix obtained by multiplying each element of the original matrix by the scalar.

scalar product: See *dot product*.

sign pattern (of a matrix): the matrix obtained by replacing each entry of the given matrix by its sign (0, 1, or -1).

similar matrices: square matrices A and B satisfying the equation $P^{-1}BP = A$ for some invertible matrix P.

singular matrix: a matrix that has no inverse.

singular value decomposition (of a matrix A): the representation $A = U\Sigma V^T$, where U, V are orthogonal matrices and Σ is a diagonal matrix.

singular values (of a matrix A): the positive square roots of the eigenvalues of AA^*, where A^* is the Hermitian adjoint of A.

skew-Hermitian matrix: a matrix equal to the negative of its Hermitian adjoint.

skew-symmetric matrix: a matrix equal to the negative of its transpose.

span (of a set of vectors): all vectors obtainable as linear combinations of the given vectors.

spanning set: a set of vectors in a vector space V whose span equals V.

sparse matrix: a matrix that has relatively few nonzero entries.

spectral radius (of a matrix): the maximum modulus of an eigenvalue of the matrix.

square matrix: a matrix having the same number of rows and columns.

strictly diagonally dominant matrix: a square matrix each of whose diagonal elements exceeds in modulus the sum of the moduli of all other elements in that row.

strictly totally positive matrix: a matrix with all minors positive.

submatrix (of a matrix A): the matrix obtained from A by deleting all but a certain set of rows and a certain set of columns.

subspace: a vector space within a vector space.

sum (of matrices): for two matrices of the same dimensions, the matrix each of whose elements is the sum of the corresponding elements of the original matrices.

sum (of subspaces): given subspaces U and W, the subspace consisting of all possible sums $u + w$ where $u \in U$ and $w \in W$.

symmetric matrix: a matrix that equals its transpose.

term rank (of a $(0,1)$-matrix): the maximum number of 1s such that no two are in the same row or column.

tournament matrix: a $(0,1)$-matrix $A = (a_{ij})$ with zero diagonal entries and whose off-diagonal entries satisfy $a_{ij} + a_{ji} = 1$.

trace: given a square matrix, the sum of the diagonal elements of the matrix.

transpose (of a matrix): for a matrix A, the matrix A^T whose columns are the rows of the original matrix.

tridiagonal matrix: a matrix whose nonzero entries are either on the main diagonal or immediately above or below the main diagonal.

unitary matrix: a square matrix whose inverse is its Hermitian adjoint.

unit triangular matrix: a (lower or upper) triangular matrix having all diagonal entries 1.

upper triangular matrix: a matrix in which all nonzero elements occur either on or above the main diagonal.

vector: an individual object of a vector space.

vector space: a collection of objects that can be added and multiplied by scalars, always yielding another object in the collection.

well-conditioned system: a linear system $Ax = b$ whose solution x is relatively insensitive to errors in the data A and b.

$(0,1)$*-matrix*: a matrix with each entry either 0 or 1.

6.1 VECTOR SPACES

The concept of a "vector" comes initially from the physical world, where a vector is a quantity having both magnitude and direction (for example, force and velocity). The mathematical concept of a vector space generalizes these ideas, with applications in coding theory, finite geometry, cryptography, and other areas of discrete mathematics.

6.1.1 BASIC CONCEPTS

Definitions:

A ***vector space*** over a field F (§5.6.1) is a triple $(V, \oplus, \cdot)$ consisting of a set V and two operations, $\oplus$ (vector addition) and $\cdot$ (scalar multiplication), such that

- $(V, \oplus)$ is an abelian group (§5.2.1); i.e., $\oplus$ is a function $(u, v) \rightarrow u \oplus v$ from $V \times V$ to V satisfying

- ◇ $(u \oplus v) \oplus w = u \oplus (v \oplus w)$ for all $u, v, w \in V$;
- ◇ there is a vector 0 such that $v \oplus 0 = v$ for all $v \in V$;
- ◇ for each $v \in V$ there is $-v \in V$ such that $v \oplus (-v) = 0$;
- ◇ $u \oplus v = v \oplus u$ for all $u, v \in V$;

- the operation $\cdot$ is a function $(a, v) \to a \cdot v$ from $F \times V$ to V such that for all $a, b \in F$ and $u, v \in V$ the following properties hold:
  - ◇ $a \cdot (b \cdot v) = (ab) \cdot v$;
  - ◇ $(a + b) \cdot v = (a \cdot v) \oplus (b \cdot v)$;
  - ◇ $a \cdot (u \oplus v) = (a \cdot u) \oplus (a \cdot v)$;
  - ◇ $1 \cdot v = v$.

Here, ab and $a + b$ represent multiplication and addition of elements $a, b \in F$.

The ***scalars*** are the elements of F, the ***vectors*** are the elements of V, and the set V itself is often also called the ***vector space***.

The ***difference*** of two vectors u and v is the vector $u - v = u \oplus (-v)$ where $-v$ is the negative of v in the abelian group $(V, \oplus)$.

Notation: While vector addition $\oplus$ and field addition $+$ can be quite different, it is customary to use the same notation $+$ for both. It is also customary to write av instead of $a \cdot v$, and to use the symbol 0 for the additive identities of the vector space V and the field F.

Facts:

Assume that V is a vector space over F.

1. $a0 = 0$ and $0v = 0$ for all $a \in F$ and $v \in V$.

2. $(-1)v = -v$ for all $v \in V$.

3. If $av = 0$ for $a \in F$ and $v \in V$, then either $a = 0$ or $v = 0$.

4. *Cancellation property*: For all $u, v, w \in V$, if $u + v = w + v$, then $u = w$.

5. $a(u - v) = au - av$ for all $a \in F$ and $u, v \in V$.

Examples:

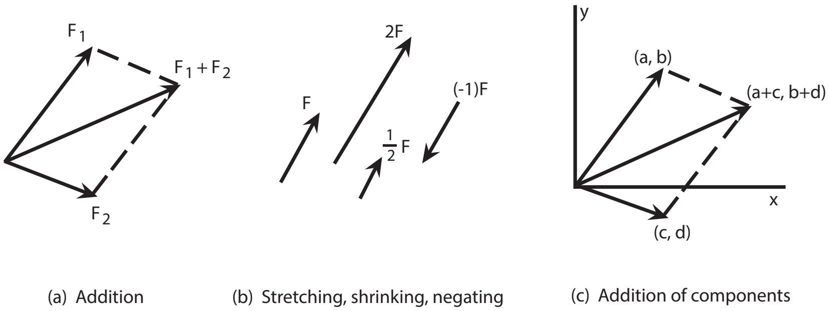
1. *Force vectors*: Forces in the plane can be represented by geometric vectors such as F_1 and F_2 in part (a) of the following figure; addition of these vectors is carried out using the so-called parallelogram law. By introducing a coordinate system and locating the initial point of each directed line segment at the origin $(0, 0)$, each geometric vector can be named by its terminal point. Thus, a vector in the plane becomes a pair $(x, y) \in \mathcal{R}^2$ of real numbers. The parallelogram law of addition translates into componentwise addition (part (c) of the figure), while stretching (respectively, shrinking, negating) translates to componentwise multiplication by a real number $r > 1$ (respectively, $0 < r < 1$, $r = -1$). Three-dimensional force vectors are similarly represented using triples $(x, y, z) \in \mathcal{R}^3$.

2. *Euclidean space*: Generalizing Example 1, n-dimensional Euclidean space consists of all n-tuples of real numbers $\mathcal{R}^n = \{ (x_1, x_2, \ldots, x_n) \mid x_i \in \mathcal{R} \}$.

3. If F is any field, then $F^n = \{ (x_1, x_2, \ldots, x_n) \mid x_i \in F \}$ is a vector space, where addition and scalar multiplication are componentwise:

$$\begin{aligned} (x_1, x_2, \ldots, x_n) + (y_1, y_2, \ldots, y_n) =& (x_1 + y_1, x_2 + y_2, \ldots, x_n + y_n) \\ a(x_1, x_2, \ldots, x_n) =& (ax_1, ax_2, \ldots, ax_n), \end{aligned}$$

where $a \in F$. When $F = \mathcal{R}$, these are the vectors mentioned in Examples 1 and 2.



(a) Addition (b) Stretching, shrinking, negating (c) Addition of components

4. *A vector space over $\mathcal{Z}_2$*: V consists of the 128 subsets of the set $\{1, 2, \ldots, 7\}$ as represented by binary 7-tuples; for example, the subset $\{1, 4, 5, 7\}$ corresponds to $(1, 0, 0, 1, 1, 0, 1)$ and the subset $\{1, 2, 3, 4\}$ to $(1, 1, 1, 1, 0, 0, 0)$. The operations on V are componentwise addition and scalar multiplication mod 2. In this vector space, the sum of two members of V corresponds to the symmetric difference (§1.2.2) of the associated sets. (This example is a special case of Example 3.)

5. *A finite affine plane over $\mathcal{Z}_5$*: V consists of all pairs (x, y) where $x, y \in \mathcal{Z}_5$ and where addition and scalar multiplication are componentwise modulo 5. This special case of Example 3 arises in finite geometry where the 25 members of V are thought of as "points" and the sets of solutions to equations of the form $ax + by = c$ (where $a, b, c \in \mathcal{Z}_5$ with one of a or $b \neq 0$) are viewed as "lines".

6. *Infinite binary sequences*: V consists of all infinite binary sequences $\{ (s_1, s_2, \ldots) \mid s_i \in \mathcal{Z}_2 \}$ where addition and multiplication are componentwise mod 2. As in Example 4, each $s \in V$ may be viewed as a subset of the positive integers, but each s may also be viewed as a potential "message" or "data" stream; for example, each group of 7 consecutive members of s could represent a letter in the 7-bit ASCII code.

7. $V = F^{m \times n}$, the set of all $m \times n$ matrices over F, is a vector space, where vector addition is the usual matrix addition and scalar multiplication is the usual scalar-by-matrix multiplication (§6.3.2). When $m = 1$, this reduces to Example 3.

8. Let $V = E$ be a field and F a subfield. Then V is a vector space over F where vector addition and scalar multiplication are the addition and multiplication of E. In particular, the finite field F_q of prime power order $q = p^n$ is a vector space over the subfield F_p.

9. Let $V = F[x]$, the set of all polynomials (§5.5.2) over F in an indeterminate x. Then V is a vector space over F, where addition is ordinary polynomial addition and scalar multiplication is the usual scalar-by-polynomial multiplication.

10. For a nonempty set X and a given vector space U over F, let V denote the set of all functions from X to U. The sum $f + g$ of two vectors (functions) $f, g \in V$ is defined by $(f + g)(x) = f(x) + g(x)$ for all $x \in X$ and the scalar multiplication af of $a \in F$ by $f \in V$ is defined by $(af)(x) = af(x)$. (For specific cases of this general vector space, see §6.1.2, Examples 13–15.)

6.1.2 SUBSPACES

Definitions:

A ***subspace*** of a vector space V is a nonempty subset W of V that is a vector space under the addition and scalar multiplication operations inherited from V.

The ***sum*** of two subspaces $U, W \subseteq V$ is the set $\{\, u+w \mid u \in U,\ w \in W \,\}$. If $U \cap W = \{0\}$, their sum is called the ***direct sum***, denoted $U \oplus W$.

If A is an $m \times n$ matrix over F, the ***null space*** $NS(A)$ of A is $\{\, x \in F^{n\times 1} \mid Ax = 0 \,\}$. The null space of A is also called the ***right null space*** when contrasted with the ***left null space*** $LNS(A)$ defined by $\{\, y \in F^{1\times m} \mid yA = 0 \,\}$.

Facts:

Assume that V is a vector space over F.

1. $W \subseteq V$ is a subspace of V if and only if $W \neq \emptyset$ and for all $a, b \in F$ and $u, v \in W$, $au + bv \in W$.

2. $W \subseteq V$ is a subspace of V if and only if $W \neq \emptyset$ and for all $a \in F$ and $u, v \in W$, $u + v \in W$ and $au \in W$.

3. Every subspace of V contains 0, the zero vector.

4. The sets $\{0\}$ and V are subspaces of V.

5. The intersection of any collection of subspaces of V is a subspace of V.

6. The sum of any collection of subspaces of V is a subspace of V.

7. Each member of $U \oplus W$ can be expressed as a sum $u + w$ for a unique $u \in U$ and a unique $w \in W$.

8. The set of solutions to a homogeneous linear equation in the unknowns $x_1, x_2, \ldots, x_n$ is a subspace of F^n. Namely, for any fixed $(a_1, a_2, \ldots, a_n) \in F^n$, the set $W = \{\, x \in F^n \mid a_1x_1 + a_2x_2 + \cdots + a_nx_n = 0 \,\}$ is a subspace of F^n.

9. The set of solutions to any collection of homogeneous linear equations in the unknowns $x_1, x_2, \ldots, x_n$ is a subspace of F^n. In particular, if W is a subspace of F^n then the set of all $x = (x_1, x_2, \ldots, x_n) \in F^n$ satisfying $a_1x_1 + a_2x_2 + \cdots + a_nx_n = 0$ for all $(a_1, a_2, \ldots, a_n) \in W$ is a subspace of V called the *orthogonal complement* of W and denoted $W^{\perp}$.

10. The null space $NS(A)$ of an $m \times n$ matrix A over F is a subspace of $F^{n\times 1}$.

11. The left null space $LNS(A)$ of an $m \times n$ matrix A is a subspace of $F^{1\times m}$ and equals $(NS(A^T))^T$ where T denotes transpose.

Examples:

1. The set of all 3-tuples of real numbers of the form $(a, b, 2a + 3b)$ where $a, b \in \mathcal{R}$ is a subspace of $\mathcal{R}^3$. This subspace can also be described as the set of solutions (x, y, z) to the homogeneous linear equation $2x + 3y - z = 0$.

2. The set of all 4-tuples of real numbers of the form $(a, -a, 0, b)$ where $a, b \in \mathcal{R}$ is a subspace of $\mathcal{R}^4$. This subspace can also be described as the set of solutions (x_1, x_2, x_3, x_4) to the pair of equations $x_1 + x_2 = 0$ and $x_3 = 0$.

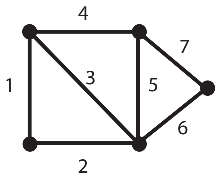
3. For $V = \mathcal{Z}_5^2$, the set of all solutions to the equation $x + 2y = 0$ forms a subspace. It consists of the finite set $\{(0,0), (3,1), (1,2), (4,3), (2,4)\}$ and can also be described as the set of all pairs in V of the form $(3a, a)$. The set S of solutions to $x + 2y = 1$, namely $\{(1,0), (4,1), (2,2), (0,3), (3,4)\}$, is not a subspace of V since for example $(1,0) + (4,1) = (0,1) \notin S$. However S is a “line” in the affine plane described in Example 5 of §6.1.1.

4. In the vector space $V = \mathcal{Z}_2^7$, the set of 7-tuples with an even number of 1s is a subspace. This subspace can also be described as the collection of all members of V whose components sum to 0.

5. *Coding theory*: In the vector space F^n over the finite field $F = GF(q)$, a linear code (§14.2) is simply any subspace of F^n. In particular, an (n, k)-code is a k-dimensional subspace of F^n.

6. *Binary codes*: A linear binary code is any subspace of the vector space F^n where F is the finite field on two elements, $GF(2)$. Generalizing Example 4, the set of all binary n-tuples with an even number of 1s is a subspace of F^n and so is a linear binary code.

7. Consider the undirected graph (§8.1) in the following figure, where the edges have been labeled with the integers $\{1, 2, \ldots, 7\}$. Associate with this graph the vector space $V = \mathcal{Z}_2^7$ where, as in Example 4 (§6.1.1), each binary 7-tuple is identified with a subset of edges. One subspace W of V, called the *cycle space* of the graph, corresponds to the (edge-disjoint) union of cycles in the graph. For example, $(1, 1, 0, 1, 0, 1, 1) \in W$ as it corresponds to the cycle $1, 2, 6, 7, 4$, and so is $(1, 1, 1, 0, 1, 1, 1)$ which corresponds to the edge-disjoint union of cycles $1, 2, 3$ and $5, 6, 7$. The sum of these two members of W is $(0, 0, 1, 1, 1, 0, 0)$ which corresponds to the cycle $3, 4, 5$.



8. The set of $n \times n$ symmetric matrices (§6.3.1) over a field F is a subspace of $F^{n \times n}$, and so is the set of $n \times n$ upper triangular matrices (§6.3.1) over F.

9. For an $m \times m$ matrix A over F and $\lambda \in F$, the set $W = \{\, X \in F^{m \times n} \mid AX = \lambda X \,\}$ is a subspace of $F^{m \times n}$. (This space is related to the *eigenspaces* of A discussed in §6.5.2.)

10. For a given $n \times n$ matrix A over F, the set $W = \{\, X \in F^{n \times n} \mid XA = AX \,\}$ is a subspace of $F^{n \times n}$. (This is the space of matrices that commute with A.)

11. Let field E be a vector space over subfield F, and let K denote the set of all elements $\alpha \in E$ that satisfy a polynomial equation of the form $f(\alpha) = 0$ for some nonzero $f(x) \in F[x]$. Then K is a subfield of E containing F (the field of *algebraic elements* of E over F) and consequently is a subspace of E over F. (See §5.6.2.)

12. For each fixed $n \geq 1$, the set of all polynomials of degree $\leq n$ is a subspace of $F[x]$. (See §6.1.1, Example 9.)

13. In Example 10 of §6.1.1, take $X = [a, b]$ where $a, b \in \mathcal{R}$ with $a < b$, and take $U = \mathcal{R}$ as a vector space over itself. The resulting V, the set of all real-valued functions on $[a, b]$, is a vector space. The set $C[a, b]$ of continuous real-valued functions on $[a, b]$ is a subspace of V.

14. In Example 10 of §6.1.1, take $X = \{1, 2, \ldots, 7\}$ and take $U = \mathcal{Z}_2$ as a vector space over itself. The resulting V, the set of all functions from $\{1, 2, \ldots, 7\}$ to $\mathcal{Z}_2$, can be thought of as the vector space of binary 7-tuples $V = \mathcal{Z}_2^7$.

15. In Example 10 of §6.1.1, take both X and U to be vector spaces over F. Then V is the vector space of all functions from X to U. The collection of those $T \in V$ satisfying $T(a\alpha + b\beta) = aT(\alpha) + bT(\beta)$ for all $a, b \in F$ and $\alpha, \beta \in X$ is a subspace of V. (This space is the space of *linear transformations* considered in §6.2.)

6.1.3 LINEAR COMBINATIONS, INDEPENDENCE, BASIS, AND DIMENSION

Definitions:

If $v_1, v_2, \ldots, v_t$ are vectors from a vector space V over F, then a vector $w \in V$ is a ***linear combination*** of $v_1, v_2, \ldots, v_t$ if $w = a_1v_1 + a_2v_2 + \cdots + a_tv_t$ for some scalars $a_i \in F$. The zero vector is considered a linear combination of $\emptyset$.

For $S \subseteq V$, the ***span*** of S, denoted $\text{Span}(S)$, is the set of all (finite) linear combinations of members of S; that is, $\text{Span}(S)$ consists of all finite sums $a_1v_1+a_2v_2+\cdots+a_tv_t$ where $v_i \in S$ and $a_i \in F$. (The span of the empty set is taken to be $\{0\}$.) $\text{Span}(S)$ is also called the space ***generated*** or ***spanned*** by S. (See Fact 1.)

The ***row space*** $RS(A)$ of an $m \times n$ matrix A over F (§6.3.1) is $\text{Span}(R_1, R_2, \ldots, R_m)$, where $R_1, R_2, \ldots, R_m$ are the rows of A viewed as vectors in $F^{1\times n}$.

The ***column space*** $CS(A)$ of A is $\text{Span}(C_1, C_2, \ldots, C_n)$, where $C_1, C_2, \ldots, C_n$ are the columns of A.

A subset $S \subseteq V$ is called a ***spanning set*** for V if $\text{Span}(S) = V$.

A subset $S \subseteq V$ is (***linearly***) ***independent*** if every finite subset $\{v_1, v_2, \ldots, v_t\}$ of S has the property that the only scalars $a_1, a_2, \ldots, a_t$ satisfying $a_1v_1+a_2v_2+\cdots+a_tv_t = 0$ are $a_1 = a_2 = \cdots = a_t = 0$.

A subset $S \subseteq V$ is (***linearly***) ***dependent*** if it is not independent.

A ***basis*** for V is an independent spanning set.

A vector space V is ***finite dimensional*** if it has a finite basis; otherwise, V is ***infinite dimensional***.

The ***dimension*** $\dim V$ of a vector space V is the cardinality of any basis for V. (See Fact 8.)

If $\mathcal{B} = (v_1, v_2, \ldots, v_n)$ is an ordered basis for V, then the ***coordinates*** of v with respect to $\mathcal{B}$ are the scalars $a_1, a_2, \ldots, a_n$ such that $v = a_1v_1 + a_2v_2 + \cdots + a_nv_n$. (See Fact 14.) The ***coordinate vector*** $[v]_{\mathcal{B}}$ of v with respect to $\mathcal{B}$ (written as a column) is $[v]_{\mathcal{B}} = (a_1, a_2, \ldots, a_n)^T$ where T denotes transpose (§6.3.1).

Note: Some writers distinguish between the coordinates written as a row and as a column, calling the row $(a_1, a_2, \ldots, a_n)$ the *coordinate vector* of v with respect to $\mathcal{B}$ and the column $(a_1, a_2, \ldots, a_n)^T$ the *coordinate matrix* of v with respect to $\mathcal{B}$.

The ***row rank*** of a matrix A over F is $\dim RS(A)$, and the ***column rank*** of A is $\dim CS(A)$. The ***rank*** of A is the size of the largest square submatrix of A with nonzero determinant (§6.3.4); that is, rank $A = r$ if there exists an $r \times r$ submatrix of A whose determinant is nonzero, and every $t \times t$ submatrix of A with $t > r$ has zero determinant.

The ***nullity*** of a matrix A is $\dim NS(A)$.

Two vector spaces V and U over the same field F are ***isomorphic*** if there exists a bijective mapping $T\colon V \to U$ such that $T(v + w) = T(v) + T(w)$ and $T(av) = aT(v)$ for all $v, w \in V$ and $a \in F$. The mapping T is called an ***isomorphism***.

Facts:

1. Span(S) is a subspace of V. In particular, $RS(A)$ is a subspace of $F^{1\times n}$ and $CS(A)$ is a subspace of $F^{m\times 1}$.

2. Span(S) is the intersection of all subspaces of V that contain S; thus, Span(S) is the smallest subspace of V containing S in that it lies inside every subspace of V containing S.

3. A set $\{v\}$ consisting of a single vector from V is dependent if and only if $v = 0$.

4. A set of two or more vectors is dependent if and only if some vector in the set is a linear combination of the remaining vectors in the set.

5. Any superset of a dependent set is dependent, and any subset of an independent set is independent. (The empty set is independent.)

6. If V has a basis of n elements, then every subset of V with more than n elements is dependent.

7. If W is a subspace of V then $\dim W \le \dim V$.

8. Every vector space V has a basis, and every two bases for V have the same number of elements (cardinality). For infinite-dimensional vector spaces, this fact relies on the *axiom of choice* (§1.2.4).

9. Every independent subset of V can be extended to a basis for V. More generally, if S is an independent set, then every maximal independent set containing S is a basis for V containing S. For infinite-dimensional vector spaces, this fact relies on the axiom of choice. (An independent set is *maximal* if every set properly containing it is dependent.)

10. Every spanning set contains a basis for V. More generally, if S is a spanning set, then every minimal spanning subset of S is a basis for V. For infinite-dimensional vector spaces, this fact relies on the axiom of choice. (A spanning set is *minimal* if it contains no proper subset that spans V.)

11. *Rank-nullity theorem*: If A is an $m \times n$ matrix over F then

- $\dim RS(A) + \dim NS(A) = n$;
- $\dim CS(A) + \dim NS(A) = n$;
- $\dim RS(A) + \dim LNS(A) = m$;
- $\dim CS(A) + \dim LNS(A) = m$.

12. For every matrix A, row rank A = column rank A = rank A. Thus, the (maximum) number of independent rows of A equals the (maximum) number of independent columns.

13. The set of solutions to the m homogeneous linear equations $\sum_{j=1}^{n} a_{ij}x_j = 0$ in n unknowns has dimension $n - r$, where r is the rank of the $m \times n$ coefficient matrix $A = (a_{ij})$.

14. If $\mathcal{B}$ is a basis for a vector space V (finite or infinite), then each $v \in V$ can be expressed as $v = a_1v_1 + a_2v_2 + \cdots + a_tv_t$, where $a_i \in F$ and $v_i \in \mathcal{B}$. If $v = b_1v_1 + b_2v_2 + \cdots + b_tv_t$ is another expression for v in terms of elements of $\mathcal{B}$ (where possibly some zero coefficients have been inserted to make the two expressions have equal length), then $a_i = b_i$ for $i = 1, 2, \ldots, t$. (If $\mathcal{B}$ is finite, this justifies the definition of the coordinate vector $[v]_{\mathcal{B}}$.)

15. If $\mathcal{B} = (v_1, v_2, \ldots, v_n)$ is an ordered basis for V, then the function $T\colon V \to F^{n\times 1}$ defined by $T(v) = [v]_{\mathcal{B}}$ is an isomorphism, so V is isomorphic to $F^{n\times 1}$.

16. Two vector spaces over F are isomorphic if and only if they have the same dimension.

Examples:

1. The vector space F^n has dimension n. The *standard basis* is the ordered basis $(e_1, e_2, \ldots, e_n)$ where e_i is the vector with 1 in position i and 0s elsewhere. (The spaces F^n, $F^{1\times n}$, and $F^{n\times 1}$ are isomorphic and are often identified and used interchangeably.)

2. The vector space $F^{m\times n}$ of $m \times n$ matrices over F has dimension mn; the *standard basis* is $\{\, E_{ij} \mid 1 \leq i \leq m,\ 1 \leq j \leq n \,\}$ where E_{ij} is the $m \times n$ matrix with a 1 in position (i, j) and 0s elsewhere. It is isomorphic to F^{mn}.

3. The subspace of $\mathcal{R}^3$ containing all 3-tuples of the form $(a, b, 2a + 3b)$ has dimension 2. One basis for this subspace is $\mathcal{B}_1 = ((1, 0, 2), (0, 1, 3))$ and another is $\mathcal{B}_2 = ((1, 1, 5), (1, -1, -1))$. The vector $w = (5, -1, 7)$ is in the subspace since $w = 5(1, 0, 2) + (-1)(0, 1, 3) = 2(1, 1, 5) + 3(1, -1, -1)$. The coordinate vector of w with respect to $\mathcal{B}_1$ is $(5, -1)^T$ and the coordinate vector of w with respect to $\mathcal{B}_2$ is $(2, 3)^T$.

4. If W is the subspace of $V = \mathcal{Z}_2^5$ containing all members of V whose components sum to 0, then W has dimension 4. In fact $W = \{\, (a, b, c, d, a + b + c + d) \mid a, b, c, d \in \mathcal{Z}_2 \,\}$. One ordered basis for this space is $((1, 0, 0, 0, 1), (0, 1, 0, 0, 1), (0, 0, 1, 0, 1), (0, 0, 0, 1, 1))$.

5. *Binary codes*: More generally, consider the set of all binary n-tuples with an even number of 1s; this is the linear binary code mentioned in Example 6, §6.1.2. These vectors form a subspace W of $V = \mathcal{Z}_2^n$ of dimension $n - 1$. A basis for W consists of the following $n - 1$ vectors, each of which has exactly two 1s: $(1, 0, \ldots, 1), (0, 1, \ldots, 1), \ldots, (0, 0, \ldots, 1, 1)$. Consequently there are 2^{n-1} vectors in the code W.

6. The field $\mathcal{C}$ of complex numbers is two-dimensional as a vector space over $\mathcal{R}$; it has the ordered basis $(1, i)$, where $i = \sqrt{-1}$. Any two complex numbers, neither of which is a real multiple of the other, form a basis.

7. Both $\mathcal{C}$ and $\mathcal{R}$ are infinite-dimensional vector spaces over the rational field $\mathcal{Q}$.

8. The vector space $F[x]$ is an infinite-dimensional space over F; $(1, x, x^2, x^3, \ldots)$ is an ordered basis. The subspace of all polynomials of degree $\leq n$ has dimension $n + 1$; $(1, x, x^2, \ldots, x^n)$ is an ordered basis.

6.1.4 INNER PRODUCTS, LENGTH, AND ORTHOGONALITY

By imposing additional structure on real and complex vector spaces, the concepts of length, distance, and orthogonality can be introduced. These concepts are motivated by the corresponding geometric notions for physical vectors. Also, for real vector spaces the geometric idea of angle can be formulated analytically.

Definitions:

An ***inner product*** on a vector space V over $\mathcal{R}$ is a function $\langle \cdot, \cdot \rangle \colon V \times V \to \mathcal{R}$ such that for all $u, v, w \in V$ and $a, b \in \mathcal{R}$ the following hold:

- $\langle u, v \rangle = \langle v, u \rangle$;
- $\langle u, u \rangle \geq 0$ with equality if and only if $u = 0$;
- $\langle au + bv, w \rangle = a\langle u, w \rangle + b\langle v, w \rangle$.

An ***inner product*** on a vector space V over $\mathcal{C}$ is a function $\langle \cdot, \cdot \rangle \colon V \times V \to \mathcal{C}$ such that for all $u, v, w \in V$ and $a, b \in \mathcal{C}$ the following hold:

- $\langle u, v \rangle = \overline{\langle v, u \rangle}$ (where bar denotes complex conjugation);
- $\langle u, u \rangle \geq 0$ with equality if and only if $u = 0$;

- $\langle au + bv, w\rangle = a\langle u, w\rangle + b\langle v, w\rangle$.

Note: The first property implies that $\langle u, u\rangle$ is real, so the second property makes sense.

An ***inner product space*** is a vector space over $\mathcal{R}$ or $\mathcal{C}$ on which an inner product is defined. Such a space is called a real or complex inner product space, depending on its scalar field.

The ***norm*** (***length***) of a vector $v \in V$ is $\|v\| = \sqrt{\langle v, v\rangle}$.

A vector $v \in V$ is a ***unit vector*** if and only if $\|v\| = 1$.

The ***distance*** $d(v, w)$ from v to w is $d(v, w) = \|v - w\|$.

In a real inner product space, the ***angle*** between nonzero vectors v and w is the real number θ, $0 \le \theta \le \pi$, such that $\cos\theta = \dfrac{\langle v, w\rangle}{\|v\| \cdot \|w\|}$.

Two vectors v and w are ***orthogonal*** if and only if $\langle v, w\rangle = 0$.

A subset $S \subseteq V$ is an ***orthogonal set*** if $\langle v, w\rangle = 0$ for all $v, w \in S$ with $v \ne w$.

A subset $S \subseteq V$ is an ***orthonormal set*** if S is an orthogonal set and $\|v\| = 1$ for all $v \in S$.

If W is a subspace of an inner product space V, then the ***orthogonal complement*** $W^{\perp} = \{\, v \in V \mid \langle v, w\rangle = 0 \text{ for all } w \in W \,\}$.

Facts:

1. *Standard inner product on* $\mathcal{R}^n$: The real-valued function defined by $\langle x, y\rangle = x_1y_1 + x_2y_2 + \cdots + x_ny_n$ is an inner product on $V = \mathcal{R}^n$.

2. *Standard inner product on* $\mathcal{C}^n$: The complex-valued function defined by $\langle x, y\rangle = x_1\overline{y}_1 + x_2\overline{y}_2 + \cdots + x_n\overline{y}_n$ is an inner product on $V = \mathcal{C}^n$.

3. If A is an $n \times n$ real positive definite matrix (§6.3.2), then the function defined by $\langle x, y\rangle = x^TAy$ is an inner product on $\mathcal{R}^n$. (Here x^T denotes the transpose of x.)

4. If H is an $n \times n$ complex positive definite matrix (§6.3.2), then the function defined by $\langle x, y\rangle = y^*Hx$ is an inner product on $\mathcal{C}^n$. (y^* is the conjugate-transpose of y.)

5. The function $\langle f, g\rangle = \int_a^b f(x)g(x)\,dx$ is an inner product on the vector space $C[a, b]$ of continuous real-valued functions on the interval $[a, b]$.

6. The inner product $\langle\cdot,\cdot\rangle$ on an inner product space V is an inner product on any subspace W of V.

7. If W is a subspace of an inner product space V, then the orthogonal complement $W^{\perp}$ is a subspace of V and $V = W \oplus W^{\perp}$.

8. The norm function satisfies the following properties for all scalars a and all vectors $v, w \in V$:

- $\|v\| \ge 0$ with equality if and only if $v = 0$;
- $\|av\| = |a| \cdot \|v\|$, where $|a|$ denotes the absolute value of a;
- $|\langle v, w\rangle| \le \|v\| \cdot \|w\|$ (*Cauchy-Schwarz inequality*);
- $\|v + w\| \le \|v\| + \|w\|$ (*triangle inequality*);
- if $v \ne 0$, then $\dfrac{1}{\|v\|}v$ is a unit vector (the *normalization* of v).

9. The distance function on a vector space V satisfies the following properties for all $v, w, z \in V$:

- $d(v, w) \geq 0$ with equality if and only if $v = w$;
- $d(v, w) = d(w, v)$;
- $d(v, z) \leq d(v, w) + d(w, z)$ (*triangle inequality*).

10. For real inner product spaces, two nonzero vectors are orthogonal if and only if the angle between them is $\theta = \frac{\pi}{2}$.

11. An orthogonal set S of nonzero vectors can be converted to an orthonormal set by normalizing each vector in S.

12. An orthogonal set of nonzero vectors is independent. An orthonormal set is independent.

13. If V is an n-dimensional inner product space, any orthonormal set contains at most n vectors, and any orthonormal set of n vectors is a basis for V.

14. Every subspace W of an n-dimensional space V has an orthonormal (orthogonal) basis.

15. *Gram-Schmidt orthogonalization*: From any ordered basis $(w_1, w_2, \ldots, w_m)$ for a subspace W, an orthonormal basis $(u_1, u_2, \ldots, u_m)$ for W can be constructed using Algorithm 1. (Jörgen Gram, 1850–1916; Erhardt Schmidt, 1876–1959)

```
Algorithm 1: Gram-Schmidt orthogonalization process.
  input: an ordered basis $(w_1, w_2, \ldots, w_m)$
  output: an orthonormal basis $(u_1, u_2, \ldots, u_m)$
  $u_1 := \frac{1}{a_1} w_1$, where $a_1 := \|w_1\|$
  for $j := 2$ to $m$
      $a_j := \|w_j - \sum_{i=1}^{j-1} \langle w_j, u_i \rangle u_i\|$
      $u_j := \frac{1}{a_j}\Big(w_j - \sum_{i=1}^{j-1} \langle w_j, u_i \rangle u_i\Big)$
```

16. The standard basis is orthonormal with respect to the standard inner product.

17. If $(u_1, u_2, \ldots, u_m)$ is an orthonormal basis for a subspace W of V and $w \in W$, then $w = \langle w, u_1 \rangle u_1 + \langle w, u_2 \rangle u_2 + \cdots + \langle w, u_m \rangle u_m$.

18. *Projection vector*: Let W be a subspace of a vector space V and let v be a vector in V.

- There is a unique vector $p \in W$ nearest to v; that is, the vector p minimizes $\|v - w\|$ over all $w \in W$. This vector p is called the *projection* of v onto W, written $p = \text{proj}_W(v)$.
- If $(u_1, u_2, \ldots, u_m)$ is any orthonormal basis for W, then the projection of v onto W is given by $\text{proj}_W(v) = \langle v, u_1 \rangle u_1 + \langle v, u_2 \rangle u_2 + \cdots + \langle v, u_m \rangle u_m$.
- The vector $\text{proj}_W(v)$ is the unique vector $w \in W$ such that $v - w$ is orthogonal to every vector in W.

19. *Projection matrix*: If $V = \mathcal{R}^n$ is equipped with the standard inner product and $(u_1, u_2, \ldots, u_m)$ is an orthonormal basis for a subspace W, then the projection of each $x \in \mathcal{R}^n$ onto W is given by $\text{proj}_W(x) = Ax$, where $A = GG^T$ with $G = (u_1, u_2, \ldots, u_m)$ being the $n \times m$ matrix with the u_i as columns.

20. The projection matrix A is symmetric and satisfies $A^2 = A$.

Examples:

Consider the vector space $\mathcal{R}^4$ with the standard inner product $\langle x, y\rangle = x^T y$, and let W be the subspace spanned by the three vectors $w_1 = (1,1,1,1)^T$, $w_2 = (3,1,3,1)^T$, $w_3 = (3,1,1,1)^T$.

1. $\langle w_1, w_2\rangle = 8$ and $\|w_1\| = 2$.

2. The angle θ between w_1 and w_2 satisfies $\cos\theta = \frac{8}{2\sqrt{20}} = \frac{2}{\sqrt{5}}$ (so $\theta \approx 0.4636$ radians).

3. The distance from w_1 to w_2 is $d(w_1, w_2) = \|w_1 - w_2\| = \|(-2, 0, -2, 0)^T\| = 2\sqrt{2}$.

4. The orthogonal complement $W^\perp$ of W is the set of vectors of the form $(0, a, 0, -a)$.

5. The Gram-Schmidt process applied to (w_1, w_2, w_3) yields

$$u_1 = \tfrac{1}{a_1} w_1 = (\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2})^T, \text{where } a_1 = \|w_1\| = 2;$$

$$\begin{aligned} u_2 &= \tfrac{1}{a_2}(w_2 - \langle w_2, u_1\rangle u_1) = \tfrac{1}{a_2}((3,1,3,1)^T - 4(\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2})^T) \\ &= \tfrac{1}{a_2}(1,-1,1,-1)^T = (\tfrac{1}{2}, -\tfrac{1}{2}, \tfrac{1}{2}, -\tfrac{1}{2})^T, \text{where } a_2 = \|(1,-1,1,-1)^T\| = 2; \end{aligned}$$

$$\begin{aligned} u_3 &= \tfrac{1}{a_3}(w_3 - \langle w_3, u_1\rangle u_1 - \langle w_3, u_2\rangle u_2) \\ &= \tfrac{1}{a_3}\left((3,1,1,1)^T - 3(\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2}, \tfrac{1}{2})^T - 1(\tfrac{1}{2}, -\tfrac{1}{2}, \tfrac{1}{2}, -\tfrac{1}{2})^T\right) \\ &= \tfrac{1}{a_3}(1,0,-1,0)^T = (\tfrac{1}{\sqrt{2}}, 0, -\tfrac{1}{\sqrt{2}}, 0)^T, \text{where } a_3 = \|(1,0,-1,0)^T\| = \sqrt{2}. \end{aligned}$$

6. The vector in W that is nearest to $v = (3,6,3,4)^T$ is $p = \text{proj}_W(v) = \langle v, u_1\rangle u_1 + \langle v, u_2\rangle u_2 + \langle v, u_3\rangle u_3 = 8u_1 + (-2)u_2 + 0u_3 = (3,5,3,5)^T$. Further, $v - p = (0,1,0,-1)^T$ is orthogonal to every vector in W; if $u_4 = (0, \frac{1}{\sqrt{2}}, 0, -\frac{1}{\sqrt{2}})^T$ is the normalization of $v - p$ then (u_1, u_2, u_3, u_4) is an orthonormal basis for $\mathcal{R}^4$.

7. The projection of any $x \in \mathcal{R}^4$ onto W is given by $\text{proj}_W(x) = Ax$, where

$$A = GG^T = (u_1, u_2, u_3)(u_1, u_2, u_3)^T = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 1 & 0 \\ 0 & \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}.$$

Thus, if $x = (3,6,3,4)^T$, its projection onto W is computed as $Ax = (3,5,3,5)^T$, consistent with the answer found in Example 6.

6.2 LINEAR TRANSFORMATIONS

Linear transformations are special types of functions that map one vector space to another. They are called "linear" because of their effect on the lines of a vector space, where by a "line" is meant a set of vectors w of the form $w = au + v$ where $u \neq 0$ and v are fixed vectors in the space and a varies over all values in the scalar field. Linear transformations carry lines in one vector space to lines or points in the other.

6.2.1 LINEAR TRANSFORMATIONS, RANGE, AND KERNEL

Definitions:

Let V and W be vector spaces over the same field F. A ***linear transformation*** is a function $T\colon V \to W$ satisfying $T(au + v) = aT(u) + T(v)$ for all $u, v \in V$ and $a \in F$.

The ***range*** R_T of a linear transformation T is $R_T = \{\, T(v) \mid v \in V \,\}$.

The ***kernel*** $\ker T$ of a linear transformation T is $\ker T = \{\, v \in V \mid T(v) = 0 \,\}$.

The ***rank*** of T is the dimension of R_T. (R_T is a subspace of W by Fact 5.)

The ***nullity*** of T is the dimension of $\ker T$. ($\ker T$ is a subspace of V by Fact 5.)

A ***linear operator*** on V is a linear transformation from V to V.

Facts:

1. For any vector spaces V and W over F, the zero function $Z\colon V \to W$ defined by $Z(v) = 0$ for all $v \in V$ is a linear transformation from V to W.

2. For any vector space V over F, the identity function $I\colon V \to V$ defined by $I(v) = v$ for all $v \in V$ is a linear operator on V.

3. The following four statements are equivalent for a function $T\colon V \to W$:

- T is a linear transformation;
- $T(u + v) = T(u) + T(v)$ and $T(au) = aT(u)$ for all $u, v \in V$ and $a \in F$;
- $T(au + bv) = aT(u) + bT(v)$ for all $u, v \in V$ and $a, b \in F$;
- $T(\sum_{i=1}^{t} a_i v_i) = \sum_{i=1}^{t} a_i T(v_i)$ for all finite subsets $\{v_1, v_2, \ldots, v_t\} \subseteq V$ and scalars $a_i \in F$.

4. If $T\colon V \to W$ is a linear transformation, then

- $T(0) = 0$;
- $T(-v) = -T(v)$ for all $v \in V$;
- $T(u - v) = T(u) - T(v)$ for all $u, v \in V$.

5. If $T\colon V \to W$ is a linear transformation, then R_T is a subspace of W and $\ker T$ is a subspace of V.

6. If $T\colon V \to W$ is a linear transformation, then the rank of T plus the nullity of T equals the dimension of its domain: $\dim R_T + \dim(\ker T) = \dim V$.

7. If $T\colon V \to W$ is a linear transformation and if the vectors $\{v_1, v_2, \ldots, v_n\}$ span V, then $\{T(v_1), T(v_2), \ldots, T(v_n)\}$ span R_T.

8. If $T\colon V \to W$ is a linear transformation, then T is completely determined by its action on a basis for V. That is, if $\mathcal{B}$ is a basis for V and f is any function from $\mathcal{B}$ to W, then there exists a unique linear transformation T such that $T(v) = f(v)$ for all $v \in \mathcal{B}$.

9. A linear transformation $T\colon V \to W$ is one-to-one if and only if $\ker T = \{0\}$.

10. A linear transformation $T\colon V \to W$ is onto if and only if for *every* basis $\mathcal{B}$ of V, the set $\{\, T(v) \mid v \in \mathcal{B} \,\}$ spans W.

11. A linear transformation $T\colon V \to W$ is onto if and only if for *some* basis $\mathcal{B}$ of V, the set $\{\, T(v) \mid v \in \mathcal{B} \,\}$ spans W.

12. If $T\colon V \to W$ is a bijective linear transformation, then its inverse $T^{-1}\colon W \to V$ is also a bijective linear transformation.

13. For each fixed $m \times n$ matrix A over F, the function $T\colon F^{n\times 1} \to F^{m\times 1}$ defined by $T(x) = Ax$ is a linear transformation.

14. Every linear transformation $T\colon F^{n\times 1} \to F^{m\times 1}$ has the form $T(x) = Ax$ for some unique $m \times n$ matrix A over F.

15. The range R_T of the linear transformation $T(x) = Ax$ is equal to the column space of A, and $\ker T$ is equal to the null space of A. (See §6.1.2, §6.1.3.)

16. If T is a linear transformation from V to W and if $T(v_0) = w_0 \in R_T$, then the solution set S to the equation $T(v) = w_0$ is $S = \{\, v_0 + u \mid u \in \ker T \,\}$.

Examples:

1. The function $T\colon \mathcal{R}^{2\times 1} \to \mathcal{R}^{2\times 1}$ given by $T\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} x_1 - 3x_2 \\ -2x_1 + 6x_2 \end{pmatrix}$ is a linear transformation. It has the form $T(x) = Ax$, where $A = \begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$. The kernel of T is $\{\, (3a, a)^T \mid a \in \mathcal{R} \,\}$ and the range of T is $\{\, (b, -2b)^T \mid b \in \mathcal{R} \,\}$.

2. For each fixed matrix $A \in F^{n\times n}$, the function $T\colon F^{n\times n} \to F^{n\times n}$ defined by $T(X) = AX - XA$ is a linear transformation whose kernel is the set of matrices commuting with A. Specifically, let $n = 2$, $F = \mathcal{R}$, and $A = \begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$. Then $\dim \mathcal{R}^{2\times 2} = 4$, and by computation $T\left[\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\right] = \begin{pmatrix} 0 & 3 \\ -2 & 0 \end{pmatrix}$, $T\left[\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}\right] = \begin{pmatrix} 2 & -5 \\ 0 & -2 \end{pmatrix}$. Thus, $\dim R_T \geq 2$. Since both the identity matrix I and A itself are in $\ker T$, $\dim(\ker T) \geq 2$. By Fact 6, it follows that $\dim R_T = 2$ and $\dim(\ker T) = 2$. Therefore (I, A) forms a basis for $\ker T$, and the matrices $\begin{pmatrix} 0 & 3 \\ -2 & 0 \end{pmatrix}$ and $\begin{pmatrix} 2 & -5 \\ 0 & -2 \end{pmatrix}$ are a basis for R_T. From Fact 16, the solutions to $T(x) = \begin{pmatrix} 0 & 3 \\ -2 & 0 \end{pmatrix}$ are precisely the set of matrices of the form $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + a\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + b\begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$ with $a, b \in \mathcal{R}$.

3. The function $E(x_1, x_2, x_3, x_4) = (x_1, x_2, x_3, x_4, x_1 + x_3 + x_4, x_1 + x_2 + x_4, x_1 + x_2 + x_3)$, where $x_i \in \mathcal{Z}_2$, is a linear transformation important in coding theory. It represents an encoding of 4-bit binary vectors into 7-bit binary vectors ("codewords") before being sent over a noisy channel (§14.2). The kernel of the transformation consists of only the zero vector $0 = (0, 0, 0, 0)$, and so the transformation is one-to-one. The collection of codewords (that is, the range of E), is a 16-member, 4-dimensional subspace of $\mathcal{Z}_2^7$ having the special property that any two of its distinct members differ in at least three components. This means that if, during transmission of a codeword, an error is made in any single one of its components, then the error can be detected and corrected as there will be a unique codeword that differs from the received vector in a single component.

4. Continuing with Example 3, the linear transformation $D(z_1, z_2, z_3, z_4, z_5, z_6, z_7) = (z_1 + z_3 + z_4 + z_5, z_1 + z_2 + z_4 + z_6, z_1 + z_2 + z_3 + z_7)$ is used in decoding the (binary) received vector z. This transformation has the special property that its kernel is precisely the set of codewords defined in Example 3. Thus, if $D(z) \neq 0$, then a transmission error has been made.

5. For $\mathcal{C}$ as a vector space over $\mathcal{R}$ and any $z_0 \in \mathcal{C}$, the function $T\colon \mathcal{C} \to \mathcal{C}$ defined by $T(z) = z_0 z$ is a linear operator; in particular, if $z_0 = \cos\theta + i\sin\theta$, then T is a *rotation* by the angle θ. ($T(z)$ is also a linear operator on $\mathcal{C}$ as a vector space over itself.)

6. For any fixed real-valued continuous function g on the interval $[a,b]$, the function T from the space $C[a,b]$ of continuous functions on $[a,b]$ to the space $D[a,b]$ of continuously differentiable functions on $[a,b]$ given by $T(f)(x) = \int_a^x g(t)f(t)dt$ is a linear transformation.

7. For the vector space V of functions $p\colon \mathcal{R} \to \mathcal{R}$ with continuous derivatives of all orders, the mapping $T\colon V \to V$ defined by $T(p) = p'' - 3p' + 2p$ (where p' and p'' are the first and second derivatives of p) is a linear transformation. Its kernel is the solution set to the homogeneous differential equation $p'' - 3p' + 2p = 0$: namely, $p(x) = Ae^x + Be^{2x}$, where $A, B \in \mathcal{R}$. Since $T(x^2) = 2-6x+2x^2$, the set of all solutions to $T(p) = 2-6x+2x^2$ is $x^2 + Ae^x + Be^{2x}$ (by Fact 16).

8. If v_0 is a fixed vector in a real inner product space V, then $T\colon V \to \mathcal{R}$ given by $T(v) = \langle v, v_0\rangle$ is a linear transformation.

9. For W a subspace of the inner product space V, the projection proj_W of V onto W is a linear transformation. (See §6.1.4.)

6.2.2 VECTOR SPACES OF LINEAR TRANSFORMATIONS

Definitions:

If S and T are linear transformations from V to W, the ***sum*** (***addition***) of S and T is the function $S+T$ defined by $(S+T)(v) = S(v) + T(v)$ for all $v \in V$.

If T is a linear transformation from V to W, the ***scalar product*** (***scalar multiplication***) of $a \in F$ by T is the function aT defined by $(aT)(v) = aT(v)$ for all $v \in V$.

If $T\colon V \to W$ and $S\colon W \to U$ are linear transformations, then the ***product*** (***multiplication***, ***composition***) of S and T is the function $S \circ T$ defined by $(S \circ T)(v) = S(T(v))$.

Note: Some writers use the notation vT to denote the image of v under the transformation T, in which case $T \circ S$ is used instead of $S \circ T$ to denote the product; that is, $v(T \circ S) = (vT)S$.

Facts:

1. The sum of two linear transformations from V to W is a linear transformation from V to W.

2. The product of a scalar and a linear transformation is a linear transformation.

3. If $T\colon V \to W$ and $S\colon W \to U$ are linear transformations, then their product $S \circ T$ is a linear transformation from V to U.

4. The set of linear transformations from V to W with the operations of addition and scalar multiplication forms a vector space over F. This vector space is denoted $L(V,W)$.

5. The set $L(V,V)$ of linear operators on V with the operations of addition, scalar multiplication, and multiplication forms an *algebra* with identity over F. Namely, $L(V,V)$ is a vector space over F and is a ring with identity under the addition and multiplication operations. In addition, $a(S \circ T) = (aS) \circ T = S \circ (aT)$ holds for all scalars $a \in F$ and all $S, T \in L(V, V)$. The identity mapping is the multiplicative identity of the algebra.

6. If $\dim V = n$ and $\dim W = m$, then $\dim L(V, W) = nm$.

Examples:

1. Consider $L(F^{n\times 1}, F^{m\times 1})$. If T and S are in $L(F^{n\times 1}, F^{m\times 1})$, then $T(x) = Ax$ and $S(x) = Bx$ for unique $m \times n$ matrices A and B over F. Then $(T + S)(x) = (A + B)x$, $(aT)(x) = aAx$, and in case $m = n$, $(T \circ S)(x) = ABx$.

2. Let $V = C[a, b]$ be the space of real-valued continuous functions on the interval $[a, b]$, and let T and S be linear operators defined by $T(f)(x) = \int_a^x e^{-t} f(t)\, dt$ and $S(f)(x) = \int_a^x e^t f(t)\, dt$. Then $(T+S)(f)(x) = \int_a^x (e^{-t} + e^t) f(t)\, dt$, $(cT)(f)(x) = \int_a^x ce^{-t} f(t)\, dt$, and $(T \circ S)(f)(x) = \int_a^x \int_a^t e^{s-t} f(s)\, ds\, dt$.

3. Let V be the real vector space of all functions $p\colon \mathcal{R} \to \mathcal{R}$ with continuous derivatives of all orders, and let D be the derivative function. Then $D\colon V \to V$ is a linear operator on V and so is a function such as $T = D^2 - 3D + 2I$ where $D^2 = D \circ D$ and I is the identity operator on V. The action of T on $p \in V$ is given by $T(p) = p'' - 3p' + 2p$.

6.2.3 MATRICES OF LINEAR TRANSFORMATIONS

Definitions:

If $T\colon V \to W$ is a linear transformation where $\dim V = n$, $\dim W = m$, and if $\mathcal{B} = (v_1, v_2, \ldots, v_n)$ and $\mathcal{B}' = (v_1', v_2', \ldots, v_m')$ are ordered bases for V and W, respectively, then the ***matrix of T with respect to $\mathcal{B}$ and $\mathcal{B}'$*** is the $m \times n$ matrix $[T]_{\mathcal{B},\mathcal{B}'}$ whose jth column is $[T(v_j)]_{\mathcal{B}'}$, the coordinate vector (§6.1.3) of $T(v_j)$ with respect to $\mathcal{B}'$.

If $T\colon V \to V$ is a linear operator on V, then the ***matrix of T with respect to $\mathcal{B}$*** is the $n \times n$ matrix $[T]_{\mathcal{B},\mathcal{B}}$ denoted simply as $[T]_{\mathcal{B}}$.

Facts:

Assume that T and S are linear transformations from V to W, $\mathcal{B}$ and $\mathcal{B}'$ are respective bases for V and W, and A and B are the matrices defined by $A = [T]_{\mathcal{B},\mathcal{B}'}$ and $B = [S]_{\mathcal{B},\mathcal{B}'}$.

1. $[T(v)]_{\mathcal{B}'} = [T]_{\mathcal{B},\mathcal{B}'}[v]_{\mathcal{B}}$ for all $v \in V$; that is, if $y = [T(v)]_{\mathcal{B}'}$ and $x = [v]_{\mathcal{B}}$, then $y = Ax$.

2. $\ker T = \{\, x_1v_1 + x_2v_2 + \cdots + x_nv_n \mid (x_1, x_2, \ldots, x_n)^T \in NS(A) \,\}$, where $\mathcal{B} = (v_1, v_2, \ldots, v_n)$.

3. T is one-to-one if and only if $NS(A) = \{0\}$.

4. $R_T = \{\, y_1v_1' + y_2v_2' + \cdots + y_mv_m' \mid (y_1, y_2, \ldots, y_m)^T \in CS(A) \,\}$, where $\mathcal{B}' = (v_1', v_2', \ldots, v_m')$.

5. T is onto if and only if $CS(A) = F^{m\times 1}$.

6. T is bijective if and only if $m = n$ and A is invertible. In this case, $[T^{-1}]_{\mathcal{B}',\mathcal{B}} = A^{-1}$.

7. $[T + S]_{\mathcal{B},\mathcal{B}'} = A + B$, $[aT]_{\mathcal{B},\mathcal{B}'} = aA$ for all $a \in F$, and the mapping f from $L(V, W)$ to $F^{m\times n}$ defined by $f(T) = [T]_{\mathcal{B},\mathcal{B}'}$ is an isomorphism.

8. If U is a vector space over F, $\mathcal{B}''$ is a basis for U, and $R\colon W \to U$ is a linear transformation, then $[R \circ T]_{\mathcal{B},\mathcal{B}''} = CA$ where $C = [R]_{\mathcal{B}',\mathcal{B}''}$; that is, $[R \circ T]_{\mathcal{B},\mathcal{B}''} = [R]_{\mathcal{B}',\mathcal{B}''}[T]_{\mathcal{B},\mathcal{B}'}$.

9. The algebra $L(V, V)$ is isomorphic to the matrix algebra $F^{n\times n}$.

10. If $I\colon V \to V$ is the identity mapping, then $[I]_{\mathcal{B},\mathcal{B}} = [I]_{\mathcal{B}}$ equals the identity matrix for any basis $\mathcal{B}$.

11. If A is an $m \times n$ matrix over F with $\mathcal{B}$ and $\mathcal{B}'$ being arbitrary bases for V and W, respectively, then there exists a unique linear transformation $T\colon V \to W$ such that $A = [T]_{\mathcal{B},\mathcal{B}'}$.

12. Linear transformations are used extensively in computer graphics. (See Example 5.) Further information can be found in [PoGe89].

Examples:

1. Consider $T\colon \mathcal{R}^{2\times 1} \to \mathcal{R}^{2\times 1}$ given by $T\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} x_1 - 3x_2 \\ -2x_1 + 6x_2 \end{pmatrix}$ and the bases $\mathcal{B} = (v_1, v_2)$ and $\mathcal{B}' = (v_1', v_2')$, where $v_1 = (1,0)^T$, $v_2 = (0,1)^T$ and $v_1' = (1,1)^T$, $v_2' = (2,1)^T$. Since

$$T(v_1) = (1,-2)^T = (-5)v_1' + 3v_2',$$
$$T(v_2) = (-3,6)^T = 15v_1' + (-9)v_2',$$

it follows that $[T(v_1)]_{\mathcal{B}'} = (-5,3)^T$ and $[T(v_2)]_{\mathcal{B}'} = (15,-9)^T$; hence, the matrix of T relative to $\mathcal{B}$ and $\mathcal{B}'$ is $[T]_{\mathcal{B},\mathcal{B}'} = \begin{pmatrix} -5 & 15 \\ 3 & -9 \end{pmatrix}$. Similarly, $[T]_{\mathcal{B},\mathcal{B}} = [T]_{\mathcal{B}} = \begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$, and $[T]_{\mathcal{B}',\mathcal{B}'} = [T]_{\mathcal{B}'} = \begin{pmatrix} 10 & 5 \\ -6 & -3 \end{pmatrix}$.

2. Consider T of Example 1 where $A = [T]_{\mathcal{B},\mathcal{B}'} = \begin{pmatrix} -5 & 15 \\ 3 & -9 \end{pmatrix}$. Since $NS(A) = \{\,(3a,a)^T \mid a \in \mathcal{R}\,\}$ and $CS(A) = \{\,(-5b,3b)^T \mid b \in \mathcal{R}\,\}$, Fact 2 gives $\ker T = \{\,3av_1 + av_2 = (3a,a)^T \mid a \in \mathcal{R}\,\}$ and Fact 4 gives $R_T = \{\,(-5b)v_1' + 3bv_2' = (b,-2b)^T \mid b \in \mathcal{R}\,\}$. T is not one-to-one since $NS(A) \neq \{0\}$ and is not onto since $CS(A) \neq \mathcal{R}^{2\times 1}$. (Any one of the three matrices found in Example 1 could have been used to determine $\ker T$ and R_T and to reach these same conclusions.)

3. Consider the linear operator on $\mathcal{R}^{2\times 2}$ defined by $T(X) = AX - XA$ where $A = \begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$, and let $\mathcal{B} = (E_{11}, E_{12}, E_{21}, E_{22})$ be the standard basis. (Here, E_{ij} has a 1 in position (i,j) and 0s elsewhere.) Then

$$T(E_{11}) = AE_{11} - E_{11}A = \begin{pmatrix} 0 & 3 \\ -2 & 0 \end{pmatrix} = 0E_{11} + 3E_{12} + (-2)E_{21} + 0E_{22},$$

so $(0,3,-2,0)^T$ is the first column of $[T]_{\mathcal{B}}$. Similar calculations yield

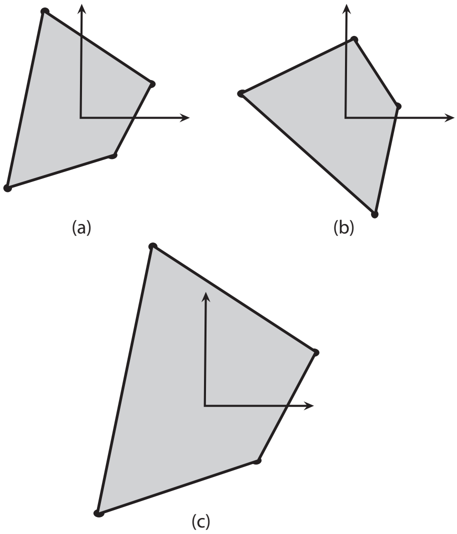
$$[T]_{\mathcal{B}} = \begin{pmatrix} 0 & 2 & -3 & 0 \\ 3 & -5 & 0 & -3 \\ -2 & 0 & 5 & 2 \\ 0 & -2 & 3 & 0 \end{pmatrix}.$$

The null space of this 4×4 matrix is $\{\,(5a+b, 3a, 2a, b)^T \mid a,b \in \mathcal{R}\,\}$, so that those matrices X commuting with A (that is, in $\ker T$) have the form $X = \begin{pmatrix} 5a+b & 3a \\ 2a & b \end{pmatrix}$.

4. Consider $\mathcal{C}$ as a vector space over $\mathcal{R}$ and the rotation operator in Example 5 of §6.2.1; namely, $T(z) = z_0 z$ where $z_0 = \cos\theta + i\sin\theta$. If $\mathcal{B}$ is the standard basis, $\mathcal{B} = (1, i)$, then the matrix of T relative to $\mathcal{B}$ is $[T]_{\mathcal{B}} = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$.

5. *Computer graphics*: The polygon in part (a) of the following figure can be rotated by applying the transformation T in Example 4 to its vertices $(-2,-2)$, $(1,-1)$, $(2,1)$, $(-1,3)$. The matrix of vertex coordinates is

$$X = \begin{pmatrix} -2 & 1 & 2 & -1 \\ -2 & -1 & 1 & 3 \end{pmatrix}.$$



(a)

(b)

(c)

For a rotation of $\frac{\pi}{3}$, the matrix of T is

$$A = \begin{pmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{pmatrix}$$

and

$$AX \approx \begin{pmatrix} 0.732 & 1.366 & 0.134 & -3.098 \\ -2.732 & 0.366 & 2.232 & 0.634 \end{pmatrix},$$

producing the rotated polygon shown in part (b) of the figure. To perform a "zoom in" operation, the original polygon can be rescaled by 50% by applying the transformation $S\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 1.5x \\ 1.5y \end{pmatrix}$. As the matrix for S relative to the standard basis is $D = \begin{pmatrix} 1.5 & 0 \\ 0 & 1.5 \end{pmatrix}$, the vertex coordinates X are transformed into $DX = \begin{pmatrix} -3 & 1.5 & 3 & -1.5 \\ -3 & -1.5 & 1.5 & 4.5 \end{pmatrix}$; see part (c) of the figure. Reflection through the x-axis would involve the transformation $R\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x \\ -y \end{pmatrix}$, represented by the diagonal matrix $C = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. In computer graphics, the vertices of an object are actually given (x, y, z) coordinates and three-dimensional versions of the above transformations can be applied to move and reshape the object as well as render the scene when the user's viewpoint is changed.

6.2.4 CHANGE OF BASIS

Definitions:

Let $\mathcal{B} = (v_1, v_2, \ldots, v_n)$ and $\mathcal{B}' = (v'_1, v'_2, \ldots, v'_n)$ be two ordered bases for V, and let I denote the identity mapping from V to V. The matrix $P = [I]_{\mathcal{B},\mathcal{B}'}$ is the ***transition matrix*** from $\mathcal{B}$ to $\mathcal{B}'$. It is also called the ***change of basis matrix*** from basis $\mathcal{B}$ to basis $\mathcal{B}'$.

If A and B are two $n \times n$ matrices over a field F, then B is ***similar*** to A if there exists an invertible $n \times n$ matrix P over F such that $P^{-1}BP = A$.

Facts:

1. The transition matrix $P = [I]_{\mathcal{B},\mathcal{B}'}$ is invertible; its inverse is $P^{-1} = [I]_{\mathcal{B}',\mathcal{B}}$.

2. If $x = [v]_{\mathcal{B}}$ and $y = [v]_{\mathcal{B}'}$, then $y = Px$ where $P = [I]_{\mathcal{B},\mathcal{B}'}$.

3. When $\mathcal{B} = \mathcal{B}'$, the transition matrix $P = [I]_{\mathcal{B},\mathcal{B}} = [I]_{\mathcal{B}}$ is the $n \times n$ identity matrix.

4. If T is a linear operator on V with A and B the matrices of T relative to bases $\mathcal{B}$ and $\mathcal{B}'$, respectively, then B is similar to A. Specifically, $P^{-1}BP = A$ where $P = [I]_{\mathcal{B},\mathcal{B}'}$.

5. If A and B are similar $n \times n$ matrices, then A and B represent the same linear operator T relative to suitably chosen bases. More specifically, suppose $P^{-1}BP = A$, $\mathcal{B} = (v_1, v_2, \ldots, v_n)$ is any basis for V, and T is the unique linear transformation with $A = [T]_{\mathcal{B}}$. Then $B = [T]_{\mathcal{B}'}$ where $\mathcal{B}' = (v'_1, v'_2, \ldots, v'_n)$ is the basis for V given by $v'_j = \sum_{i=1}^{n} p_{ij}^{-1} v_i$.

Examples:

1. Consider the $\mathcal{R}^{2\times1}$ bases $\mathcal{B} = (v_1, v_2)$ and $\mathcal{B}' = (v'_1, v'_2)$, where $v_1 = (1,0)^T$, $v_2 = (0,1)^T$ and $v'_1 = (1,1)^T$, $v'_2 = (2,1)^T$. Since $v_1 = (-1)v'_1 + v'_2$ and $v_2 = 2v'_1 + (-1)v'_2$, the transition matrix from $\mathcal{B}$ to $\mathcal{B}'$ is $P = [I]_{\mathcal{B},\mathcal{B}'} = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}$, and its inverse $P^{-1} = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix}$ is the transition matrix $[I]_{\mathcal{B}',\mathcal{B}}$. If $v = x_1v_1 + x_2v_2$ where $x_i \in \mathcal{R}$, then by Fact 2, $v = y_1v'_1 + y_2v'_2$ where $y_1 = (-1)x_1 + 2x_2$ and $y_2 = x_1 + (-1)x_2$.

2. Consider $T\colon \mathcal{R}^{2\times1} \to \mathcal{R}^{2\times1}$ given by $T\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} x_1 - 3x_2 \\ -2x_1 + 6x_2 \end{pmatrix}$, and the same bases $\mathcal{B}$ and $\mathcal{B}'$ specified in Example 1. The matrix of T with respect to $\mathcal{B}$ is $[T]_{\mathcal{B}} = A = \begin{pmatrix} 1 & -3 \\ -2 & 6 \end{pmatrix}$ and the matrix of T with respect to $\mathcal{B}'$ is $[T]_{\mathcal{B}'} = B = \begin{pmatrix} 10 & 5 \\ -6 & -3 \end{pmatrix}$. Moreover, A and B are similar; indeed, as Fact 4 shows, $A = P^{-1}BP$ where $P = \begin{pmatrix} -1 & 2 \\ 1 & -1 \end{pmatrix}$ is determined in Example 1.

6.3 MATRIX ALGEBRA

Matrices naturally arise in the analysis of linear systems and in representing discrete structures. This section studies important types of matrices, their properties, and methods for efficient matrix computation.

6.3.1 BASIC CONCEPTS AND SPECIAL MATRICES

Definitions:

The $m \times n$ matrix $A = (a_{ij})$ is a rectangular array of mn real or complex numbers a_{ij}, arranged into m ***rows*** and n ***columns***.

The ***transpose*** of the $m \times n$ matrix $A = (a_{ij})$ is the $n \times m$ matrix $A^T = (b_{ij})$ in which $b_{ij} = a_{ji}$.

The ith row of A, denoted $A(i,:)$, is the array $a_{i1}\ a_{i2}\ \ldots\ a_{in}$. The elements in the ith row can be regarded as a ***row vector*** $(a_{i1}, a_{i2}, \ldots, a_{in})$ in $\mathcal{R}^n$ or $\mathcal{C}^n$. The jth column of A, denoted $A(:,j)$, is the array

$$\begin{matrix} a_{1j} \\ a_{2j} \\ \vdots \\ a_{mj} \end{matrix}$$

which can be identified with the ***column vector*** $(a_{1j}, a_{2j}, \ldots, a_{mj})^T$.

A matrix is ***sparse*** if it has relatively few nonzero entries.

A ***submatrix*** of the matrix A contains the elements occurring in rows $i_1 < i_2 < \cdots < i_k$ and columns $j_1 < j_2 < \cdots < j_r$ of A. A ***principal submatrix*** of the matrix A contains the elements occurring in rows $i_1 < i_2 < \cdots < i_k$ and columns $i_1 < i_2 < \cdots < i_k$ of A. This principal submatrix has ***order*** k and is written $A[i_1, i_2, \ldots, i_k]$.

Two matrices A and B are ***equal*** if they are both $m \times n$ matrices with $a_{ij} = b_{ij}$ for all $i = 1, 2, \ldots, m$ and $j = 1, 2, \ldots, n$.

The ***Hermitian adjoint*** of the $m \times n$ matrix $A = (a_{ij})$ is the $n \times m$ matrix $A^* = (b_{ij})$ in which b_{ij} is the complex conjugate of a_{ji}.

If $m = n$, the matrix $A = (a_{ij})$ is ***square*** with ***diagonal*** elements $a_{11}, a_{22}, \ldots, a_{nn}$. The ***main diagonal*** contains the diagonal elements of A. An ***off-diagonal*** element is any a_{ij} with $i \neq j$. The ***trace*** of A, tr A, is the sum of the diagonal elements of A.

The following table defines special types of square matrices.

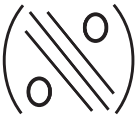
matrix	*definition*
identity	$I_n = (e_{ij})$ where $e_{ij} = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$ ($n \times n$ matrix; each diagonal entry is 1; each off-diagonal entry is 0)
diagonal	$D = (d_{ij})$ where $d_{ij} = 0$ if $i \neq j$ (nonzero entries occur only

matrix	*definition*
	on the main diagonal)
lower triangular	$L = (l_{ij})$ where $l_{ij} = 0$ if $j > i$ (nonzero entries occur only on or below the diagonal)
upper triangular	$U = (u_{ij})$ where $u_{ij} = 0$ if $j < i$ (nonzero entries occur only on or above the diagonal)
unit triangular	triangular matrix with all diagonal entries 1
tridiagonal	$A = (a_{ij})$ where $a_{ij} = 0$ if $\|i - j\| > 1$ (nonzero entries occur only on or immediately above or below the diagonal)
symmetric	real matrix A for which $A = A^T$
skew-symmetric	real matrix A for which $A = -A^T$
Hermitian	complex matrix A for which $A = A^*$
skew-Hermitian	complex matrix A for which $A = -A^*$

Facts:

1. Triangular matrices arise in the solution of systems of linear equations (§6.4).

2. A tridiagonal matrix can be represented as follows, where the diagonal lines represent the (possibly) nonzero entries.



3. Tridiagonal matrices are particular types of sparse matrices. Such matrices arise in discretized versions of continuous problems, the solution of difference equations (§3.3, §3.4.4), and the solution of eigenvalue problems (§6.5).

4. Sparse matrices frequently arise in the solution of large systems of linear equations (§6.4), since in many physical models a given variable typically interacts with relatively few others. Linear systems derived from sparse matrices require less storage space and can be solved more efficiently than those derived from a "dense" matrix.

5. Forming the transpose of a square matrix corresponds to "reflecting" the matrix elements with respect to the main diagonal.

6. Any skew-symmetric matrix A must have $a_{ii} = 0$ for all i.

7. Any Hermitian matrix A must have a_{ii} real for all i.

8. If A is real then $A^* = A^T$.

9. The columns of the identity matrix I_n are the standard basis vectors for $\mathcal{R}^n$ (§6.1.3).

10. Viewed as a linear transformation (§6.2), the identity matrix represents the identity transformation; that is, it leaves all vectors unchanged.

11. Viewed as linear transformations, diagonal matrices with positive diagonal entries leave the directions of the basis vectors unchanged, but alter the relative scale of the basis vectors.

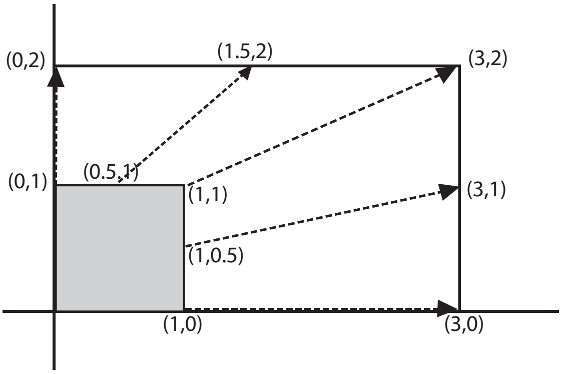
Examples:

1. The 2×2 and 3×3 identity matrices are $I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ and $I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$.

2. The matrix $A = \begin{pmatrix} 6 & 0 & 1 \\ 0 & 2 & 4 \\ 1 & 4 & 3 \end{pmatrix}$ is symmetric.

3. The matrix $A = \begin{pmatrix} 1 & 2-3i \\ 2+3i & -4 \end{pmatrix}$ is Hermitian.

4. A 2×2 diagonal matrix transforms the unit square in $\mathcal{R}^2$ into a rectangle with sides parallel to the coordinate axes. The following figure shows the effect of the diagonal matrix $\begin{pmatrix} 3 & 0 \\ 0 & 2 \end{pmatrix}$ on certain vectors and on the unit square in $\mathcal{R}^2$. The standard basis vectors $\{(1,0)^T, (0,1)^T\}$ have been transformed to $\{(3,0)^T, (0,2)^T\}$.



5. A 3×3 diagonal matrix transforms the unit cube into a rectangular parallelepiped.

6. The standard basis vectors are all eigenvectors of a diagonal matrix with the corresponding diagonal elements as their associated eigenvalues (§6.5).

6.3.2 OPERATIONS OF MATRIX ALGEBRA

Definitions:

The ***scalar product*** (***dot product***) of real vectors $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$ is the number $x \cdot y = \sum_{i=1}^{n} x_i y_i$.

The $n \times n$ matrix A is ***nonsingular*** (***invertible***) if there exists an $n \times n$ matrix A^{-1} such that $AA^{-1} = A^{-1}A = I$. Any such matrix A^{-1} is an ***inverse*** of A.

An ***orthogonal*** matrix is a real square matrix A such that $A^T A = I$.

A ***unitary*** matrix is a complex square matrix A such that $A^* A = I$, where A^* is the Hermitian adjoint of A (§6.3.1).

A ***positive definite*** matrix is a real symmetric (or complex Hermitian) matrix A such that $x^* A x > 0$ for all $x \neq 0$.

The nonnegative ***powers*** of a square matrix A are given by $A^0 = I$, $A^n = AA^{n-1}$. If A is nonsingular then $A^{-n} = (A^{-1})^n$.

The following table defines various operations defined on matrices $A = (a_{ij})$ and $B = (b_{ij})$. (See Facts 1, 2, 5, 6 for restrictions on the sizes of the matrices.)

operation	*definition*
sum $A+B$	$A+B=(c_{ij})$ where $c_{ij}=a_{ij}+b_{ij}$
difference $A-B$	$A-B=(c_{ij})$ where $c_{ij}=a_{ij}-b_{ij}$
scalar multiple αA	$\alpha A=(c_{ij})$ where $c_{ij}=\alpha a_{ij}$
product AB	$AB=(c_{ij})$ where $c_{ij}=\sum_k a_{ik}b_{kj}$

Facts:

1. Matrices of different dimensions cannot be added or subtracted.

2. Square matrices of the same dimension can be multiplied.

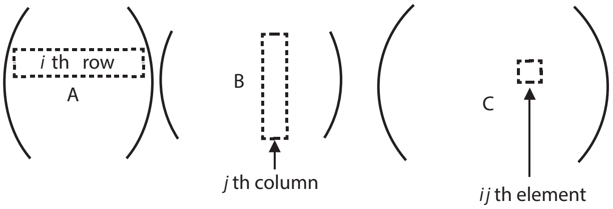
3. Real or complex matrix addition satisfies the following properties:

- *commutative*: $A+B=B+A$;
- *associative*: $A+(B+C)=(A+B)+C$, $A(BC)=(AB)C$;
- *distributive*: $A(B+C)=AB+AC$, $(A+B)C=AC+BC$;
- $\alpha(A+B)=\alpha A+\alpha B$, $\alpha(AB)=(\alpha A)B=A(\alpha B)$ for all scalars α.

4. Matrix multiplication is not, in general, commutative—even when both products are defined. (See Example 3.)

5. The product AB is defined if and only if the number of columns of A equals the number of rows of B. That is, A must be an $m \times n$ matrix and B must be an $n \times p$ matrix.

6. The ijth element of the product $C = AB$ is the scalar product of row i of A and column j of B:



7. Multiplication by identity matrices of the appropriate dimension leaves a matrix unchanged: if A is $m \times n$, then $I_m A = AI_n = A$.

8. Multiplication by diagonal matrices has the effect of scaling the rows or columns of a matrix. Pre-multiplication by a diagonal matrix scales the rows:

$$\begin{pmatrix} d_{11} & 0 & \cdots & 0 \\ 0 & d_{22} & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & d_{nn} \end{pmatrix} \begin{pmatrix} a_{11} & \cdots & a_{1p} \\ a_{21} & \cdots & a_{2p} \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{np} \end{pmatrix} = \begin{pmatrix} d_{11}a_{11} & \cdots & d_{11}a_{1p} \\ d_{22}a_{21} & \cdots & d_{22}a_{2p} \\ \vdots & & \vdots \\ d_{nn}a_{n1} & \cdots & d_{nn}a_{np} \end{pmatrix}.$$

Post-multiplication by a diagonal matrix scales the columns:

$$\begin{pmatrix} a_{11} & \cdots & a_{1n} \\ a_{21} & \cdots & a_{2n} \\ \vdots & & \vdots \\ a_{m1} & \cdots & a_{mn} \end{pmatrix} \begin{pmatrix} d_{11} & 0 & \cdots & 0 \\ 0 & d_{22} & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & d_{nn} \end{pmatrix} = \begin{pmatrix} d_{11}a_{11} & \cdots & d_{nn}a_{1n} \\ d_{11}a_{21} & \cdots & d_{nn}a_{2n} \\ \vdots & & \vdots \\ d_{11}a_{m1} & \cdots & d_{nn}a_{mn} \end{pmatrix}.$$

9. Any Hermitian matrix can be expressed as $A + iB$ where A is symmetric and B is skew-symmetric.

10. The inverse of a (nonsingular) matrix is unique.

11. If A is nonsingular, the solution of the system of linear equations (§6.4) $Ax = b$ is given by (but almost never computed by) $x = A^{-1}b$.

12. The product of nonsingular matrices A and B is nonsingular, with $(AB)^{-1} = B^{-1}A^{-1}$. Conversely, if A and B are square matrices with AB nonsingular, then A and B are nonsingular.

13. For a nonsingular matrix regarded as a linear transformation (§6.2), the inverse matrix represents the inverse transformation.

14. Sums of lower (upper) triangular matrices are lower (upper) triangular.

15. Products of lower (upper) triangular matrices are lower (upper) triangular.

16. A triangular matrix A is nonsingular if and only if $a_{ii} \neq 0$ for all i.

17. If a lower (upper) triangular matrix is nonsingular then its inverse is lower (upper) triangular.

18. *Properties of transpose*:

- $(A^T)^T = A$;
- $(A + B)^T = A^T + B^T$;
- $(AB)^T = B^T A^T$;
- AA^T and $A^T A$ are symmetric;
- if A is nonsingular then so is A^T; moreover $(A^T)^{-1} = (A^{-1})^T$.

19. *Properties of Hermitian adjoint*:

- $(A^*)^* = A$;
- $(A + B)^* = A^* + B^*$;
- $(AB)^* = B^* A^*$;
- AA^* and $A^* A$ are Hermitian;
- if A is nonsingular, then so is A^*; moreover $(A^*)^{-1} = (A^{-1})^*$.

20. If A is orthogonal, then A is nonsingular and $A^{-1} = A^T$.

21. The rows (columns) of an orthogonal matrix are orthonormal with respect to the standard inner product on $\mathcal{R}^n$ (§6.1.4).

22. Products of orthogonal matrices are orthogonal.

23. If A is unitary, then A is nonsingular and $A^{-1} = A^*$.

24. The rows (columns) of a unitary matrix are orthonormal with respect to the standard inner product on $\mathcal{C}^n$ (§6.1.4).

25. Products of unitary matrices are unitary.

26. Positive definite matrices are nonsingular.

27. All eigenvalues (§6.5) of a positive definite matrix are positive.

28. Powers of a positive definite matrix are positive definite.

29. If A is skew-symmetric, then $I + A$ is positive definite.

30. If A is nonsingular, then A^TA is positive definite.

Examples:

1. Let $A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}$ and $B = \begin{pmatrix} 7 & 8 & 9 \\ 0 & 1 & 2 \end{pmatrix}$. Then $A + B = \begin{pmatrix} 8 & 10 & 12 \\ 4 & 6 & 8 \end{pmatrix}$ and $A - B = \begin{pmatrix} -6 & -6 & -6 \\ 4 & 4 & 4 \end{pmatrix}$.

2. The scalar product of the vectors $a = (1, 0, -1)$ and $b = (4, 3, 2)$ is $a \cdot b = (1)(4) + (0)(3) + (-1)(2) = 2$.

3. Let $A = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, $B = \begin{pmatrix} 2 & 3 \\ 4 & 1 \end{pmatrix}$, and $C = \begin{pmatrix} 1 & 1 & 2 \\ 0 & 2 & 3 \end{pmatrix}$. Then AB and BA are both defined with $AB = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 2 & 3 \\ 4 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 6 & 4 \end{pmatrix}$, whereas $BA = \begin{pmatrix} 2 & 3 \\ 4 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 5 & 3 \\ 5 & 1 \end{pmatrix}$. Also, AC is defined but CA is not defined.

4. The matrices A, B of Example 1 cannot be multiplied since A has 3 columns and B has 2 rows; see Fact 5. However, all the products A^TB, AB^T, B^TA, BA^T exist: $A^TB = \begin{pmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{pmatrix} \begin{pmatrix} 7 & 8 & 9 \\ 0 & 1 & 2 \end{pmatrix} = \begin{pmatrix} 7 & 12 & 17 \\ 14 & 21 & 28 \\ 21 & 30 & 39 \end{pmatrix}$, $AB^T = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} \begin{pmatrix} 7 & 0 \\ 8 & 1 \\ 9 & 2 \end{pmatrix} = \begin{pmatrix} 50 & 8 \\ 122 & 17 \end{pmatrix}$, $B^TA = \begin{pmatrix} 7 & 14 & 21 \\ 12 & 21 & 30 \\ 17 & 28 & 39 \end{pmatrix}$, $BA^T = \begin{pmatrix} 50 & 122 \\ 8 & 17 \end{pmatrix}$. Note that $(B^TA)^T = A^TB$, as guaranteed by Fact 18.

5. *Multiplication by a diagonal matrix*: $\begin{pmatrix} 3 & 0 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} = \begin{pmatrix} 3 & 6 & 9 \\ 8 & 10 & 12 \end{pmatrix}$ and $\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} \begin{pmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 6 & 3 \\ 8 & 15 & 6 \end{pmatrix}$.

6. The 2×2 matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is nonsingular if $\Delta = ad - bc \neq 0$; in this case $A^{-1} = \frac{1}{\Delta} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$.

7. The matrix $A = \frac{1}{9} \begin{pmatrix} 4 & 8 & 1 \\ 7 & -4 & 4 \\ -4 & 1 & 8 \end{pmatrix}$ is orthogonal.

8. If $A = \frac{1}{2}\begin{pmatrix} 1 & -i & -1+i \\ i & 1 & 1+i \\ 1+i & -1+i & 0 \end{pmatrix}$ then $A^* = \frac{1}{2}\begin{pmatrix} 1 & -i & 1-i \\ i & 1 & -1-i \\ -1-i & 1-i & 0 \end{pmatrix}$.
Since $A^*A = I$ the matrix A is unitary.

9. Every 2×2 orthogonal matrix Q can be written as $Q = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$ for some real θ. Geometrically, the matrix Q effects a counterclockwise rotation by the angle θ.

10. For the matrix Q in Example 9, $Q^2 = \begin{pmatrix} \cos^2\theta - \sin^2\theta & -2\sin\theta\cos\theta \\ 2\sin\theta\cos\theta & \cos^2\theta - \sin^2\theta \end{pmatrix}$. Since this must be the same as a rotation by an angle of 2θ, then $Q^2 = \begin{pmatrix} \cos 2\theta & -\sin 2\theta \\ \sin 2\theta & \cos 2\theta \end{pmatrix}$. Equating these two expressions for Q^2 gives the double angle formulas of trigonometry.

11. The matrix $\begin{pmatrix} 4 & 2i & -3+i \\ -2i & -8 & 6+3i \\ -3-i & 6-3i & 5 \end{pmatrix}$ is Hermitian. It can be written (see Fact 9) as $A + Bi = \begin{pmatrix} 4 & 0 & -3 \\ 0 & -8 & 6 \\ -3 & 6 & 5 \end{pmatrix} + \begin{pmatrix} 0 & 2i & i \\ -2i & 0 & 3i \\ -i & -3i & 0 \end{pmatrix}$ with A symmetric and B skew-symmetric.

6.3.3 FAST MULTIPLICATION OF MATRICES

A variety of methods have been devised to multiply matrices more efficiently than by simply using the definition in §6.3.2. This section presents alternative methods for carrying out matrix multiplication.

Definitions:

The ***shift left operation*** $\mathrm{shL}(A(i,:),k)$ rotates elements of row i in matrix A exactly k places to the left, where data shifted off the left side of the matrix are wrapped around to the right side.

The ***shift up operation*** $\mathrm{shU}(B(:,j),k)$ rotates elements of column j in matrix B exactly k places up, where data shifted off the top of the matrix are wrapped around to the bottom.

These operations can also be applied simultaneously to every row of A or every column of B, denoted $\mathrm{shL}(A,k)$ and $\mathrm{shU}(B,k)$ respectively.

Facts:

1. The basic definition given in §6.3.2 can be used to multiply the $m \times n$ matrix A and the $n \times p$ matrix B. The associated algorithm (Algorithm 1) requires $O(mnp)$ operations (additions and multiplications of individual elements).

Algorithm 1: **Basic matrix multiplication.**

```
input: $m \times n$ matrix $A$, $n \times p$ matrix $B$
```

```
output: $m \times p$ matrix $C = AB$
for $i := 1$ to $m$
  for $j := 1$ to $p$
    $C(i,j) := 0$
    for $k := 1$ to $n$
      $C(i,j) := C(i,j) + A(i,k)B(k,j)$
```

2. *Matrix multiplication in scalar product form*: Algorithm 1 can be rewritten in terms of the scalar product operation, giving Algorithm 2.

```
Algorithm 2: Scalar product form of matrix multiplication.
input: $m \times n$ matrix $A$, $n \times p$ matrix $B$
output: $m \times p$ matrix $C = AB$
for $i := 1$ to $m$
  for $j := 1$ to $p$
    $C(i,j) := A(i,:) \cdot B(:,j)$
```

3. Algorithm 2 is well suited for fast multiplication on computers designed for efficient scalar product operations. It requires $O(mp)$ scalar products.

4. *Matrix multiplication in linear combination form*: Algorithm 3 carries out matrix multiplication by taking a linear combination of columns of A to obtain each column of the product.

```
Algorithm 3: Column linear combination form of matrix multiplication.
input: $m \times n$ matrix $A$, $n \times p$ matrix $B$
output: $m \times p$ matrix $C = AB$
for $j := 1$ to $p$
  $C(:,j) := 0$
  for $k := 1$ to $n$
    $C(:,j) := C(:,j) + B(k,j)A(:,k)$
```

5. The inner loop of Algorithm 3 performs a "vector + (scalar × vector)" operation, well suited to a vector computer using efficiently pipelined arithmetic processing.

6. Algorithm 3 is often used for fast general matrix multiplication on vector machines since it is based on a natural vector operation. If these vector operations can be performed on all elements simultaneously, then $O(np)$ vector operations are needed.

7. Access to matrix elements in Algorithm 3 is by column. There are other rearrangements of the algorithm which access matrix information by row.

8. *Fast multiplication on array processors*: Algorithm 4 multiplies two $n \times n$ (or smaller dimension) matrices on a computer with an $n \times n$ array of processors. It uses various shift operations on the arrays and the array-multiplication operation $(*)$ of elementwise multiplication.

```
Algorithm 4: Array processor matrix multiplication.
  input: $n \times n$ matrices $A, B$
  output: $n \times n$ matrix $C = AB$
  {Preshift the matrix arrays}
  for $i := 1$ to $n$
    shL$(A(i,:), i-1)$      {Shift $i$th row $i-1$ places left}
    shU$(B(:,i), i-1)$      {Shift $i$th column $i-1$ places up}
  $C := 0$      {Initialize product array}
  for $k := 1$ to $n$
    $C := C + A * B$
    shL$(A, 1)$
    shU$(B, 1)$
```

9. At each step Algorithm 4 shifts A one place to the left and shifts B one place up so that components of the array product are correct new terms for the corresponding elements of $C = AB$. Each matrix is preshifted so the first step complies with this requirement.

10. Two $n \times n$ matrices can be multiplied in $O(n)$ time using Algorithm 4 on an array processor.

11. *Strassen's algorithm*: Algorithm 5 recursively carries out matrix multiplication for $n \times n$ matrices A and B where $n = 2^k$. The basis of Strassen's algorithm is partitioning the two factors into square blocks with dimension half that of the original matrices.

```
Algorithm 5: Strassen's algorithm for $2^k \times 2^k$ matrices.
  procedure Strassen$(A, B)$
  input: $2^k \times 2^k$ matrices $A, B$
  output: $2^k \times 2^k$ matrix $C = AB$
  if $k = 1$ then use Algorithm 6
  else
    partition $A$, $B$ into four $2^{k-1} \times 2^{k-1}$ blocks $A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}$, $B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}$
    $P := Strassen((A_{11} + A_{22}), (B_{11} + B_{22}))$
    $Q := Strassen((A_{21} + A_{22}), B_{11})$;  $R := Strassen(A_{11}, (B_{12} - B_{22}))$
    $S := Strassen(A_{22}, (B_{21} - B_{11}))$;  $T := Strassen((A_{11} + A_{12}), B_{22})$
    $U := Strassen((A_{21} - A_{11}), (B_{11} + B_{12}))$
    $V := Strassen((A_{12} - A_{22}), (B_{21} + B_{22}))$
    $C_{11} := P + S - T + V$;  $C_{12} := R + T$;  $C_{21} := Q + S$;  $C_{22} := P - Q + R + U$
  $C := \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}$
```

12. Strassen's algorithm ultimately requires the fast multiplication of 2 × 2 matrices (Algorithm 6).

```
Algorithm 6: Strassen's algorithm for $2 \times 2$ matrices.
  input: $2 \times 2$ matrices $A, B$
  output: $2 \times 2$ matrix $C = AB$
  $p := (a_{11} + a_{22})(b_{11} + b_{22})$; $q := (a_{21} + a_{22})b_{11}$; $r := a_{11}(b_{12} - b_{22})$
  $s := a_{22}(b_{21} - b_{11})$; $t := (a_{11} + a_{12})b_{22}$; $u := (a_{21} - a_{11})(b_{11} + b_{12})$
  $v := (a_{12} - a_{22})(b_{21} + b_{22})$
  $c_{11} := p + s - t + v$; $c_{12} := r + t$; $c_{21} := q + s$; $c_{22} := p - q + r + u$
```

13. Algorithm 6 multiplies two 2×2 matrices using only 7 multiplications and 18 additions instead of the normal 8 multiplications and 4 additions. For most modern computers saving one multiplication at the cost of 14 extra additions would not represent a gain.

14. Strassen's algorithm can be extended to $n \times n$ matrices where n is not a power of 2. The general algorithm requires $O(n^{\log_2 7}) \approx O(n^{2.807})$ multiplications. Details of this algorithm and its efficiency can be found in [GoVL13].

Examples:

1. This example illustrates Algorithm 4 for 4×4 array matrix multiplication. The preshift and the first array multiplication yield the arrays

$$\begin{array}{cccc} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{22} & a_{23} & a_{24} & a_{21} \\ a_{33} & a_{34} & a_{31} & a_{32} \\ a_{44} & a_{41} & a_{42} & a_{43} \end{array} \qquad \begin{array}{cccc} b_{11} & b_{22} & b_{33} & b_{44} \\ b_{21} & b_{32} & b_{43} & b_{14} \\ b_{31} & b_{42} & b_{13} & b_{24} \\ b_{41} & b_{12} & b_{23} & b_{34} \end{array} \qquad \begin{array}{cccc} a_{11}b_{11} & a_{12}b_{22} & a_{13}b_{33} & a_{14}b_{44} \\ a_{22}b_{21} & a_{23}b_{32} & a_{24}b_{43} & a_{21}b_{14} \\ a_{33}b_{31} & a_{34}b_{42} & a_{31}b_{13} & a_{32}b_{24} \\ a_{44}b_{41} & a_{41}b_{12} & a_{42}b_{23} & a_{43}b_{34} \end{array}$$

The next shifts and multiply-accumulate operation produce

$$\begin{array}{cccc} a_{12} & a_{13} & a_{14} & a_{11} \\ a_{23} & a_{24} & a_{21} & a_{22} \\ a_{34} & a_{31} & a_{32} & a_{33} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{array} \qquad \begin{array}{cccc} b_{21} & b_{32} & b_{43} & b_{14} \\ b_{31} & b_{42} & b_{13} & b_{24} \\ b_{41} & b_{12} & b_{23} & b_{34} \\ b_{11} & b_{22} & b_{33} & b_{44} \end{array}$$

$$\begin{array}{cccc} a_{11}b_{11} + a_{12}b_{21} & a_{12}b_{22} + a_{13}b_{32} & a_{13}b_{33} + a_{14}b_{43} & a_{14}b_{44} + a_{11}b_{14} \\ a_{22}b_{21} + a_{23}b_{31} & a_{23}b_{32} + a_{24}b_{42} & a_{24}b_{43} + a_{21}b_{13} & a_{21}b_{14} + a_{22}b_{24} \\ a_{33}b_{31} + a_{34}b_{41} & a_{34}b_{42} + a_{31}b_{12} & a_{31}b_{13} + a_{32}b_{23} & a_{32}b_{24} + a_{33}b_{34} \\ a_{44}b_{41} + a_{41}b_{11} & a_{41}b_{12} + a_{42}b_{22} & a_{42}b_{23} + a_{43}b_{33} & a_{43}b_{34} + a_{44}b_{44} \end{array}$$

At subsequent stages the remaining terms get added in to the appropriate elements of the product matrix. The total cost of matrix multiplication is therefore reduced to n parallel multiply-accumulate operations plus some communication costs, which for a typical distributed memory array processor are generally small.

2. Algorithm 6 is illustrated using the matrices $A = \begin{pmatrix} 3 & 4 \\ -1 & 2 \end{pmatrix}$, $B = \begin{pmatrix} 7 & 3 \\ 1 & -3 \end{pmatrix}$. Then

$$\begin{array}{llll} p = 5 \cdot 4 = 20, & q = 1 \cdot 7 = 7, & r = 3 \cdot 6 = 18, & s = 3 \cdot (-6) = -12, \\ t = 7 \cdot (-3) = -21, & u = (-4) \cdot 10 = -40, & v = 2 \cdot (-2) = -4, & \end{array}$$

giving the following elements of $C = AB$: $c_{11} = 20 - 12 + 21 - 4 = 25$, $c_{12} = 18 - 21 = -3$, $c_{21} = 7 - 12 = -5$, $c_{22} = 20 - 7 + 18 - 40 = -9$.

6.3.4 DETERMINANTS

Definitions:

For an $n \times n$ matrix A with $n > 1$, A_{ij} denotes the $(n-1) \times (n-1)$ matrix obtained by deleting row i and column j from A.

The ***determinant*** $\det A$ of an $n \times n$ matrix A can be defined recursively:

- if $A = (a)$ is a 1×1 matrix, then $\det A = a$;
- if $n > 1$, then $\det A = \sum_{j=1}^{n} (-1)^{j+1} a_{1j} \det A_{1j}$.

A ***minor*** of a matrix is the determinant of a square submatrix of the given matrix. A ***principal minor*** is the determinant of a principal submatrix.

Notation: The determinant of $A = (a_{ij})$ is commonly written using vertical bars:

$$\det A = |A| = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}.$$

Facts:

1. *Laplace expansion*: For any r,

$$\det A = \sum_{j=1}^{n} (-1)^{r+j} a_{rj} \det A_{rj} = \sum_{i=1}^{n} (-1)^{i+r} a_{ir} \det A_{ir}.$$

2. If $A = (a_{ij})$ is $n \times n$, then $\det A = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma)\, a_{1\sigma(1)} a_{2\sigma(2)} \ldots a_{n\sigma(n)}$. Here S_n is the set of all permutations on $\{1, 2, \ldots, n\}$, and $\operatorname{sgn}(\sigma)$ equals 1 if σ is even and -1 if σ is odd (§5.3.1).

3. $\det \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc.$

4. $\det \begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix} = \begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix} = aei + bfg + cdh - afh - bdi - ceg.$

5. $\det AB = \det A \det B = \det BA$ for all $n \times n$ matrices A, B.

6. $\det A^T = \det A$ for all $n \times n$ matrices A.

7. $\det \alpha A = \alpha^n \det A$ for all $n \times n$ matrices A and all scalars α.

8. $\det I = 1$.

9. If A has two identical rows (or two identical columns), then $\det A = 0$.

10. Interchanging two rows (or two columns) of a matrix changes the sign of the determinant.

11. Multiplying one row (or column) of a matrix by a scalar multiplies its determinant by that same scalar.

12. Adding a multiple of one row (column) to another row (column) leaves the value of the determinant unchanged.

13. If $D = (d_{ij})$ is an $n \times n$ diagonal matrix, then $\det D = d_{11}d_{22}\dots d_{nn}$.

14. If $T = (t_{ij})$ is an $n \times n$ triangular matrix, then $\det T = t_{11}t_{22}\dots t_{nn}$.

15. If A and D are square matrices, then $\det \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} = \det A \, \det D = \det \begin{pmatrix} A & 0 \\ C & D \end{pmatrix}$.

16. A is nonsingular if and only if $\det A \neq 0$.

17. If A is nonsingular then $\det(A^{-1}) = \dfrac{1}{\det A}$.

18. If A and D are nonsingular, then $\det \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det A \, \det(D - CA^{-1}B) = \det D \, \det(A - BD^{-1}C)$.

19. The determinant of a Hermitian matrix (§6.3.1) is real.

20. The determinant of a skew-symmetric matrix (§6.3.1) of odd size is zero.

21. The determinant of an orthogonal matrix (§6.3.2) is ±1.

22. The $n \times n$ symmetric (or Hermitian) matrix A is positive definite if and only if all its leading principal submatrices $A[1], A[1,2], \dots, A[1,2,\dots,n]$ have a positive determinant.

23. The $n \times n$ *Vandermonde matrix*

$$\begin{pmatrix} 1 & x_1 & \dots & x_1^{n-1} \\ 1 & x_2 & \dots & x_2^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & x_n & \dots & x_n^{n-1} \end{pmatrix}$$

has determinant $\prod_{i<j}(x_j - x_i)$.

24. If the $n \times n$ matrix $A = (a_{ij})$ has diagonal elements $a_{ii} = x$ and off-diagonal elements $a_{ij} = y$, then $\det A = (x-y)^{n-1}(x - y + ny)$.

25. The equation of the straight line through points (a_1, b_1) and (a_2, b_2) is given by

$$\begin{vmatrix} x & y & 1 \\ a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \end{vmatrix} = 0.$$

26. The equation of the circle through points (a_1, b_1), (a_2, b_2), (a_3, b_3) is given by

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ a_1^2 + b_1^2 & a_1 & b_1 & 1 \\ a_2^2 + b_2^2 & a_2 & b_2 & 1 \\ a_3^2 + b_3^2 & a_3 & b_3 & 1 \end{vmatrix} = 0.$$

27. If the three points (a_1, b_1), (a_2, b_2), (a_3, b_3) are listed in counterclockwise order, then the area of the triangle they form is given by

$$\frac{1}{2} \begin{vmatrix} a_1 & b_1 & 1 \\ a_2 & b_2 & 1 \\ a_3 & b_3 & 1 \end{vmatrix}.$$

28. The parallelepiped $P = \{\, \alpha_1 a_1 + \alpha_2 a_2 + \dots + \alpha_n a_n \mid 0 \leq \alpha_i \leq 1 \,\}$ spanned by the vectors $a_1, a_2, \dots, a_n$ has volume $|\det A\,|$, where A has columns $a_1, a_2, \dots, a_n$.

29. *Computation*: The determinant is (almost) never computed from the definition or from Fact 2. Instead it is calculated using Facts 12 and 14. (See Example 1.)

Examples:

1. Determinants can be calculated by using row operations to create a triangular matrix, and then applying Fact 14:

$$\det\begin{pmatrix}-1 & 2 & 1\\ 0 & 5 & 2\\ 3 & 4 & 3\end{pmatrix} = \det\begin{pmatrix}-1 & 2 & 1\\ 0 & 5 & 2\\ 0 & 10 & 6\end{pmatrix} = \det\begin{pmatrix}-1 & 2 & 1\\ 0 & 5 & 2\\ 0 & 0 & 2\end{pmatrix} = -10.$$

Here the second matrix is obtained from the first by adding 3 times row 1 to row 3; the third matrix is obtained from the second by adding -2 times row 2 to row 3.

2. Determinants can be calculated by using row and column interchanges to obtain a form with exploitable zeros:

$$\det\begin{pmatrix}4 & 5 & 1 & 6\\ 0 & 6 & 0 & 3\\ 0 & 5 & 0 & 2\\ 3 & 3 & 2 & 4\end{pmatrix} = -\det\begin{pmatrix}4 & 1 & 5 & 6\\ 0 & 0 & 6 & 3\\ 0 & 0 & 5 & 2\\ 3 & 2 & 3 & 4\end{pmatrix} = \det\begin{pmatrix}4 & 1 & 5 & 6\\ 3 & 2 & 3 & 4\\ 0 & 0 & 5 & 2\\ 0 & 0 & 6 & 3\end{pmatrix}.$$

Here the second matrix is obtained from the first by interchanging columns 2 and 3; the third matrix is obtained from the second by interchanging rows 2 and 4. The third matrix has block triangular form, with diagonal blocks $A = \begin{pmatrix}4 & 1\\ 3 & 2\end{pmatrix}$ and $D = \begin{pmatrix}5 & 2\\ 6 & 3\end{pmatrix}$. By Fact 15, the original determinant equals $\det A \det D = 5 \cdot 3 = 15$.

3. The symmetric matrix $A = \begin{pmatrix}3 & 1 & 0\\ 1 & 5 & 3\\ 0 & 3 & 4\end{pmatrix}$ is positive definite, since its leading principal minors (Fact 22) are positive: $\det(3) = 3 > 0$, $\det\begin{pmatrix}3 & 1\\ 1 & 5\end{pmatrix} = 14 > 0$, and (by Fact 1) $\det A = 3\det\begin{pmatrix}5 & 3\\ 3 & 4\end{pmatrix} - \det\begin{pmatrix}1 & 3\\ 0 & 4\end{pmatrix} = 3 \cdot 11 - 4 = 29 > 0$.

4. The equation of the line through points $(1,3)$ and $(4,5)$ can be found using Fact 25:

$$\begin{vmatrix}x & y & 1\\ 1 & 3 & 1\\ 4 & 5 & 1\end{vmatrix} = \begin{vmatrix}x & y & 1\\ 1 & 3 & 1\\ 0 & -7 & -3\end{vmatrix} = \begin{vmatrix}x & y-\frac{7}{3} & 1\\ 1 & \frac{2}{3} & 1\\ 0 & 0 & -3\end{vmatrix} = (\frac{2}{3}x - y + \frac{7}{3})(-3) = 0,$$

giving $\frac{2}{3}x - y + \frac{7}{3} = 0$ or $y = \frac{2}{3}x + \frac{7}{3}$.

5. By Fact 27, the area of the triangle formed by the points $(0,0)$, $(1,3)$, and $(4,5)$ is

$$\frac{1}{2}\begin{vmatrix}0 & 0 & 1\\ 4 & 5 & 1\\ 1 & 3 & 1\end{vmatrix} = \frac{1}{2}\begin{vmatrix}4 & 5\\ 1 & 3\end{vmatrix} = \frac{7}{2}.$$

6. *Cayley's formula*: The determinant of the $(n-1) \times (n-1)$ matrix

$$T_n = \begin{pmatrix}n-1 & -1 & \dots & -1\\ -1 & n-1 & \dots & -1\\ \vdots & \vdots & & \vdots\\ -1 & -1 & \dots & n-1\end{pmatrix}$$

counts the number of spanning trees of a complete graph. (See §9.2.2.) Using Fact 24, $\det T_n = n^{n-2}[n - (n-1)] = n^{n-2}$.

6.3.5 RANK

Definition:

The ***rank*** of an $m \times n$ matrix A, written $\operatorname{rank} A$, is the size of the largest square nonsingular submatrix of A.

Facts:

1. $\operatorname{rank} A = \operatorname{rank} A^T$.

2. The rank of A equals the maximum number of linearly independent rows or linearly independent columns in A.

3. $\operatorname{rank}(A + B) \le \operatorname{rank} A + \operatorname{rank} B$.

4. $\operatorname{rank} AB \le \min\{\operatorname{rank} A, \operatorname{rank} B\}$.

5. If A is nonsingular then $\operatorname{rank} AB = \operatorname{rank} B$ and $\operatorname{rank} CA = \operatorname{rank} C$.

6. $\operatorname{rank} A = \dim CS(A)$, where $CS(A)$ is the column space of A and $\dim V$ denotes the dimension of the vector space V. (See §6.1.3.)

7. $\operatorname{rank} A = \dim RS(A)$, where $RS(A)$ is the row space of A. (See §6.1.3.)

8. An $n \times n$ matrix A is nonsingular if and only if $\operatorname{rank} A = n$.

9. Every matrix of rank r can be written as a sum of r matrices of rank 1.

10. If a and b are nonzero $n \times 1$ vectors, then ab^T is an $n \times n$ matrix of rank 1.

11. The rank of a matrix is not always easy to compute. In the absence of severe roundoff errors, it can be obtained by counting the number of nonzero rows at the end of the Gaussian elimination procedure (§6.4.2).

12. *System of linear equations*: Consider the system $Ax = b$, where A is $m \times n$. Let $A_b = (A : b)$ denote the $m \times (n+1)$ matrix whose $(n+1)$st column is the vector b. Then the system $Ax = b$ has

- a unique solution $\Leftrightarrow$ $\operatorname{rank} A = \operatorname{rank} A_b = n$;
- infinitely many solutions $\Leftrightarrow$ $\operatorname{rank} A = \operatorname{rank} A_b < n$;
- no solution $\Leftrightarrow$ $\operatorname{rank} A < \operatorname{rank} A_b$.

Examples:

1. The matrix $A = \begin{pmatrix} 1 & -1 & 2 \\ 3 & 4 & -1 \\ 5 & 2 & 3 \end{pmatrix}$ is singular since $\det A = 0$. However, the submatrix $A[1,2] = \begin{pmatrix} 1 & -1 \\ 3 & 4 \end{pmatrix}$ has determinant 7 and so is nonsingular, showing that $\operatorname{rank} A = 2$. The matrix A has two linearly independent rows: row 3 = 2 × (row 1) + (row 2). Likewise, it has two linearly independent columns: column 3 = (column 1) − (column 2). This again confirms (by Fact 2) that $\operatorname{rank} A = 2$.

2. Consider the system of equations $Ax = b$, where A is the matrix in Example 1 and $b = (0, 7, 7)^T$. Since rank A = rank $A_b = 2 < 3$, this system has infinitely many solutions x. In fact, the set of solutions is given by $\{\, (1-\alpha, 1+\alpha, \alpha)^T \mid \alpha \in \mathcal{R} \,\}$.

3. The matrix $A = \begin{pmatrix} 1 & x & x^2 \\ x & x^2 & x^3 \\ x^2 & x^3 & x^4 \end{pmatrix}$ can be expressed as the product aa^T where a is the column vector $(1, x, x^2)^T$. By Fact 10, A has rank 1.

6.3.6 IDENTITIES OF MATRIX ALGEBRA

Facts:

1. *Cauchy-Binet formula*: If C is $m \times m$ and $C = AB$ where A is $m \times n$ and B is $n \times m$, then the determinant of C is given by the sum of all products of order m minors of A and the corresponding order m minors of B:

$$\det C = \sum_{1 \le s_1 < s_2 < \cdots < s_m \le n} \begin{vmatrix} a_{1s_1} & a_{1s_2} & \cdots & a_{1s_m} \\ a_{2s_1} & a_{2s_2} & \cdots & a_{2s_m} \\ \vdots & \vdots & & \vdots \\ a_{ms_1} & a_{ms_2} & \cdots & a_{ms_m} \end{vmatrix} \cdot \begin{vmatrix} b_{s_1 1} & b_{s_1 2} & \cdots & b_{s_1 m} \\ b_{s_2 1} & b_{s_2 2} & \cdots & b_{s_2 m} \\ \vdots & \vdots & & \vdots \\ b_{s_m 1} & b_{s_m 2} & \cdots & b_{s_m m} \end{vmatrix}.$$

- If $m = n$ there is only one possible selection; the Cauchy-Binet formula for this case reduces to $\det C = \det A \, \det B$; (see Fact 5, §6.3.4).
- If $m > n$ no possible selections exist (the sum is empty), so $\det C = 0$.

2. *Courant-Fischer minimax identity*: If the eigenvalues (§6.5) of an $n \times n$ Hermitian matrix A are ordered so that $\lambda_1 \ge \lambda_2 \ge \cdots \ge \lambda_n$, then $\lambda_k = \max_{\dim V = k} \min_{0 \ne x \in V} \frac{x^T A x}{x^T x}$ where V is a linear subspace of $\mathcal{C}^n$.

3. *Hadamard's inequality*: This gives an upper bound for the determinant of an $n \times n$ matrix A in terms of the l_2 norms (§6.4.5) of its rows (or columns):

- in terms of rows: $(\det A)^2 \le \prod_{i=1}^n \left(\sum_{j=1}^n |a_{ij}|^2 \right) = \prod_{i=1}^n ||A(i,:)||^2$;
- in terms of columns: $(\det A)^2 \le \prod_{j=1}^n \left(\sum_{i=1}^n |a_{ij}|^2 \right) = \prod_{j=1}^n ||A(:,j)||^2$.

4. *Sherman-Morrison identity*: If A is a nonsingular $n \times n$ matrix and $u, v \in \mathcal{R}^n$, then

$$(A - uv^T)^{-1} = A^{-1} + \frac{1}{1 - v^T A^{-1} u} (A^{-1} u v^T A^{-1}).$$

5. *Woodbury's identity*: If A is nonsingular, then

$$(A - UV^T)^{-1} = A^{-1} + A^{-1} U (I - V^T A^{-1} U)^{-1} V^T A^{-1}.$$

6. Suppose A is a nonsingular $n \times n$ matrix, with S a set of k indices $i_1 < i_2 < \cdots < i_k$ and $\overline{S}$ the set of remaining indices in $\{1, 2, \ldots, n\}$. Then the principal minors of A^{-1} are related to the principal minors of A via

$$\det A^{-1}[S] = \frac{1}{\det A} \det A[\overline{S}].$$

7. *Jacobi's identity*: If the $n \times n$ system of linear differential equations $\dfrac{dx}{dt} = P(t)x$ has the linearly independent family of solutions $X(:,j)(t)$ for $j = 1, 2, \ldots, n$, then the determinant of the (variable) matrix $X(t)$ whose columns are the $X(:,j)(t)$ is given by

$$\det X(t_1) = c \exp\left(\int_{t_0}^{t_1} \operatorname{tr} P(t)\, dt\right),$$

where c is a constant and $\operatorname{tr} P(t) = p_{11}(t) + p_{22}(t) + \cdots + p_{nn}(t)$ is the trace of the matrix $P(t)$.

6.4 LINEAR SYSTEMS

The need to find solutions of linear systems arises in numerous branches of science and engineering (physics, biology, chemistry, structural engineering, electrical engineering, civil engineering) as well as in statistics and applied mathematics. This section discusses various techniques for the efficient solution of such systems, especially important when these systems are large and sparse.

6.4.1 BASIC CONCEPTS

This subsection is concerned with representing and solving a system of m linear equations in n unknowns. Throughout, the focus will be on systems whose data are real numbers. The extension to linear systems with complex data is straightforward.

Definitions:

A ***linear equation*** in unknowns $x_1, x_2, \ldots, x_n$ is an equation of the form $\sum_{j=1}^{n} a_j x_j = b$, where the ***coefficients*** $a_j \in \mathcal{R}$ and the ***right-hand side*** $b \in \mathcal{R}$. A ***solution*** of this equation is any set of values $x_1, x_2, \ldots, x_n$ satisfying the given equation.

A ***system of linear equations*** in unknowns $x_1, x_2, \ldots, x_n$ is a collection of m equations $\sum_{j=1}^{n} a_{ij} x_j = b_i$, $i = 1, 2, \ldots, m$ where all $a_{ij} \in \mathcal{R}$ and all $b_i \in \mathcal{R}$. A ***solution*** of this system is any set of values $x_1, x_2, \ldots, x_n$ satisfying (simultaneously) the m given equations. The ***coefficient matrix*** of this system is the $m \times n$ matrix $A = (a_{ij})$, and the ***augmented matrix*** is the $m \times (n+1)$ matrix $A_b = (A : b)$.

A ***homogeneous*** system has right-hand sides $b_i = 0$ for all $i = 1, 2, \ldots, m$; otherwise the system is ***nonhomogeneous***.

Back substitution is a simple and efficient iterative procedure for solving an upper triangular linear system $Ux = b$, one unknown at a time.

Forward substitution is a simple and efficient iterative procedure for solving a lower triangular linear system $Lx = b$, one unknown at a time.

Facts:

1. A system of m linear equations in the unknowns $x_1, x_2, \ldots, x_n$ can be represented by the linear system $Ax = b$ where A is the $m \times n$ coefficient matrix, $x = (x_1, x_2, \ldots, x_n)^T$ is the column vector of unknowns, and $b = (b_1, b_2, \ldots, b_m)^T$ is the column vector of right-hand sides.

2. Given the linear system $Ax = b$, where A is $m \times n$

- the system has no solution when $\operatorname{rank} A < \operatorname{rank} A_b$;
- the system has a unique solution when $\operatorname{rank} A = \operatorname{rank} A_b = n$;
- the system has infinitely many solutions when $\operatorname{rank} A = \operatorname{rank} A_b < n$; in this case the set of solutions is an affine subspace of dimension $n - \operatorname{rank} A$ (§6.1.3).

3. If the square matrix A is nonsingular (§6.3.2), then $Ax = b$ has the unique solution vector $x = A^{-1}b$.

4. If the square matrix $L = (l_{ij})$ is lower triangular, then $Lx = b$ has a unique solution whenever $l_{ii} \neq 0$ for all i. In this case the solution can be found using *forward substitution* (Algorithm 1).

```
Algorithm 1:  Forward substitution.
  input: $n \times n$ nonsingular matrix $L$, $n \times 1$ vector $b$
  output: $n \times 1$ vector $x = L^{-1}b$
  $x_1 := \frac{b_1}{l_{11}}$
  for $i := 2$ to $n$
      $x_i := \frac{1}{l_{ii}}\Big(b_i - \sum_{j=1}^{i-1} l_{ij}x_j\Big)$
```

5. If the square matrix $U = (u_{ij})$ is upper triangular, then $Ux = b$ has a unique solution whenever $u_{ii} \neq 0$ for all i. In this case the solution can be found using *back substitution* (Algorithm 2).

```
Algorithm 2:  Back substitution.
  input: $n \times n$ nonsingular matrix $U$, $n \times 1$ vector $b$
  output: $n \times 1$ vector $x = U^{-1}b$
  $x_n := \frac{b_n}{u_{nn}}$
  for $i := n-1$ down to $1$
      $x_i := \frac{1}{u_{ii}}\Big(b_i - \sum_{j=i+1}^{n} u_{ij}x_j\Big)$
```

Examples:

1. The system of linear equations

$$\begin{aligned} x_1 + 3x_2 + 4x_3 &= 1 \\ 3x_1 + 5x_2 + 0x_3 &= 7 \end{aligned}$$

corresponds to the linear system $Ax = b$, where $A = \begin{pmatrix} 1 & 3 & 4 \\ 3 & 5 & 0 \end{pmatrix}$ and $b = \begin{pmatrix} 1 \\ 7 \end{pmatrix}$. Since $\operatorname{rank} A = \operatorname{rank} A_b = 2 < 3$ the system has an infinite number of solutions. In fact the set of solutions can be expressed as $\{\, (4 + 5a, -1 - 3a, a)^T \mid a \in \mathcal{R} \,\}$. Equivalently, it can be expressed as the affine subspace $\{\, (4, -1, 0)^T + a(5, -3, 1)^T \mid a \in \mathcal{R} \,\}$ of dimension $n - \operatorname{rank} A = 3 - 2 = 1$.

2. The system of linear equations

$$\begin{aligned} 5x_1 - 3x_2 + 4x_3 &= 4 \\ -x_2 + 5x_3 &= 7 \\ 3x_3 &= 6 \end{aligned}$$

has the upper triangular coefficient matrix $U = \begin{pmatrix} 5 & -3 & 4 \\ 0 & -1 & 5 \\ 0 & 0 & 3 \end{pmatrix}$. Using Algorithm 2, the unique solution is $x_3 = \frac{6}{3} = 2$, $x_2 = \frac{1}{-1}(7 - 5 \cdot 2) = 3$, $x_1 = \frac{1}{5}(4 - (-3) \cdot 3 - 4 \cdot 2) = 1$.

6.4.2 GAUSSIAN ELIMINATION

Solving a system of linear equations via Gaussian elimination is one of the most common computations performed by scientists and engineers. Gaussian elimination successively eliminates variables from the original system, creating a triangular system that is easily solved (§6.4.1).

Note: This subsection deals only with linear systems $Ax = b$, where A is a nonsingular $n \times n$ real matrix and $b \in \mathcal{R}^n$.

Definitions:

Gaussian elimination is a method for solving systems of linear equations; at each step, one equation is used to eliminate one variable from the rest of the equations. The coefficient of the eliminated variable in the eliminated equation is the ***pivot***.

A ***flop*** is a multiply-add operation of the form $t = s + ab$, especially when performed in floating point arithmetic on a digital computer.

Roundoff errors are the errors associated with storing and computing numbers in finite precision arithmetic on a digital computer.

A ***numerically stable algorithm*** is a method whose accuracy is not greatly harmed by roundoff errors.

A ***numerically unstable algorithm*** is a method that may return an inaccurate solution even when the solution is relatively insensitive to errors in the data.

Facts:

1. Gaussian elimination is easily extended to linear systems for which the data A and b are complex. Extension to rectangular $m \times n$ linear systems is more involved, but not difficult [GoVL13].

2. In Gaussian elimination, the coefficient of a variable in one of the equations can be used as a pivot if and only if its value is nonzero.

3. In practice, careful choice of pivots is needed to ensure accuracy or improve efficiency or both. (See Example 2.)

4. Assume freedom at each step to choose any available nonzero pivot. Then Gaussian elimination succeeds (using exact arithmetic) if and only if A is nonsingular.

5. Gaussian elimination transforms the initial linear system into a second linear system such that

- the solutions of the two systems are identical;
- the solution of the second system is easily obtained by back substitution.

6. $Ax = b$ can be solved by Gaussian elimination and back substitution (Algorithm 3), assuming that at each step there is a nonzero pivot on the main diagonal.

```
Algorithm 3: Gaussian elimination and back substitution.
  input: $n \times n$ nonsingular matrix $A$, $n \times 1$ vector $b$
  output: $n \times 1$ vector $x = A^{-1}b$
  {Gaussian elimination}
  for $j := 1$ to $n - 1$
     {$a_{jj}$ is the pivot}
     for $i := j + 1$ to $n$
        {Eliminate $x_j$ from equation $i$}
        compute multiplier $m := -a_{ij}/a_{jj}$
        add $m \times$ row $j$ to row $i$
  {Back substitution}
  use Algorithm 2 on the resulting upper triangular matrix to obtain the values
     $x_n, x_{n-1}, \ldots, x_1$
```

7. Algorithm 3, implemented to take advantage of created 0s, requires $\frac{1}{3}n^3 + O(n^2)$ flops.

8. To solve $Ax = b$ by computing the inverse and then forming the product $A^{-1}b$ requires $n^3 + O(n^2)$ flops.

9. *Cramer's rule*: This method for solving $Ax = b$ expresses each entry of the solution $x = (x_1, x_2, \ldots, x_n)^T$ as the ratio of two determinants:

$$x_1 = \frac{\det A_1}{\det A},\ x_2 = \frac{\det A_2}{\det A}, \ldots,\ x_n = \frac{\det A_n}{\det A},$$

where A_i is obtained from A by substituting column vector b for the ith column of A. (Gabriel Cramer, 1704–1752)

10. Cramer's rule is of extremely limited use numerically because

- it requires far more flops than Gaussian elimination and back substitution;
- it is numerically unstable.

Examples:

1. The following system is solved by first applying Gaussian elimination:

$$\begin{aligned} x_1 + x_2 + 2x_3 + x_4 &= 1 \\ 2x_1 + 4x_2 + 5x_3 + 4x_4 &= 5 \quad (-\tfrac{2}{1} \times \text{equation 1}) \\ x_1 + 7x_2 + 7x_3 + 6x_4 &= 6 \quad (-\tfrac{1}{1} \times \text{equation 1}) \\ 2x_1 + 4x_2 + 9x_3 + 5x_4 &= 3 \quad (-\tfrac{2}{1} \times \text{equation 1}) \end{aligned}$$

$$\begin{aligned} x_1 + x_2 + 2x_3 + x_4 &= 1 \\ 2x_2 + x_3 + 2x_4 &= 3 \\ 6x_2 + 5x_3 + 5x_4 &= 5 \quad (-\tfrac{6}{2} \times \text{equation 2}) \\ 2x_2 + 5x_3 + 3x_4 &= 1 \quad (-\tfrac{2}{2} \times \text{equation 2}) \end{aligned}$$

$$\begin{aligned} x_1 + x_2 + 2x_3 + x_4 &= 1 \\ 2x_2 + x_3 + 2x_4 &= 3 \\ 2x_3 - x_4 &= -4 \\ 4x_3 + x_4 &= -2 \quad (-\tfrac{4}{2} \times \text{equation 3}) \end{aligned}$$

$$\begin{aligned} x_1 + x_2 + 2x_3 + x_4 &= 1 \\ 2x_2 + x_3 + 2x_4 &= 3 \\ 2x_3 - x_4 &= -4 \\ 3x_4 &= 6 \end{aligned}$$

The solution is then obtained by back substitution:

$$\begin{aligned} x_4 &= 6/3 = 2, \\ x_3 &= [-4 + 1 \cdot 2]/2 = -1, \\ x_2 &= [3 - 1 \cdot (-1) - 2 \cdot 2]/2 = 0, \\ x_1 &= [1 - 1 \cdot 0 - 2 \cdot (-1) - 1 \cdot 2]/1 = 1. \end{aligned}$$

2. Suppose the following system is solved, rounding all results to three significant digits:

$$\begin{aligned} 0.0001x_1 + x_2 &= 1 \\ 0.5x_1 + 0.5x_2 &= 1 \quad (-\tfrac{0.5}{0.0001} \times \text{equation 1}) \end{aligned}$$

$$\begin{aligned} 0.0001x_1 + x_2 &= 1 \\ -5000x_2 &= -5000 \end{aligned}$$

Using back substitution produces $x_2 = 1$ and $x_1 = 0$. However, the correct solution to this simple linear system is $x_1 = \frac{10000}{9999}$ and $x_2 = \frac{9998}{9999}$, which to three significant digits becomes $x_1 = 1$ and $x_2 = 1$. Consequently, simply choosing any nonzero pivot can produce inaccurate results.

6.4.3 *LU* DECOMPOSITION

Gaussian elimination can be formulated as *LU* decomposition of the coefficient matrix.

Definitions:

An ***LU decomposition*** of a square matrix A expresses $A = LU$, where $L = (l_{ij})$ is unit lower triangular and $U = (u_{ij})$ is upper triangular.

A ***permutation matrix*** is a square matrix with entries 0 or 1, where the entry 1 occurs precisely once in each row and once in each column.

Facts:

1. A square matrix has an LU decomposition if and only if every principal submatrix (§6.3.1) is nonsingular.

2. If P is a permutation matrix, then the product PA rearranges the rows of A and the product AP rearranges the columns of A.

3. The matrix A is nonsingular if and only if there exists a permutation matrix P such that PA has an LU decomposition. The LU decomposition of PA is unique.

4. It may be necessary to rearrange the rows of A to avoid a zero pivot.

5. Assume A has an LU decomposition, and consider Gaussian elimination applied to $Ax = b$ with pivots on the main diagonal. The following statements express LU decomposition as a reformulation of Gaussian elimination:

- the entry u_{ij} $(1 \leq i \leq j \leq n)$ is the coefficient of x_j in equation i after Gaussian elimination has been completed;
- to eliminate x_j from equation i, $i > j$, Gaussian elimination adds $-l_{ij}\times$ equation j to equation i.

6. If A has an LU decomposition, then the linear system $Ax = b$ can be solved as follows (see Algorithm 4):

- compute the decomposition $A = LU$;
- solve $Ly = b$; that is, perform forward substitution;
- solve $Ux = y$; that is, perform back substitution.

7. It is inefficient to solve a nontrivial sequence of linear systems $Ax_1 = b_1$, $Ax_2 = b_2, \ldots,$ $Ax_p = b_p$ by repeating Gaussian elimination for each system. Only one LU decomposition is needed, followed by p forward substitution steps and p back substitution steps.

8. An LU decomposition of an $n \times n$ matrix requires $n^2 + O(n)$ storage locations and $\frac{1}{3}n^3 + O(n^2)$ flops.

Algorithm 4: ***LU* decomposition with forward and back substitution.**

```
input: $n \times n$ nonsingular matrix $A$, $n \times 1$ vector $b$
output: $n \times 1$ vector $x = A^{-1}b$
{Compute $A = LU$}
for $k := 1$ to $n - 1$
  $u_{kk} := a_{kk}$
  for $i := k + 1$ to $n$
    $l_{ik} := a_{ik}/a_{kk}$; $u_{ki} := a_{ki}$
  for $j := k + 1$ to $n$
    for $i := k + 1$ to $n$
      $a_{ij} := a_{ij} - l_{ik}u_{kj}$
{Solve $Ly = b$; that is, perform forward substitution}
```

```
for $i := 1$ to $n$
    $y_i := b_i - \sum_{j=1}^{i-1} l_{ij} y_j$
{Solve $Ux = y$; that is, perform back substitution}
for $i := n$ down to $1$
    $x_i := \frac{1}{u_{ii}} \Big( y_i - \sum_{j=i+1}^{n} u_{ij} x_j \Big)$
```

Examples:

1. The following matrix A has no LU decomposition because $a_{11} = 0$ (see Fact 1):

$$A = \begin{pmatrix} 0 & 1 \\ 2 & 3 \end{pmatrix}.$$

However, rearranging the rows of A (Fact 4) produces

$$PA = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 2 & 3 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 2 & 3 \\ 0 & 1 \end{pmatrix} = LU.$$

2. The unique LU decomposition of the matrix A in Example 1, §6.4.2 is

$$\begin{pmatrix} 1 & 1 & 2 & 1 \\ 2 & 4 & 5 & 4 \\ 1 & 7 & 7 & 6 \\ 2 & 4 & 9 & 5 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 \\ 1 & 3 & 1 & 0 \\ 2 & 1 & 2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 & 2 & 1 \\ 0 & 2 & 1 & 2 \\ 0 & 0 & 2 & -1 \\ 0 & 0 & 0 & 3 \end{pmatrix}.$$

6.4.4 CHOLESKY DECOMPOSITION

For symmetric positive definite linear systems, Cholesky decomposition (which exploits symmetry in the coefficient matrix) is roughly twice as efficient as LU decomposition.

Definition:

A ***Cholesky decomposition*** of A expresses $A = LL^T$, where L is lower triangular and every entry on the main diagonal of L is positive.

Facts:

1. A matrix has a Cholesky decomposition if and only if it is symmetric and positive definite.

2. When A is symmetric and positive definite, the linear system $Ax = b$ can be solved as follows:

- compute a Cholesky decomposition $A = LL^T$;
- solve $Ly = b$; i.e., perform forward substitution;
- solve $L^T x = y$; i.e., perform back substitution.

3. A simple symmetric variant of the standard LU decomposition algorithm is used to compute Cholesky decomposition [GoVL13, St88].

4. Cholesky decomposition requires $\frac{1}{2}n^2+O(n)$ storage locations and $\frac{1}{6}n^3+O(n^2)$ flops, in contrast to the $n^2+O(n)$ storage locations and $\frac{1}{3}n^3+O(n^2)$ flops required by LU decomposition.

Example:

1. The matrix $A = \begin{pmatrix} 1 & -1 & 3 \\ -1 & 2 & -1 \\ 3 & -1 & 14 \end{pmatrix}$ is clearly symmetric. It is positive definite since its principal submatrices (1), $\begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$, and A have positive determinants. (See §6.3.4, Fact 22.) Matrix A can be written as $A = LL^T$, where L is the lower triangular matrix $\begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 3 & 2 & 1 \end{pmatrix}$. To solve the linear system $Ax = b$ with $b = (1,0,6)^T$, first solve the lower triangular system $Ly = b$, yielding $y = (1,1,1)^T$. Then solve the upper triangular system $L^Tx = y$, yielding $x = (-3,-1,1)^T$.

6.4.5 CONDITIONING OF LINEAR SYSTEMS

Errors in the data A and b lead to errors in the solution x. The *condition number* of A can be used to bound relative error in the solution in terms of relative errors in the data.

Definitions:

A (***generalized***) ***vector norm*** on $\mathcal{R}^n$ is a real-valued function $\|\cdot\|$ satisfying the following properties for all real scalars a and all vectors $x, y \in \mathcal{R}^n$:

- $\|x\| \geq 0$ with equality if and only if $x = 0$;
- $\|ax\| = |a| \cdot \|x\|$, where $|a|$ denotes the absolute value of a;
- $\|x+y\| \leq \|x\| + \|y\|$.

The ***matrix norm*** induced by the vector norm $\|\cdot\|$ is defined by $\|A\| = \max_{\|x\|=1} \|Ax\|$.

The ***condition number*** of a nonsingular matrix A is the number $\kappa(A) = \|A\|\,\|A^{-1}\|$. The larger the condition number of a matrix, the more ***ill conditioned*** it is; the smaller the condition number of a matrix, the more ***well conditioned*** it is.

Facts:

1. The definition of a vector norm given here generalizes that of a vector norm derived from an inner product space (§6.1.4).

2. The matrix norm induced by a vector norm satisfies

- $\|X\| \geq 0$ with equality if and only if $X = 0$;
- $\|aX\| = |a| \cdot \|X\|$, where $|a|$ denotes the absolute value of a;
- $\|X+Y\| \leq \|X\| + \|Y\|$;
- $\|XY\| \leq \|X\|\|Y\|$.

3. $\kappa(A) \geq 1$.

4. Consider the linear system $Ax = b \neq 0$, where A is nonsingular. Suppose that changing from A to $A + \Delta A$ and b to $b + \Delta b$ changes the solution from x to $x + \Delta x$. If $\|(\Delta A)\|\,\|A^{-1}\| < 1$, the relative error in x can be bounded in terms of relative errors in the data:

$$\frac{\|\Delta x\|}{\|x\|} \leq \left(\frac{\kappa(A)}{1 - \|(\Delta A)\|\,\|A^{-1}\|}\right)\left(\frac{\|\Delta b\|}{\|b\|} + \frac{\|\Delta A\|}{\|A\|}\right).$$

5. The following are consequences of Fact 4:

- For an ill-conditioned linear system $Ax = b$, *some* small errors in A or b can potentially be amplified into large errors in x;
- For a well-conditioned linear system $Ax = b$, where $1 - \|(\Delta A)\|\,\|A^{-1}\|$ is not approximately zero, *all* small errors in A or b result in no more than modest errors in x.

6. Assume A is nonsingular, let $Ax = b \neq 0$, and view $\hat{x}$ as an approximation to the solution x. Then the residual $r = A\hat{x} - b$ and the error $\hat{x} - x$ satisfy

$$\frac{\|\hat{x} - x\|}{\|x\|} \leq \kappa(A)\frac{\|r\|}{\|b\|}.$$

7. Whenever A is ill conditioned, a small relative residual $\|r\|/\|b\|$ may not imply a small relative error $\|\hat{x} - x\|/\|x\|$.

Examples:

1. The standard Euclidean norm (§6.1.4) on $\mathcal{R}^n$ defined by $\|x\|_2 = (\sum\limits_{i=1}^{n} x_i^2)^{1/2}$ is a (generalized) vector norm.

2. The l_1 norm on $\mathcal{R}^n$ defined by $\|x\|_1 = \sum\limits_{i=1}^{n} |x_i|$ is a (generalized) vector norm.

3. In coding theory (§14.1), the *Hamming distance* between two codewords $x, y \in \mathcal{Z}_2^n$ is just $\|x - y\|_1$.

4. The l_∞ norm on $\mathcal{R}^n$ defined by $\|x\|_\infty = \max\limits_{1 \leq i \leq n} |x_i|$ is a (generalized) vector norm.

5. The matrix norm induced by $\|x\|_1$ is given by $\|A\|_1 = \max\limits_{1 \leq j \leq n} \sum\limits_{i=1}^{n} |a_{ij}|$.

6. The matrix norm induced by $\|x\|_\infty$ is given by $\|A\|_\infty = \max\limits_{1 \leq i \leq n} \sum\limits_{j=1}^{n} |a_{ij}|$.

7. The matrix norm induced by $\|x\|_2$, also called the *spectral norm*, is given by $\|A\|_2 = \max\{\sqrt{\lambda} \mid \lambda$ an eigenvalue of $A^T A\}$.

8. Consider the linear system $Ax = b$, where $A = \begin{pmatrix} 1 & 2 \\ 2.001 & 4 \end{pmatrix}$ and $b = \begin{pmatrix} 2 \\ 4 \end{pmatrix}$. Then $\|A\|_\infty = 6.001$ and $\|A^{-1}\|_\infty = 3{,}000$, so that $\kappa(A) = 18{,}003$. The solution of $Ax = b$ is $x = (0, 1)^T$ whereas the solution of the slightly perturbed system with $\hat{b} = \begin{pmatrix} 2 \\ 4.001 \end{pmatrix}$ is $x = (1, 0.5)^T$. Even though the change in the right-hand side is small, the large condition number allows for radical changes in the solution vector, as seen here.

6.4.6 PIVOTING FOR STABILITY

Gaussian elimination can be numerically unstable. Numerical stability can be vastly improved by the addition of pivoting strategies that select large pivots.

Definitions:

Let $a_{ij}^{(k)}$ denote the ij-entry of the current matrix after step k of Gaussian elimination (or LU decomposition). The ***growth factor*** is defined by $\dfrac{\max\limits_{i,j,k} |a_{ij}^{(k)}|}{\max\limits_{i,j} |a_{ij}|}$.

Partial pivoting is a solution strategy which at step k of Gaussian elimination exchanges row k with the row $i \geq k$ having the entry of largest magnitude in column k.

Complete pivoting is a solution strategy which at step k of Gaussian elimination exchanges row k and column k with, respectively, the row $i \geq k$ and the column $j \geq k$ containing the entry of largest magnitude.

Facts:

1. For general coefficient matrices, Gaussian elimination (that is, LU decomposition) without pivoting is numerically unstable.

2. To improve the numerical stability of Gaussian elimination, it suffices to introduce a pivoting strategy that keeps the growth factor small.

3. For Gaussian elimination with complete pivoting the growth factor is bounded above by

$$n^{1/2}\big(2^1 3^{1/2} 4^{1/3} \ldots n^{1/(n-1)}\big)^{1/2},$$

which is a relatively slow-growing function of n; hence, Gaussian elimination with complete pivoting is numerically stable.

4. For Gaussian elimination with partial pivoting, the growth factor is bounded above by 2^{n-1}, and moreover there are contrived examples for which the growth factor is 2^{n-1}. Hence, Gaussian elimination with partial pivoting can be numerically unstable.

5. In practice, partial pivoting is preferred over complete pivoting for the following two reasons:

- Despite contrived examples having an exponential growth factor, partial pivoting limits the growth factor in practice almost as well as complete pivoting;
- Partial pivoting is significantly more efficient than complete pivoting; it compares $\frac{1}{2}n^2 + O(n)$ pairs of potential pivots, while complete pivoting compares $\frac{1}{3}n^3 + O(n^2)$ pairs.

Example:

1. LU decomposition applied to the following matrix shows that partial pivoting can produce a growth factor of 2^{n-1} (see Fact 4). Observe that $\max_{i,j} |a_{ij}| = 1$ and $\max_{i,j,k} |a_{ij}^{(k)}| = u_{nn} = 2^{n-1}$; hence the growth factor is 2^{n-1}.

$$\begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & 1 \\ -1 & 1 & 0 & \cdots & 0 & 1 \\ -1 & -1 & 1 & \cdots & 0 & 1 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ -1 & -1 & -1 & \cdots & 0 & 1 \\ -1 & -1 & -1 & \cdots & 1 & 1 \\ -1 & -1 & -1 & \cdots & -1 & 1 \end{pmatrix}$$

6.4.7 PIVOTING TO PRESERVE SPARSITY

Many, if not most, linear systems that arise in practice have relatively few nonzero entries in the coefficient matrix. Some pivoting strategies aim to preserve many zero entries in the triangular factors; the LU decomposition algorithm can then save time and space by omitting zero entries from the computation.

Definitions:

A matrix is ***sparse*** if it has relatively few nonzero entries. The number of nonzero entries of matrix A is denoted $|A|$. The ith row of A is denoted $A(i,:)$ and the jth column of A is denoted $A(:,j)$. (See §6.3.1.)

Fill refers to nonzero entries in the triangular factors whose corresponding positions in the coefficient matrix are occupied by zeros.

The ***upper bandwidth*** and ***lower bandwidth*** of a matrix A are given respectively by $\mathrm{ub}(A) = \max\{\,(j-i) \mid a_{ij} \neq 0,\ i<j\,\}$, $\mathrm{lb}(A) = \max\{\,(i-j) \mid a_{ij} \neq 0,\ i>j\,\}$.

A ***banded*** LU decomposition algorithm stores and computes all entries of L and U within the band defined by $\mathrm{lb}(A)$ and $\mathrm{ub}(A)$.

A ***general sparse*** LU decomposition algorithm stores and computes only the nonzero entries in the triangular factors, irrespective of the banded structure.

The ***Markowitz pivoting strategy*** for Gaussian elimination chooses at step k from among all available pivots one that minimizes the product $\big(|L(:,k)|-1\big)\big(|U(k,:)|-1\big)$.

The ***minimum degree algorithm*** is a restricted version of the Markowitz pivoting strategy; it assumes (and preserves) symmetry in the coefficient matrix. At step k of Gaussian elimination, this algorithm chooses from among the entries on the main diagonal a pivot that minimizes $|L(:,k)|$.

Note: The realistic "no-cancellation" assumption will be made throughout. Namely, once an entry becomes nonzero during a triangular decomposition, it will be nonzero upon termination.

Facts:

1. The amount of fill in triangular factors often varies greatly with the choice of pivots.

2. Under the no-cancellation assumption, bandwidth reduction and fill reduction become combinatorial optimization problems.

3. The following problems are provably intractable (i.e., NP-hard; see §17.5):

- for a symmetric matrix A, find a permutation matrix P that minimizes the bandwidth $\mathrm{lb}(PAP^T)$;

- for a nonsingular matrix A, find permutation matrices P and Q such that the LU decomposition $PAQ = LU$ exists and $|L| + |U|$ is minimum;
- for a symmetric positive definite matrix A, find a permutation matrix P that minimizes $|L|$, where L is the Cholesky factor of PAP^T.

4. In view of Fact 3, various heuristics are used to reduce bandwidth or to reduce fill.

5. Assume that A has an LU decomposition. Then $\mathrm{lb}(L) = \mathrm{lb}(A)$ and $\mathrm{ub}(U) = \mathrm{ub}(A)$.

6. The chief advantage of a banded LU decomposition algorithm over a general sparse LU decomposition algorithm is its simplicity. The same advantage holds for *profile* and *skyline* methods, both of which are generalizations of the banded approach [GeLi81].

7. For most problems encountered in practice, a banded LU decomposition algorithm, even if A has been permuted so that $\mathrm{lb}(A)$ and $\mathrm{ub}(A)$ are minimum, requires much more space and work than a general sparse LU decomposition algorithm coupled with the Markowitz pivoting strategy. The same comment applies to profile and skyline methods.

8. Let A be a symmetric positive definite matrix, and let P be a permutation matrix with the same number of rows and columns.

- the Cholesky decomposition of PAP^T exists and is numerically stable;
- the undirected graph (§8.1) G of the Cholesky factor of PAP^T is a *chordal graph* and P defines a *perfect elimination ordering* of G [GeLi81].

9. General sparse Cholesky decomposition can be handled in a clean, modular fashion:

- using only the positions of nonzeros in A as input, compute a permutation P to reduce fill in the Cholesky factor of PAP^T (using, for example, the minimum degree algorithm);
- construct data structures to contain the nonzeros of the Cholesky factor;
- after putting the nonzero entries of PAP^T into the data structures, compute the Cholesky factor of PAP^T in the provided data structures;
- perform forward and back substitutions to solve the linear system.

10. For symmetric positive definite matrices arising from two-dimensional and three-dimensional partial differential equations, the *nested dissection* algorithm often computes a more effective fill-reducing permutation than does the minimum degree algorithm [GeLi81].

11. The interplay between pivoting for stability and pivoting for sparsity complicates general sparse LU factorization. The best approach is not yet certain.

12. A number of robust and well-tested software packages for solving linear systems are available at

- `http://www.mathworks.com`
- `http://www.nag.com`
- `http://www.netlib.org`
- `http://www.roguewave.com`

Examples:

1. For any "arrowhead" matrix there is a pivot sequence that completely fills the matrix and another that creates no fill, making it the canonical example used to illustrate Fact 1. The following is a 4×4 arrowhead matrix that fills in completely. (Here $\star$ occupies a position that is nonzero in A, $\bullet$ is a fill entry in L or U, and a space is a zero.)

$$A = \begin{pmatrix} \star & \star & \star & \star \\ \star & \star & & \\ \star & & \star & \\ \star & & & \star \end{pmatrix}, \qquad A = LU = \begin{pmatrix} \star & & & \\ \star & \star & & \\ \star & \bullet & \star & \\ \star & \bullet & \bullet & \star \end{pmatrix} \begin{pmatrix} \star & \star & \star & \star \\ & \star & \bullet & \bullet \\ & & \star & \bullet \\ & & & \star \end{pmatrix}.$$

Reversing the pivot sequence, however, results in no fill:

$$\widehat{A} = PAP^T = \begin{pmatrix} & & & 1 \\ & & 1 & \\ & 1 & & \\ 1 & & & \end{pmatrix} \begin{pmatrix} \star & \star & \star & \star \\ \star & \star & & \\ \star & & \star & \\ \star & & & \star \end{pmatrix} \begin{pmatrix} & & & 1 \\ & & 1 & \\ & 1 & & \\ 1 & & & \end{pmatrix} = \begin{pmatrix} \star & & & \star \\ & \star & & \star \\ & & \star & \star \\ \star & \star & \star & \star \end{pmatrix},$$

$$\widehat{A} = \widehat{L}\widehat{U} = \begin{pmatrix} \star & & & \\ & \star & & \\ & & \star & \\ \star & \star & \star & \star \end{pmatrix} \begin{pmatrix} \star & & & \star \\ & \star & & \star \\ & & \star & \star \\ & & & \star \end{pmatrix}.$$

2. The following table illustrates how Fact 7 typically manifests itself in practice. The four problems arise in finite element modeling of actual structures. The table records data for two distinct methods:

- a profile-reducing permutation from the reverse Cuthill-McKee algorithm [GeLi81] in tandem with a profile factorization algorithm;
- a fill-reducing permutation from the minimum degree algorithm [GeLi81] in tandem with a general sparse factorization algorithm.

Recorded for each method are the number of nonzero entries in the Cholesky factor (expressed in millions) and the number of flops needed to compute the factor (expressed in millions).

problem	n	$\lvert A\rvert$	$\lvert L\rvert$ $(\times 10^{-6})$		*No. flops* $(\times 10^{-6})$	
			profile reduction	*general sparse*	*profile reduction*	*general sparse*
coliseum	1,806	63,454	0.190	0.112	11.803	4.952

6.5 EIGENANALYSIS

Identifying the eigenvalues and eigenvectors of a matrix facilitates the study of complicated systems and the analysis of their behavior over time. A basis consisting of eigenvectors yields a particularly simple representation of a linear transformation (§6.2). Eigenvalues can also provide useful information about discrete structures (§8.10.2).

6.5.1 EIGENVALUES AND CHARACTERISTIC POLYNOMIALS

Definitions:

A complex number λ is an ***eigenvalue*** of the $n \times n$ complex matrix A if there exists a nonzero vector $x \in \mathcal{C}^n$ (an ***eigenvector*** of A corresponding to λ) such that $Ax = \lambda x$.

The ***characteristic polynomial*** of the square matrix A is the polynomial $p_A(\lambda) = \det(\lambda I - A)$.

The ***characteristic equation*** of A is the equation $p_A(\lambda) = 0$.

A ***nilpotent*** matrix is a square matrix A such that $A^k = 0$ for some positive integer k.

An ***idempotent*** matrix is a square matrix A such that $A^2 = A$.

Let $S_k(A)$ denote the sum of all order k principal minors of the matrix A.

Facts:

1. The characteristic polynomial $p_A(\lambda)$ of an $n \times n$ matrix A is a monic polynomial of degree n in λ.

2. The coefficient of λ^{n-1} in $p_A(\lambda)$ is $-\mathrm{tr}\, A$.

3. The constant term in $p_A(\lambda)$ is $(-1)^n \det A$.

4. $p_A(\lambda) = \sum_{k=0}^{n} (-1)^k S_k(A) \lambda^{n-k}$.

5. Similar matrices (§6.2.4) have the same characteristic polynomial.

6. The roots of the characteristic equation are the eigenvalues of A.

7. *Cayley-Hamilton theorem*: If $p_A(\cdot)$ is the characteristic polynomial of A then $p_A(A)$ is the zero matrix.

8. An $n \times n$ matrix has n (not necessarily distinct) eigenvalues.

9. The matrix A is singular if and only if 0 is an eigenvalue of A.

10. The characteristic equation of $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is $p_A(\lambda) = \lambda^2 - (a+d)\lambda + (ad - bc)$.

11. The eigenvalues of $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ are given by $\dfrac{(a+d) \pm \sqrt{(a-d)^2 + 4bc}}{2}$.

12. If the $n \times n$ matrix A has eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_n$ then

- $\sum_{i=1}^{n} \lambda_i = \mathrm{tr}\, A$;
- $\prod_{i=1}^{n} \lambda_i = \det A$;
- the kth elementary symmetric function $\sum_{i_1 < \cdots < i_k} \lambda_{i_1} \ldots \lambda_{i_k}$ equals $S_k(A)$.

13. The eigenvalues are continuous functions of the entries of a matrix. More precisely, given an $n\times n$ matrix A with eigenvalues $\lambda_1,\lambda_2,\ldots,\lambda_n$ and $\epsilon>0$, there exists $\delta>0$ such that for any $n\times n$ matrix B, with eigenvalues $\mu_1,\mu_2,\ldots,\mu_n$ and satisfying $\max_{i,j}|a_{ij}-b_{ij}|<\delta$, there exists a permutation τ of $1,2,\ldots,n$ such that $|\lambda_i-\mu_{\tau(i)}|<\epsilon$, $i=1,2,\ldots,n$.

14. The following table gives the eigenvalues of certain specialized matrices A, whose eigenvalues are $\lambda_1,\lambda_2,\ldots,\lambda_n$. In this table k is any positive integer.

matrix	*eigenvalues*
diagonal matrix	diagonal elements
upper (or lower) triangular matrix	diagonal elements
A^T	eigenvalues of A
A^*	complex conjugates of the eigenvalues of A
A^k	$\lambda_1^k,\ldots,\lambda_n^k$
A^{-k}, A nonsingular	$\lambda_1^{-k},\ldots,\lambda_n^{-k}$
$q(A)$, where $q(\cdot)$ is a polynomial	$q(\lambda_1),\ldots,q(\lambda_n)$
SAS^{-1}, S nonsingular	eigenvalues of A
AB, where A is $m\times n$, B is $n\times m$, $m\geq n$	eigenvalues of BA; and 0 ($m-n$ times)
$(a-b)I_n+bJ_n$, where J_n is the $n\times n$ matrix of all 1s	$a+(n-1)b$; and $a-b$ ($n-1$ times)
A $n\times n$ nilpotent	0 (n times)
A $n\times n$ idempotent of rank r	1 (r times); and 0 ($n-r$ times)

Examples:

1. The characteristic polynomial for $A=\begin{pmatrix}1&4\\2&3\end{pmatrix}$ is $p_A(\lambda)=\begin{vmatrix}\lambda-1&-4\\-2&\lambda-3\end{vmatrix}=\lambda^2-4\lambda-5=(\lambda+1)(\lambda-5)$, so the eigenvalues are $\lambda=-1$ and $\lambda=5$. The vector $x=(2,-1)^T$ is an eigenvector for $\lambda=-1$ since $Ax=(-2,1)^T=-x$. The vector $x=(1,1)^T$ is an eigenvector for $\lambda=5$ since $Ax=(5,5)^T=5x$.

2. For the matrix in Example 1,

$$p_A(A)=A^2-4A-5I=\begin{pmatrix}9&16\\8&17\end{pmatrix}-\begin{pmatrix}4&16\\8&12\end{pmatrix}-\begin{pmatrix}5&0\\0&5\end{pmatrix}=\begin{pmatrix}0&0\\0&0\end{pmatrix},$$

as required by Fact 7.

3. The characteristic polynomial of the matrix $A=\begin{pmatrix}3&0&2\\4&1&4\\2&0&3\end{pmatrix}$ can be calculated by using Facts 1–4. Since $\operatorname{tr}A=7$, $\det A=5$, and $S_2(A)=\begin{vmatrix}1&4\\0&3\end{vmatrix}+\begin{vmatrix}3&2\\2&3\end{vmatrix}+\begin{vmatrix}3&0\\4&1\end{vmatrix}=11$, it follows that $p_A(\lambda)=\lambda^3-7\lambda^2+11\lambda-5$. Thus $p_A(5)=0$, showing that $\lambda=5$ is an eigenvalue of A. An eigenvector corresponding to $\lambda=5$ is $x=(1,2,1)^T$ since $Ax=(5,10,5)^T=5x$.

4. The matrix A in Example 3 is nonsingular since $p_A(0) \neq 0$, so 0 is not an eigenvalue of A (Fact 9). The inverse of A can be calculated using the Cayley-Hamilton theorem: $A^3 - 7A^2 + 11A - 5I = 0$, so $5I = A^3 - 7A^2 + 11A = A(A^2 - 7A + 11I)$ and $I = A[\frac{1}{5}(A^2 - 7A + 11I)]$. Consequently, $A^{-1} = \frac{1}{5}(A^2 - 7A + 11I) = \frac{1}{5}\begin{pmatrix} 3 & 0 & -2 \\ -4 & 5 & -4 \\ -2 & 0 & 3 \end{pmatrix}$.

6.5.2 EIGENVECTORS AND DIAGONALIZATION

Definitions:

Let λ be an eigenvalue of the $n \times n$ (complex) matrix A. The ***algebraic multiplicity*** of λ is its multiplicity as a root of the characteristic polynomial.

The ***eigenspace*** of A corresponding to λ is the vector space $\{\, x \in \mathcal{C}^n \mid Ax = \lambda x \,\}$.

The ***geometric multiplicity*** of λ is the dimension of the eigenspace of A corresponding to λ.

The square matrix A is ***diagonalizable*** if there exists a nonsingular matrix P such that $P^{-1}AP$ is a diagonal matrix.

The ***minimal polynomial*** of the square matrix A is the monic polynomial $q(\cdot)$ of minimum degree such that $q(A) = 0$.

The square matrix A is ***normal*** if $AA^* = A^*A$.

The ***singular values*** of an $n \times n$ matrix A are the (positive) square roots of the eigenvalues of AA^*, written $\sigma_1(A) \leq \sigma_2(A) \leq \cdots \leq \sigma_n(A)$.

A ***row stochastic*** matrix is a matrix with all entries nonnegative and row sums 1.

Facts:

1. The eigenspace corresponding to λ is a subspace of the vector space $\mathcal{C}^n$. Specifically, it is the null space (§6.1.2) of the matrix $A - \lambda I$.

2. Eigenvectors corresponding to distinct eigenvalues are linearly independent.

3. If λ, μ are distinct eigenvalues of A and if $Ax = \lambda x$ and $A^*y = \mu y$, then x, y are orthogonal.

4. The algebraic multiplicity is never less than the geometric multiplicity, but sometimes it is greater. (See Example 3.)

5. The minimal polynomial is unique.

6. If A can be diagonalized to a diagonal matrix D, then the eigenvalues of A appear along the diagonal of D.

7. The following conditions are equivalent for an $n \times n$ matrix A:

- A is diagonalizable;
- A has n linearly independent eigenvectors;
- the minimal polynomial of A has distinct linear factors;
- the algebraic multiplicity of each eigenvalue of A equals its geometric multiplicity.

8. If the $n \times n$ matrix A has n distinct eigenvalues then A is diagonalizable.

9. If the $n \times n$ matrix A has n linearly independent eigenvectors $v_1, v_2, \dots, v_n$ then A is diagonalizable using the matrix P whose columns are the vectors $v_1, v_2, \dots, v_n$.

10. Hermitian, skew-Hermitian, and unitary matrices are normal matrices.

11. *Spectral theorem for normal matrices*: If A is an $n \times n$ normal matrix, then it can be diagonalized by a unitary matrix. That is, there exists an $n \times n$ unitary matrix U such that $U^*AU = \operatorname{diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$, the diagonal matrix with the eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_n$ of A along its diagonal.

12. If A is normal, then it has a *spectral decomposition* $A = \sum_{i=1}^{n} \lambda_i u_i u_i^*$, where $\{u_1, u_2, \dots, u_n\}$ is an orthonormal basis for $\mathcal{C}^n$.

13. Diagonalization results for special types of normal matrices are given in the following table.

matrix A	*eigenvalues*	*diagonalization result*
Hermitian	real	Fact 11
real symmetric	real	there exists a real orthogonal P such that P^TAP is diagonal
skew-Hermitian	purely imaginary	Fact 11
real skew-symmetric	purely imaginary	there exists a real orthogonal Q such that Q^TAQ is a direct sum of matrices, each of which is a 2×2 real skew-symmetric or null matrix
unitary	all with modulus 1	Fact 11

14. If A, B are normal and commute, they can be simultaneously diagonalized. Namely, there exists a unitary U such that U^*AU and U^*BU are both diagonal.

15. For any square matrix A, the rank of A is never less than the number of nonzero eigenvalues (counting multiplicities) of A.

16. If A is normal then its rank equals the number of nonzero eigenvalues.

17. *Schur's triangularization theorem*: Suppose A is a square matrix. Then there exists a unitary U such that U^*AU is upper triangular with the eigenvalues of A on its diagonal.

18. If A, B are square matrices that commute then there exists a unitary U such that U^*AU and U^*BU are both upper triangular.

19. *Jordan canonical form*: Let A be an $n \times n$ matrix with the distinct eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_k$ having (algebraic) multiplicities $r_1, r_2, \dots, r_k$ respectively. Then there exists a nonsingular matrix P such that $P^{-1}AP = \operatorname{diag}(\Lambda_1, \Lambda_2, \dots, \Lambda_k)$, where

$$\Lambda_i = \begin{pmatrix} \lambda_i & * & 0 & \cdots & 0 & 0 \\ 0 & \lambda_i & * & \cdots & 0 & 0 \\ \vdots & \vdots & & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_i & * \\ 0 & 0 & 0 & \cdots & 0 & \lambda_i \end{pmatrix}$$

is an $r_i \times r_i$ matrix and each $*$ is either 0 or 1. Furthermore, the number of 1s is r_i minus the geometric multiplicity of λ_i.

20. The rank of a square matrix equals the number of nonzero singular values.

21. If A is a square matrix and if U and V are unitary, then A and UAV have the same singular values.

22. *Singular value decomposition*: If A is an $n \times n$ matrix then there exist $n \times n$ unitary matrices U, V such that UAV is diagonal with $\sigma_1(A), \sigma_2(A), \ldots, \sigma_n(A)$ on the diagonal.

23. *QR factorization*: If A is an $n \times n$ matrix then there exists a unitary matrix Q and an upper triangular matrix R such that $A = QR$.

24. The QR factorization of a matrix can be calculated using Gram-Schmidt orthogonalization (§6.1.4).

Examples:

1. Let x, y be vectors of size $n \times 1$ and let $A = xy^T$. Then the eigenvalues of A are given by $y^T x$ and 0, the latter with multiplicity $n-1$.

2. The matrix given in Example 3, §6.5.1 has the characteristic polynomial $p_A(\lambda) = \lambda^3 - 7\lambda^2 + 11\lambda - 5 = (\lambda-1)^2(\lambda-5)$. The eigenvalues are $\lambda = 1$ with algebraic multiplicity 2 and $\lambda = 5$ with algebraic multiplicity 1.

For $\lambda = 1$ the eigenspace is the null space of $A - \lambda I = \begin{pmatrix} 2 & 0 & 2 \\ 4 & 0 & 4 \\ 2 & 0 & 2 \end{pmatrix}$. It consists of all vectors of the form $(a, b, -a)^T$ and so is spanned by the linearly independent eigenvectors $(1, 0, -1)^T$ and $(0, 1, 0)^T$. Thus the geometric multiplicity of $\lambda = 1$ is 2, the same as its algebraic multiplicity 1.

As seen in Example 3 of §6.5.1, the eigenvalue $\lambda = 5$ has the eigenvector $(1, 2, 1)^T$, linearly independent of the previous two eigenvectors (Fact 2). If $P = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 2 \\ -1 & 0 & 1 \end{pmatrix}$ is the matrix containing these eigenvectors then $P^{-1}AP = \text{diag}(1, 1, 5)$, thereby diagonalizing A (Fact 9).

3. By using *Maple*, the characteristic polynomial of the matrix

$$A = \begin{pmatrix} 7 & 2 & 4 & 0 & 3 \\ 0 & 6 & 0 & 0 & 0 \\ 0 & -2 & 4 & 0 & 0 \\ 3 & 2 & 4 & 4 & 3 \\ 3 & 0 & 2 & 0 & 7 \end{pmatrix}$$

is found to be $\lambda^5 - 28\lambda^4 + 300\lambda^3 - 1552\lambda^2 + 3904\lambda - 3840 = (\lambda-4)^3(\lambda-6)(\lambda-10)$, so the eigenvalue $\lambda = 4$ of A has algebraic multiplicity 3. The eigenspace for $\lambda = 4$ is the null space of

$$A - \lambda I = \begin{pmatrix} 3 & 2 & 4 & 0 & 3 \\ 0 & 2 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 & 0 \\ 3 & 2 & 4 & 0 & 3 \\ 3 & 0 & 2 & 0 & 3 \end{pmatrix},$$

which is spanned by $(1, 0, 0, -1)^T$ and $(0, 0, 0, 1, 0)^T$. So $\lambda = 4$ has geometric multiplicity 2. By Fact 7, A is not diagonalizable. The minimal polynomial of A is $(\lambda-4)^2(\lambda-6)(\lambda-10)$, which has the repeated linear factor $\lambda - 4$.

4. The conclusion of Fact 16 need not hold if A is not normal. For example, the matrix $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ has rank 1 but has no nonzero eigenvalues.

5. *Matrix powers*: The matrix $A = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{3}{4} & \frac{1}{4} \end{pmatrix}$ is a row stochastic matrix and the powers A^n of such matrices are important in the analysis of Markov chains (§7.7). The eigenvalues of A are $\lambda = 1$ and $\lambda = -\frac{1}{4}$, with corresponding eigenvectors $(1,1)^T$ and $(2,-3)^T$. Thus $P^{-1}AP = D = \text{diag}(1, -\frac{1}{4})$, where $P = \begin{pmatrix} 1 & 2 \\ 1 & -3 \end{pmatrix}$. Consequently $A = PDP^{-1}$, $A^2 = PDP^{-1}PDP^{-1} = PD^2P^{-1}$, and in general $A^n = PD^nP^{-1}$. Since $D^n = \text{diag}(1^n, (-\frac{1}{4})^n) = \text{diag}(1, \alpha^n)$, the nth power of A can be computed as $A^n = \frac{1}{5}\begin{pmatrix} 3+2\alpha^n & 2-2\alpha^n \\ 3-3\alpha^n & 2+3\alpha^n \end{pmatrix}$. Since $|\alpha| < 1$, $A^n \to \begin{pmatrix} \frac{3}{5} & \frac{2}{5} \\ \frac{3}{5} & \frac{2}{5} \end{pmatrix}$ as $n \to \infty$.

6.5.3 LOCALIZATION

Since analytic computation of eigenvalues can be complicated, there are several simple methods available for (geometrically) estimating the eigenvalues of a matrix. These methods can be informative in cases when only the approximate location of eigenvalues is needed.

Definitions:

The ***spectral radius*** of A, $\rho(A)$, is the maximum modulus of an eigenvalue of A.

Let A be an $n \times n$ matrix and let $\alpha_i = \sum\limits_{j \neq i} |a_{ij}|$, $i = 1, 2, \ldots, n$.

The ***Geršgorin discs*** associated with A are the discs

$$\{\, z \in \mathcal{C} \mid |z - a_{ii}| \le \alpha_i \,\}, \quad i = 1, 2, \ldots, n.$$

The ***ovals of Cassini*** associated with A are the ellipses

$$\{\, z \in \mathcal{C} \mid |z - a_{ii}||z - a_{jj}| \le \alpha_i \alpha_j \,\}, \quad i \neq j.$$

A ***strictly diagonally dominant*** matrix is a square matrix A satisfying $|a_{ii}| > \alpha_i$ for $i = 1, 2, \ldots, n$.

Facts:

1. $\rho(A)$ is the radius of the smallest disc, centered at the origin of the complex plane, enclosing all of the eigenvalues of A.

2. $\rho(A) \le \min\{\max\limits_i \sum_j |a_{ij}|, \max\limits_j \sum_i |a_{ij}|\}$.

3. The spectral radius of a row stochastic matrix is 1.

4. All the eigenvalues of A are contained in the union of the associated Geršgorin discs.

5. A connected region formed by precisely $k \le n$ Geršgorin discs contains exactly k eigenvalues of A.

6. All the eigenvalues of A are contained in the union of the $\frac{n(n-1)}{2}$ ovals of Cassini associated with A.

Examples:

1. By Fact 2, the spectral radius of the symmetric matrix

$$A = \begin{pmatrix} 8 & -2 & 1 & 1 \\ -2 & -8 & -2 & -1 \\ 1 & -2 & 7 & 1 \\ 1 & -1 & 1 & 8 \end{pmatrix}$$

is bounded by the maximum absolute row (column) sum 13. Since the eigenvalues of a real symmetric matrix are real, the spectral radius bound gives the interval $[-13, 13]$ enclosing all eigenvalues. The Geršgorin discs are the intervals

$$8 \pm 4 = [4, 12],\ -8 \pm 5 = [-13, -3],\ 7 \pm 4 = [3, 11],\ 8 \pm 3 = [5, 11].$$

The second interval is disjoint from the others, so one eigenvalue is localized in the interval $[-13, -3]$ while the other three are in the interval $[3, 12]$. The actual eigenvalues of A are (approximately) $-8.51, 6.31, 7.03, 10.2$, consistent with the above intervals. Also, 0 is not in any of the four Geršgorin discs so 0 is not an eigenvalue and A is nonsingular. Since the eigenvalues of A^{-1} are the reciprocals of the eigenvalues of A (see §6.5.1), it follows that the eigenvalues of the symmetric matrix A^{-1} are localized to the intervals $[-\frac{1}{3}, -\frac{1}{13}]$ and $[\frac{1}{12}, \frac{1}{3}]$.

2. Using Fact 4, the eigenvalues of the matrix $A = \begin{pmatrix} 2 & 1 & -1 \\ 0 & 6 & 2 \\ 1 & -1 & 8 \end{pmatrix}$ are located in the union of the discs

$$D_1 = \{\, z \mid |z-2| \le 2 \,\},\ D_2 = \{\, z \mid |z-6| \le 2 \,\},\ D_3 = \{\, z \mid |z-8| \le 2 \,\}.$$

Since A and A^T have the same eigenvalues, an alternative set of disks can be formed based on the absolute *column* sums of A: namely

$$\widehat{D}_1 = \{\, z \mid |z-2| \le 1 \,\},\ \widehat{D}_2 = \{\, z \mid |z-6| \le 2 \,\},\ \widehat{D}_3 = \{\, z \mid |z-8| \le 3 \,\}.$$

Here $\widehat{D}_1$ is disjoint from both $\widehat{D}_2$ and $\widehat{D}_3$, and so one eigenvalue of A is localized to $\widehat{D}_1$, and the other two to $\widehat{D}_2 \cup \widehat{D}_3$. In fact, the eigenvalues of A are 2.24 and $6.88 \pm 0.91i$, approximately.

3. The row stochastic matrix $A = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{3}{4} & \frac{1}{4} \end{pmatrix}$ has Geršgorin discs

$$D_1 = \{\, z \mid |z - \frac{1}{2}| \le \frac{1}{2} \,\} \text{ and } D_2 = \{\, z \mid |z - \frac{1}{4}| \le \frac{3}{4} \,\}.$$

Since $D_1 \subseteq D_2$ all eigenvalues must lie in D_2. As seen in Example 5 of §6.5.2, the eigenvalues of A are 1 and $-\frac{1}{4}$.

4. Suppose A is strictly diagonally dominant. Then all Geršgorin discs for A reside in the positive right-half plane so all the eigenvalues must have positive real part. In particular, 0 is not an eigenvalue and A must be nonsingular.

5. If the $n \times n$ matrix A satisfies $a_{ii}a_{jj} > \alpha_i \alpha_j$ for all $i \ne j$ then A must be nonsingular, since by Fact 6 zero is not an eigenvalue of A. The matrix of Example 2 satisfies this condition since $a_{ii}a_{jj} \ge 12 > 4 = \alpha_i \alpha_j$ for all $i \ne j$, and so it must be nonsingular.

6.5.4 COMPUTATION OF EIGENVALUES

The eigenvalues of a matrix can be obtained, in theory, by forming the characteristic equation and finding its roots. Since this is not a practical solution method for problems of realistic size, a variety of iterative techniques have been developed.

Definitions:

A ***dominant*** eigenvalue of a matrix is an eigenvalue with the maximum modulus.

Let $U(\theta; i, j)$ be the $n \times n$ matrix obtained by replacing the 2×2 principal submatrix of the identity matrix, corresponding to rows i and j, with the rotation matrix

$$\begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix}.$$

Facts:

1. *Power method*: The power method (Algorithm 1) is a simple technique for finding the dominant eigenvalue and an associated eigenvector of a nonsingular matrix A having a unique dominant eigenvalue.

```
Algorithm 1: Power method.
  input: $n \times n$ nonsingular matrix $A$
  output: approximations $x_k$ to an eigenvector of $A$
  {Initialization}
  choose any vector $x_0 \in \mathcal{C}^n$ with $\|x_0\| = 1$
  {Iterative step}
  for $k := 1$ to ...
    $x_k := \dfrac{Ax_{k-1}}{\|Ax_{k-1}\|}$
```

2. In Algorithm 1, the kth estimate $x_k = \dfrac{A^k x_0}{\|A^k x_0\|}$.

3. The sequence x_k converges to an eigenvector of A.

4. The sequence $\|Ax_k\|$ approaches the dominant eigenvalue.

5. The power method is best suited for large sparse matrices.

6. The rate of convergence of the power method is dictated by the ratio of the largest to the second largest (in modulus) eigenvalue of A. The larger this ratio (the more separated these two eigenvalues in modulus), the faster the convergence of the method.

7. *QR method*: This method (Algorithm 2) calculates the eigenvalues of a given $n \times n$ matrix A.

```
Algorithm 2: QR method.
  input: $n \times n$ matrix $A$
  output: $n \times n$ matrices $A_k$
  {Initialization}
```

```
$A := Q_0 R_0$ (a $QR$ factorization of $A$)
{Iterative step}
for $k := 1$ to ...
    $A_k := R_{k-1} Q_{k-1}$
    obtain a $QR$ factorization $A_k = Q_k R_k$
```

8. The QR factorization in Algorithm 2 produces a unitary matrix Q_k and an upper triangular matrix R_k. (See §6.5.2, Fact 23.)

9. Under certain conditions (for example, if the eigenvalues of A have distinct moduli) the sequence A_k in Algorithm 2 converges to an upper triangular matrix whose diagonal entries are the eigenvalues of A.

10. If A is real then its QR factors are real and can be calculated using real arithmetic. In this case, if A has nonreal eigenvalues then under certain conditions, the limiting matrix is block triangular with 1 × 1 and 2 × 2 diagonal blocks.

11. The QR method is not well suited for large sparse matrices since the factors Q, R can quickly fill with nonzeros.

12. Often as a preparatory step for the QR method the matrix is first reduced to *Hessenberg form* (upper triangular form in which there may be one nonzero diagonal below the main diagonal) by using Householder transformations [Da95].

13. The convergence of the QR method can be very slow if the matrix has two eigenvalues that are close in moduli.

14. More effective versions of the QR method are available which make use of certain *shift strategies* [GoVL13].

15. *Jacobi method*: This method (Algorithm 3) finds the eigenvalues of a real symmetric $n \times n$ matrix A having at least one nonzero off-diagonal entry.

```
Algorithm 3: Jacobi method.
input: $n \times n$ real symmetric matrix $A$
output: $n \times n$ matrices $A_k$
{Initialization}
$A_1 = (a_{ij}^{(1)}) := A$
{Iterative step}
for $k := 1$ to ...
    choose $r, s$ $(r < s)$ with $|a_{rs}^{(k)}|$ as large as possible
    define $\theta$ by $\cot 2\theta = \dfrac{a_{rr}^{(k)} - a_{ss}^{(k)}}{2a_{rs}^{(k)}}$
    $A_{k+1} = (a_{ij}^{(k+1)}) := U(\theta; r, s)^T A_k\, U(\theta; r, s)$
```

16. The sequence A_k in Algorithm 3 converges to a real diagonal matrix with the eigenvalues of A on the diagonal.

17. The orthogonal matrix $U(\theta; r, s)$ represents a (clockwise) plane rotation by the angle θ.

18. The Jacobi method is particularly appropriate when A is nearly diagonal, although in general the QR method exhibits faster convergence.

19. A variant of the Jacobi method, the *serial Jacobi method*, uses plane rotation pairs cyclically—for example, $(1, 2), (1, 3), \ldots , (1, n), (2, 3), \ldots , (2, n), \ldots .$

20. For further information on numerical computation of eigenvalues, see [GoVL13, Da95].

21. A number of robust and well-tested software packages for carrying out eigensystem analysis are available at

Examples:

1. The power method, when applied to the matrix in Example 3 of §6.5.1, produces the following sequence of vectors x_k and scalars $\|Ax_k\|$:

k	0	1	2	3	4	5
x_k	$\begin{pmatrix}1\\0\\0\end{pmatrix}$	$\begin{pmatrix}0.557\\0.743\\0.371\end{pmatrix}$	$\begin{pmatrix}0.436\\0.805\\0.403\end{pmatrix}$	$\begin{pmatrix}0.414\\0.814\\0.407\end{pmatrix}$	$\begin{pmatrix}0.409\\0.816\\0.408\end{pmatrix}$	$\begin{pmatrix}0.409\\0.816\\0.408\end{pmatrix}$
$\|Ax_k\|$	5.385	5.537	5.107	5.021	5.004	5.001

The scalars $\|Ax_k\|$ approach the dominant eigenvalue 5 and the vectors x_k approach a multiple of the eigenvector $(1, 2, 1)^T$.

2. The eigenvalues of the matrix $A = \begin{pmatrix}1 & 4\\ 2 & 3\end{pmatrix}$ can be approximated using the QR method. $A = Q_0R_0$ with $Q_0 = \begin{pmatrix}-0.447 & -0.894\\ -0.894 & 0.447\end{pmatrix}$ and $R_0 = \begin{pmatrix}-2.236 & -4.472\\ 0 & -2.236\end{pmatrix}$. Then $A_1 = R_0Q_0 = \begin{pmatrix}5 & 0\\ 2 & -1\end{pmatrix}$. Continuing this process produces

$$A_2 = \begin{pmatrix}4.862 & 2.345\\ 0.345 & -0.862\end{pmatrix},\ A_3 = \begin{pmatrix}5.023 & -1.927\\ 0.073 & -1.023\end{pmatrix},\ A_4 = \begin{pmatrix}4.995 & 2.014\\ 0.014 & -0.995\end{pmatrix}.$$

The sequence A_k approaches an upper triangular matrix with the eigenvalues 5 and -1 on its diagonal.

3. The eigenvalues of the matrix $A = \begin{pmatrix}0 & 1 & 1\\ 1 & 4 & -3\\ 1 & -3 & 4\end{pmatrix}$ can be approximated using the Jacobi method. The largest off-diagonal $|a_{rs}|$ of $A_1 = A$ occurs for $r = 2$, $s = 3$ giving $\theta = \frac{\pi}{4} = 0.7854$. Applying the matrix $U(\theta; 2, 3) = \begin{pmatrix}1 & 0 & 0\\ 0 & 0.7071 & 0.7071\\ 0 & -0.7071 & 0.7071\end{pmatrix}$ produces $A_2 =$

$U(\theta;2,3)^T A_1\, U(\theta;2,3) = \begin{pmatrix} 0 & 0 & 1.4142 \\ 0 & 7 & 0 \\ 1.4142 & 0 & 1 \end{pmatrix}$. The largest magnitude off-diagonal entry of A_2 is $|a_{13}|$, giving $\theta = 0.6155$, $U(\theta;1,3) = \begin{pmatrix} 0.8165 & 0 & 0.5774 \\ 0 & 1 & 0 \\ -0.5774 & 0 & 0.8165 \end{pmatrix}$, and $A_3 = U(\theta;1,3)^T A_2\, U(\theta;1,3) = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 7 & 0 \\ 0 & 0 & 2 \end{pmatrix}$. So the eigenvalues of A are $-1, 2, 7$.

6.5.5 SPECIAL CLASSES

This section discusses eigenvalues and eigenvectors of specially structured matrices, such as Hermitian, positive definite, nonnegative, totally positive, and circulant matrices.

Definitions:

If $x, y \in \mathcal{R}^n$, then x ***majorizes*** y if $\sum_{i=1}^n x_i = \sum_{i=1}^n y_i$ and for $k = 1, 2, \ldots, n-1$ the sum of the k largest components of x is at least as large as the sum of the k largest components of y. A similar definition holds for infinite sequences with finitely many nonzero terms.

A Hermitian $n \times n$ matrix A is ***positive definite*** if $x^*Ax > 0$ for all nonzero $x \in \mathcal{C}^n$. It is ***positive semidefinite*** if $x^*Ax \geq 0$ for all $x \in \mathcal{C}^n$.

If A and B are $n \times n$ Hermitian matrices then A ***dominates*** B in ***Löwner order*** if $A - B$ is positive semidefinite, written $A \succeq B$.

A matrix is ***nonnegative*** (***positive***) if each of its entries is nonnegative (positive).

The $n \times n$ matrix A is ***reducible*** if either it is the 1×1 zero matrix or there exists a permutation matrix P such that PAP^T is of the form $\begin{pmatrix} B & 0 \\ C & D \end{pmatrix}$, where B and D are square. A matrix is ***irreducible*** if it is not reducible.

A ***strictly totally positive*** matrix has all of its minors positive.

A ***circulant*** matrix has the form

$$\begin{pmatrix} a_0 & a_1 & a_2 & \cdots & a_n \\ a_n & a_0 & a_1 & \cdots & a_{n-1} \\ a_{n-1} & a_n & a_0 & \cdots & a_{n-2} \\ \vdots & \vdots & \vdots & & \vdots \\ a_1 & a_2 & a_3 & \cdots & a_0 \end{pmatrix}.$$

Notation: Let $\lambda_1(A) \leq \lambda_2(A) \leq \cdots \leq \lambda_n(A)$ be the eigenvalues of an $n \times n$ Hermitian matrix A.

Facts:

1. *Cauchy's interlacing theorem*: Let A be an $n \times n$ Hermitian matrix and let B be a principal submatrix of A of order $n-1$. Then

$$\lambda_i(A) \leq \lambda_i(B) \leq \lambda_{i+1}(A), \quad i = 1, 2, \ldots, n-1.$$

2. *Weyl's theorem*: Let A, B be $n \times n$ Hermitian matrices and let j, k be integers satisfying $1 \le j,\ k \le n$.

- If $j + k \ge n + 1$, then $\lambda_{j+k-n}(A + B) \le \lambda_j(A) + \lambda_k(B)$;
- If $j + k \le n + 1$, then $\lambda_j(A) + \lambda_k(B) \le \lambda_{j+k-1}(A + B)$.

3. Interpretations of the kth smallest eigenvalue of a Hermitian matrix are given in the following table.

eigenvalue	*variational characterization*
$\lambda_1(A)$	$\min(x^*Ax)$, minimum over all unit vectors x
$\lambda_n(A)$	$\max(x^*Ax)$, maximum over all unit vectors x
$\lambda_k(A)$, $k = 2, \ldots, n$	$\min(x^*Ax)$, minimum over all unit vectors x orthogonal to the eigenspaces of $\lambda_1, \ldots, \lambda_{k-1}$
$\lambda_{n-k}(A)$, $k = 1, \ldots, n-1$	$\max(x^*Ax)$, maximum over all unit vectors x orthogonal to the eigenspaces of $\lambda_{n-k+1}, \ldots, \lambda_n$

4. *Schur's majorization theorem*: If A is an $n \times n$ Hermitian matrix, then $(\lambda_1(A), \lambda_2(A), \ldots, \lambda_n(A))$ majorizes $(a_{11}, a_{22}, \ldots, a_{nn})$. Specifically, if $a_{11} \ge a_{22} \ge \cdots \ge a_{nn}$ then

$$\sum_{i=1}^{k} \lambda_{n-i+1}(A) \ge \sum_{i=1}^{k} a_{ii}, \quad k = 1, 2, \ldots, n.$$

5. *Hoffman-Wielandt theorem*: If A, B are $n \times n$ Hermitian matrices, then

$$\sum_{i=1}^{n} (\lambda_i(A + B) - \lambda_i(A))^2 \le \sum_{i,j=1}^{n} |b_{ij}|^2.$$

6. *Sylvester's law of inertia*: If A is an $n \times n$ Hermitian matrix and if X is a nonsingular $n \times n$ matrix, then A and X^TAX have the same number of positive eigenvalues as well as the same number of negative eigenvalues.

7. A Hermitian matrix is positive definite (positive semidefinite) if and only if all its eigenvalues are positive (nonnegative).

8. If A, B are $n \times n$ positive semidefinite matrices and $A \succeq B$, then $\lambda_i(A) \ge \lambda_i(B)$, $i = 1, 2, \ldots, n$.

9. If A, B are $n \times n$ positive semidefinite matrices, then $\lambda_{i+j-n}(AB) \le \lambda_i(A)\lambda_j(B)$ holds for $1 \le i,\ j \le n$ and $i + j \ge n + 1$.

10. If A, B are $n \times n$ positive semidefinite matrices, then

$$\prod_{i=1}^{k} \lambda_i(AB) \ge \prod_{i=1}^{k} \lambda_i(A)\lambda_i(B), \quad k = 1, 2, \ldots, n.$$

11. *Kantorovich inequality*: If A is an $n \times n$ positive definite matrix and if $x \in \mathcal{C}^n$ is a unit vector, then

$$(x^*Ax)(x^*A^{-1}x) \le \frac{(\lambda_1(A) + \lambda_n(A))^2}{4\lambda_1(A)\lambda_n(A)}.$$

12. *Perron-Frobenius theorem*: If A is an irreducible nonnegative square matrix, then the spectral radius of A (the *Perron root* of A) is an eigenvalue of A with algebraic multiplicity 1 and it has an associated positive eigenvector. If A is positive then the spectral radius exceeds the modulus of any other eigenvalue.

13. If A is a nonnegative square matrix, then the spectral radius of A is an eigenvalue of A and it has an associated nonnegative eigenvector.

14. Let A be an $n \times n$ strictly totally positive matrix. Then the eigenvalues of A are distinct and positive: $\lambda_1(A) < \lambda_2(A) < \cdots < \lambda_n(A)$. The real eigenvector corresponding to λ_{n-k} has exactly k variations in sign.

15. If A is an $n \times n$ strictly totally positive matrix, then $(\lambda_1(A), \lambda_2(A), \ldots, \lambda_n(A))$ majorizes $(a_{11}, a_{22}, \ldots, a_{nn})$.

16. An $(n+1) \times (n+1)$ circulant matrix has eigenvalues $\lambda_j = a_0 + a_1\omega^j + a_2\omega^{2j} + \cdots + a_n\omega^{nj}$, $j = 0, 1, \ldots, n$ with $(1, \omega^j, \omega^{2j}, \ldots, \omega^{nj})$, $j = 0, 1, \ldots, n$ the corresponding eigenvectors, where $\omega = e^{\frac{2\pi i}{n+1}}$.

Examples:

1. The matrix $A = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 4 & -3 \\ 1 & -3 & 4 \end{pmatrix}$ has eigenvalues -1, 2, and 7 (§6.5.4, Example 3). The principal submatrix $A[1,2] = \begin{pmatrix} 0 & 1 \\ 1 & 4 \end{pmatrix}$ has eigenvalues $2 \pm \sqrt{5}$, which are approximately equal to -0.2361 and 4.2361. As required by Fact 1, these latter two eigenvalues interlace those of A: $-1 \le -0.2361 \le 2 \le 4.2361 \le 7$. Similarly, the principal submatrix $A[2,3] = \begin{pmatrix} 4 & -3 \\ -3 & 4 \end{pmatrix}$ has eigenvalues 1 and 7, which interlace those of A.

2. The matrix in Example 1 has the eigenvalue sequence $(-1, 2, 7)$. This sequence majorizes (see Fact 4) the sequence $(0, 4, 4)$ of diagonal elements: $7 \ge 4$, $7 + 2 \ge 4 + 4$, and $7 + 2 - 1 \ge 4 + 4 + 0$.

3. The irreducible matrix A in Example 3 of §6.5.3 is positive with eigenvalues 1 and $-\frac{1}{4}$. Thus $\rho(A) = 1$ and it exceeds the modulus of any other eigenvalue. As required by Fact 12, there is a positive eigenvector associated with $\lambda = 1$, namely $(1,1)^T$.

4. The matrix $A = \begin{pmatrix} 2 & 0 & 3 \\ 1 & 4 & 5 \\ 2 & 0 & 1 \end{pmatrix}$ is nonnegative with eigenvalues -1 (algebraic multiplicity 1) and 4 (algebraic multiplicity 2). So the spectral radius is 4 and (see Fact 13) $\lambda = 4$ must be an eigenvalue. In addition, there is a nonnegative eigenvector associated with $\lambda = 4$, namely $(0,1,0)^T$.

6.6 COMBINATORIAL MATRIX THEORY

Matrices and graphs represent two different ways of viewing certain discrete structures. At times a matrix perspective can lend insight into graphical or combinatorial structures. At other times the graph associated with a matrix can provide useful information about matrix properties.

6.6.1 MATRICES OF ZEROS AND ONES

Definitions:

A ***$(0,1)$-matrix*** is a matrix with each entry either 0 or 1.

The ***term rank*** $\rho_t(A)$ of a $(0,1)$-matrix A is the maximum number of 1s such that no two are in the same row or column.

An $n \times n$ $(0,1)$-matrix is ***partly decomposable*** if it has a $k \times (n-k)$ zero submatrix for some $1 \leq k \leq n-1$; otherwise A is ***fully indecomposable***.

For vectors $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$ we say that x is ***majorized*** by y (§6.5.5) if the sum of the k largest components in x is no more than the sum of the k largest components in y for $k \leq n$, with equality for $k = n$. This is denoted by $x \preceq y$.

A vector $x = (x_1, x_2, \ldots, x_n)$ is ***monotone*** if $x_1 \geq x_2 \geq \cdots \geq x_n$. If $R = (r_1, r_2, \ldots, r_m)$ is a vector of nonnegative integers with $r_i \leq n$, then its ***conjugate*** vector is $R^* = (r_1^*, r_2^*, \ldots, r_n^*)$ where r_i^* is the number of r_j with value no less than i. Thus R^* is monotone.

For nonnegative integral vectors $R = (r_1, r_2, \ldots, r_m)$ and $S = (s_1, s_2, \ldots, s_n)$ define $\mathcal{A}(R, S)$ as the class of $(0,1)$-matrices $A = (a_{ij})$ with row sum vector R and column sum vector S, i.e., $\sum_{j=1}^{n} a_{ij} = r_i$ $(i \leq m)$ and $\sum_{i=1}^{m} a_{ij} = s_j$ $(j \leq n)$. We may assume $\sum_i r_i = \sum_j s_j$. Using permutations of rows and columns one may assume that R and S are monotone. Then the ***structure matrix*** of $\mathcal{A}(R, S)$ is the $(m+1) \times (n+1)$ matrix T with entries $t_{kl} = kl - \sum_{j=1}^{l} s_j + \sum_{i=k+1}^{m} r_i$ $(0 \leq k \leq m,\ 0 \leq l \leq n)$.

An $n \times n$ $(0,1)$-matrix $A = (a_{ij})$ satisfying $a_{ii} = 0$ for $i \leq n$ and $a_{ij} + a_{ji} = 1$ for $1 \leq i < j \leq n$ is called a ***tournament*** matrix. Its row sum vector is called the ***score vector***, and it records the number of wins of each player in a round-robin tournament where $a_{ij} = 1$ means that Player i won against Player j.

Facts:

1. *König's theorem*: The term rank $\rho_t(A)$ of a $(0,1)$-matrix A equals the minimum number of rows and columns required to cover all 1s in the matrix.

2. $\text{rank}(A) \leq \rho_t(A)$.

3. *Frobenius-König theorem*: Let A be an $n \times n$ $(0,1)$-matrix. Then the term rank of A is less than n if and only if A has a zero submatrix of size $r \times s$ with $r + s = n + 1$.

4. Let A be an $n \times n$ $(0,1)$-matrix each of whose row sums and column sums is k. Then A can be expressed as a sum of k permutation matrices (§6.4.3).

5. Let A be a square $(0,1)$-matrix and let B be the matrix obtained from A by replacing each 0 entry on the main diagonal of A by 1. Then A is irreducible (§6.5.5) if and only if B is fully indecomposable.

6. Let A, B be $n \times n$ fully indecomposable matrices. Then the matrix obtained by replacing every nonzero entry in AB by 1 is fully indecomposable.

7. *Gale-Ryser theorem*: Let $R = (r_1, r_2, \ldots, r_m)$ and $S = (s_1, s_2, \ldots, s_n)$ be nonnegative integral vectors with $r_i \leq n$ and $s_j \leq m$. Then the class $\mathcal{A}(R, S)$ is nonempty (i.e., there is an $m \times n$ $(0,1)$-matrix $A = (a_{ij})$ with row sum vector R and column sum vector S) if and only if $S \preceq R^*$.

8. The class $\mathcal{A}(R, S)$ contains a unique matrix if and only if $S = R^*$.

9. Let $T = (t_{kl})$ be the structure matrix of a nonempty class $\mathcal{A}(R,S)$ and let $A \in \mathcal{A}(R,S)$. Let A_1 be the leading $k \times l$ submatrix of A, and let A_2 be the submatrix corresponding to rows $k+1,\ldots,m$ and columns $l+1,\ldots,n$. Then t_{kl} equals the number of zeros in A_1 plus the number of ones in A_2.

10. *Ford-Fulkerson theorem*: Suppose R and S are as in Gale-Ryser, with R and S monotone. Then the class $\mathcal{A}(R,S)$ is nonempty if and only if the structure matrix T is nonnegative.

11. *Ryser's theorem*: If A and B are distinct matrices in $\mathcal{A}(R,S)$, then B can be obtained from A by a sequence of interchanges; each such interchange replaces a 2×2 identity matrix I_2 (a submatrix of A) by the matrix obtained by complementing zeros and ones, or vice versa.

12. *Landau's theorem*: Let $R = (r_1, r_2, \ldots, r_n)$ be a monotone nonnegative integral vector. Then there exists a tournament matrix with score vector R if and only if $\sum_{i=1}^{k} r_i \ge \binom{k}{2}$ $(1 \le k \le n)$, with equality for $k = n$.

13. *Hardy-Littlewood-Pólya theorem*: If $x, y \in \mathcal{R}^n$, then $x \preceq y$ if and only if there is a doubly stochastic matrix (§6.6.3) A with $x = Ay$.

Examples:

1. The following matrix contains a 2×4 zero submatrix, occurring in rows 1, 3 and columns 1, 2, 4, 5. By Fact 3, this means that the matrix must have term rank less than 5. In fact, the matrix has term rank 3. Namely, the starred entries represent a set of 3 entries, no two of which are in the same row or column, and 3 is the largest number of nonzero entries with this property. Rows $2, 4$ and column 3 cover all the 1s in the matrix, and no smaller number suffices, as guaranteed by Fact 1, and $\rho_t(A) = 3$.

$$\begin{pmatrix} 0 & 0 & 1^* & 0 & 0 \\ 1^* & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 1^* \\ 0 & 0 & 1 & 0 & 0 \end{pmatrix}.$$

2. The matrix

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$$

has all row and column sums equal to 3. By Fact 4, it can be expressed as the sum of three permutation matrices. For example

$$A = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

3. *Assignment problem*: There are n applicants for n vacant jobs. Each applicant is qualified for exactly $k \ge 1$ jobs and for each job there are exactly k qualified applicants. Is it possible to assign each applicant to a (distinct) job for which the applicant is qualified? To answer this question form the $(0,1)$-matrix A where $a_{ij} = 1$ if applicant i is qualified for job j, otherwise $a_{ij} = 0$. All row and column sums of A equal k, so (by Fact 4) A

can be expressed as the sum of $k \geq 1$ permutation matrices. Select any one of these permutation matrices and use it to define an assignment of applicants to jobs. Thus it *is* possible in this case to fill each job with a different qualified applicant.

4. Let

$$\bar{A} = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad A = \begin{pmatrix} 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 0 \end{pmatrix}.$$

Both these matrices have row sum vector $R = (6, 5, 5, 4, 4)$. The column sum vector of $\bar{A}$ is $S(\bar{A}) = (5, 5, 5, 5, 3, 1, 0, 0)$ which is equal to the conjugate R^* of R. The column sum vector of A is $S = (4, 4, 3, 3, 3, 3, 2, 2)$, so $A \in \mathcal{A}(R, S)$. The majorization $S \preceq R^*$ holds (Fact 7). $\bar{A}$ is the unique matrix in the class $\mathcal{A}(R, R^*)$.

5. The matrix

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

is a tournament matrix with score vector $(3, 1, 1, 1)$. It may represent a round-robin tournament where Player 1 wins against all the others while, e.g., Player 2 only defeats Player 3.

6.6.2 MATRICES AND GRAPHS

Different matrices may be used to represent graphs and directed graphs. This makes it possible to use linear algebra and related fields, such as optimization, to investigate graph properties and problems formulated in terms of graphs.

Definitions:

Let G be a simple graph G with vertices $1, 2, \ldots, n$ and edges $e_1, e_2, \ldots, e_m$. The ***adjacency matrix*** of G is the square $(0, 1)$-matrix A_G of size $n \times n$ where $A_G(i, j)$ is 1 if vertices i and j are adjacent, and 0 otherwise. The ***incidence matrix*** of G is the $(0, 1)$-matrix $M_{I,G}$ of size $n \times m$ where $M_{I,G}(i, j)$ is 1 if vertex i is incident with edge e_j, and is 0 otherwise.

The ***Laplacian matrix*** L_G of G is defined as $L_G = D_G - A_G$ where D_G is the diagonal matrix whose diagonal entry d_i is the degree of vertex i, and A_G is the adjacency matrix of G.

Let D be a directed graph with vertices $1, 2, \ldots, n$ and arcs $e_1, e_2, \ldots, e_m$; we assume no parallel edges and no loops. The ***adjacency matrix*** of D is the square $(0, 1)$-matrix A_D where $A_D(i, j)$ is 1 if there is an arc with tail i and head j, and 0 otherwise. The ***incidence matrix*** of D is the $n \times m$ $(0, \pm 1)$-matrix $M_{I,D}$ where $M_{I,D}(i, j)$ is 1 (resp. -1) if vertex i is the head (resp. tail) of arc e_j, and is 0 otherwise.

An ***oriented incidence matrix*** of a simple graph G is the incidence matrix of the directed graph D obtained by some orientation of each of its edges.

A matrix A is called ***totally unimodular*** if the determinant of every square submatrix of A (i.e., a minor) is 0 or ±1.

A ***polyhedron*** is a set of the form $\{x \in \mathcal{R}^n \mid Ax \le b\}$ for some real $m \times n$ matrix A and $b \in \mathcal{R}^m$, i.e., it is the solution set of a linear inequality system.

A ***polytope*** P is the convex hull of a finite set of vectors, say $x_1, x_2, \ldots, x_k$ in $\mathcal{R}^n$, so it consists of all convex combinations $\sum_{i=1}^{k} c_i x_i$ where $c_i \ge 0$ $(1 \le i \le k)$, $\sum_{i=1}^{k} c_i = 1$. An ***extreme point*** of P is a point in P which cannot be written as a convex combination of other points in P.

The ***graph*** $G(A)$ of a symmetric $n \times n$ matrix $A = (a_{ij})$ is the graph with vertices $1, 2, \ldots, n$ and an edge $\{i, j\}$ whenever $a_{ij} \ne 0$.

Facts:

1. If D is a directed graph, $A_D^k = A_D \cdots A_D$ (k times) is the matrix whose (i,j)th entry equals the number of directed walks of length k from vertex i to vertex j in the graph G.

2. Two graphs G and G' on n vertices are isomorphic if and only if there is a permutation matrix P such that $A_G = PA_{G'}P^T$.

3. For a graph G, $M_{I,G}M_{I,G}^T = D_G + A_G$.

4. For a directed graph D, $M_{I,D}M_{I,D}^T = D_G - A_G$.

5. If G is a graph and $M_{I,D}$ is an oriented incidence matrix of G, then $M_{I,D}M_{I,D}^T = D_G - A_G = L_G$.

6. For every graph G the matrix L_G is symmetric and positive semidefinite, and the multiplicity of 0 as an eigenvalue of L_G equals the number of connected components of G.

7. If μ_G is the vector of the eigenvalues of L_G (n eigenvalues, if G has n vertices), then the following majorizations hold: $d_G \preceq \mu_G \preceq d_G^*$, where d_G is the degree vector of G and d_G^* is its conjugate vector (§6.6.1).

8. If a graph G with n vertices is connected then (any) oriented incidence matrix has rank $n-1$. More generally, if G has k connected components, then the rank is $n-k$.

9. *Matrix-tree theorem* (§8.10.2): For any graph G the absolute value of the determinant of any $(n-1) \times (n-1)$ submatrix of the Laplacian matrix L_G equals the number of spanning trees in G.

10. If D is a directed graph, then its incidence matrix $M_{I,D}$ is totally unimodular.

11. If G is a simple graph, then its incidence matrix $M_{I,G}$ is totally unimodular if and only if G is bipartite.

12. Every polyhedron is a convex set (so it is closed under taking convex combinations).

13. *Farkas-Minkowski-Weyl theorem*: A set P is a polytope if and only if P is a bounded polyhedron.

14. *Integrality theorem*: If A is totally unimodular, and b, b', c, c' are integral vectors with $b \le b'$ and $c \le c'$, then the polytope $\{x \mid b \le Ax \le b',\ c \le c \le c'\}$ has only integral extreme points.

15. If G is a bipartite graph, then the matching polytope, defined as the convex hull of the incidence vectors of matchings (§10.2.1) in G, equals $\{x \mid M_{I,G}\, x \le 1,\ 0 \le x \le 1\}$, where 0 and 1 are the zero vector and the all ones vector, respectively. This follows from the integrality theorem.

16. The minimum rank of a symmetric matrix A satisfying $G(A) = G$, where G is a given matrix, can be computed when G is a tree.

Examples:

1. Let G be the graph with vertices $1, 2, 3, 4$ and edges $\{1,2\}$, $\{2,3\}$, $\{3,4\}$, $\{1,4\}$, $\{2,4\}$. Its adjacency matrix A_G, incidence matrix $M_{I,G}$ (with this edge ordering), and Laplacian matrix L_G are

$$A_G = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}, \quad M_{I,G} = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 \end{pmatrix}, \quad L_G = \begin{pmatrix} 2 & -1 & 0 & -1 \\ -1 & 3 & -1 & -1 \\ 0 & -1 & 2 & -1 \\ -1 & -1 & -1 & 3 \end{pmatrix}.$$

The determinant of each 3×3 submatrix of L_G is ± 8, so the number of spanning trees of G is 8.

2. An oriented incidence matrix for the graph G above is

$$M_{I,D} = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 \\ -1 & 1 & 0 & 0 & 1 \\ 0 & -1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 & -1 \end{pmatrix}.$$

$M_{I,D}$ is totally unimodular while $M_{I,G}$ is not. As G contains an odd cycle, the submatrix of $M_{I,G}$ consisting of rows $2, 3, 4$ and columns $2, 3, 5$ has determinant 2 (Fact 11).

3. For the graph G in Example 1, the degree vector is $d_G = (2, 3, 2, 3)$, its conjugate is $d_G^* = (4, 4, 2, 0)$, and the vector of eigenvalues of the Laplacian matrix is $\mu_G = (4, 4, 2, 0)$. So, in this case $\mu_G = d_G^*$. This equality always holds for the class of *threshold graphs*; such graphs are constructed by starting with the empty graph and successively adding either isolated vertices or a vertex connected to all previous vertices. The graph G in Example 1 is a threshold graph.

4. Let D be a directed graph with n vertices and m edges. Also, let $b \in \mathcal{R}^n$ with $\sum_{i=1}^n b_i = 0$ and let $d \in \mathcal{R}^m$ be nonnegative. Any vector in the polyhedron $P_{D,b} := \{x \mid M_{I,D}x = b,\ 0 \leq x \leq d\}$ is called a *network flow*. The variable x_e represents the flow from tail to head of the arc e, and the linear equations assure that the difference between the flow into a vertex and the flow out of the same vertex is constant, and equal to the corresponding entry of b. The vector d represents arc capacities. If b and d are integral, then the extreme points of $P_{D,b}$ are integral. The linear optimization problem $\min\{c^T x \mid x \in P_{D,b}\}$ is known as the *minimum cost network flow problem* (§10.5.1) and it has many important applications.

6.6.3 NONNEGATIVE MATRICES

This subsection discusses nonnegative matrices and special classes of nonnegative matrices such as primitive and doubly stochastic matrices. Certain results highlight the relationship between the Perron root (§6.5.5, Fact 12) and the directed graph of a matrix.

Definitions:

The ***directed graph*** $G(A)$ of an $n \times n$ matrix A consists of n vertices $1, 2, \ldots, n$ with an arc from i to j if and only if $a_{ij} \neq 0$.

Vertices i and j of $G(A)$ are ***equivalent*** if $i = j$ or if there is a path in $G(A)$ from i to j and a path from j to i. The corresponding equivalence classes (§1.4.2) of this relation are the ***classes*** of A.

Class C_i has ***access*** to class C_j if $i = j$ or if there is a path in $G(A)$ from a vertex in C_i to a vertex in C_j. A class is ***final*** if it has access to no other class. Class C_i is ***basic*** if $\rho(A[C_i]) = \rho(A)$, where $\rho(\cdot)$ is the spectral radius (§6.5.3) and $A[C_i]$ is the principal submatrix of A defined by indices in class C_i.

Let A be an $n \times n$ nonnegative irreducible matrix. The number h of eigenvalues of A of modulus $\rho(A)$ is called the ***index of cyclicity*** of A. The matrix A is ***primitive*** if $h = 1$.

The ***exponent*** of A, written $\exp(A)$, is the least positive integer m with $A^m > 0$.

A square matrix is ***doubly stochastic*** if it is nonnegative and all row and column sums are 1.

If A is an $n \times n$ matrix and $\sigma \in S_n$, the symmetric group on n elements (§5.3.1), then the set $\{a_{1\sigma(1)}, a_{2\sigma(2)}, \ldots, a_{n\sigma(n)}\}$ is the ***diagonal*** of A corresponding to σ.

A diagonal of A is ***positive*** if each entry in it is positive.

Matrices A and B of the same size have the same ***pattern*** if the following condition holds: $a_{ij} = 0$ if and only if $b_{ij} = 0$.

The matrix A has a ***doubly stochastic pattern*** if there exists a doubly stochastic matrix B such that A and B have the same pattern.

An $n \times n$ matrix is called ***completely positive*** if $A = BB^T$ for some nonnegative $n \times k$ matrix.

Facts:

1. The matrix A is irreducible if and only if $G(A)$ is strongly connected (§8.3.2).

2. *Frobenius normal form*: If the $n \times n$ matrix A has k classes, then there exists a permutation matrix P such that

$$PAP^T = \begin{pmatrix} A_{11} & 0 & \cdots & 0 \\ A_{21} & A_{22} & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ A_{k1} & A_{k2} & \cdots & A_{kk} \end{pmatrix}$$

where each A_{ii}, $1 \le i \le k$, is either irreducible or a 1×1 zero matrix.

3. The classes of a nonnegative $n \times n$ matrix A are in one-to-one correspondence with the strong components (§8.3.2) of $G(A)$ and hence can be found in linear time.

4. Let A be an $n \times n$ nonnegative matrix. There is a positive eigenvector corresponding to $\rho(A)$ if and only if the basic classes of A are the same as its final classes.

5. Let A be an $n \times n$ nonnegative matrix with eigenvalue λ. There exists a nonnegative eigenvector for λ if and only if there exists a class C_i satisfying both of the following:

- $\rho(A[C_i]) = \lambda$;
- if C_j $(j \neq i)$ is any class that has access to C_i, then $\rho(A[C_j]) < \rho(A[C_i])$.

6. The $n \times n$ nonnegative matrix A is primitive if and only if $\exp(A) < \infty$.

7. A nonnegative irreducible matrix with positive trace is primitive.

8. Suppose A is an $n \times n$ nonnegative irreducible matrix. Let S_i be the set of all the lengths of cycles in $G(A)$ passing through vertex i, and let h_i be the greatest common divisor of all the elements of S_i. Then $h_1 = h_2 = \cdots = h_n$ and this common value equals the index of cyclicity of A.

9. Let A be a nonnegative irreducible $n \times n$ matrix with $p \geq 1$ nonzero elements on the main diagonal. Then A is primitive and $\exp(A) \leq 2n - p - 1$.

10. Let A be a primitive $n \times n$ matrix, and let s be the smallest length of a directed cycle in $G(A)$. Then $\exp(A) \leq n + s(n-2)$.

11. Let A be an $n \times n$ primitive $(0,1)$-matrix, $n \geq 2$. Then $\exp(A) \leq (n-1)^2 + 1$. Equality holds if and only if there exists a permutation matrix P such that

$$PAP^T = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 1 & 0 & 0 & \cdots & 1 \\ 1 & 0 & 0 & \cdots & 0 \end{pmatrix}.$$

12. The set Ω_n of $n \times n$ doubly stochastic matrices is a compact convex set.

13. *Birkhoff-von Neumann theorem*: Every $A \in \Omega_n$ can be expressed as a convex combination of $n \times n$ permutation matrices: namely, $A = c_1P_1 + c_2P_2 + \cdots + c_tP_t$ for some permutation matrices $P_1, P_2, \ldots, P_t$ and some positive real numbers $c_1, c_2, \ldots, c_t$ with $c_1 + c_2 + \cdots + c_t = 1$.

14. The following conditions are equivalent for an $n \times n$ matrix A:

- A has doubly stochastic pattern;
- There exist permutation matrices P, Q such that PAQ is a direct sum of fully indecomposable matrices;
- Every nonzero entry of A is contained in a positive diagonal.

15. Let A be an $n \times n$ nonnegative idempotent matrix of rank k. Then there exists a permutation matrix P such that

$$PAP^T = \begin{pmatrix} J & JU & 0 & 0 \\ 0 & 0 & 0 & 0 \\ VJ & VJU & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

where J is a direct sum of k positive idempotent matrices of rank 1, and where U and V are arbitrary nonnegative matrices of appropriate sizes.

16. A nonnegative symmetric matrix A of rank k is idempotent if and only if there exists a permutation matrix P such that

$$PAP^T = \begin{pmatrix} J & 0 \\ 0 & 0 \end{pmatrix},$$

where J is a direct sum of k positive symmetric rank one idempotent matrices.

17. Each completely positive $n \times n$ matrix is nonnegative, symmetric, and positive semidefinite. For $n \leq 4$ the converse is also true.

18. The set of $n \times n$ completely positive matrices is a closed convex cone and its extreme rays are generated by the rank one matrices xx^T where x is a nonnegative vector in $\mathcal{R}^n$.

19. A graph G is completely positive (meaning that every nonnegative positive semidefinite matrix with graph G is completely positive) if and only if G does not have an odd cycle of length greater than 4.

Examples:

1. The following nonnegative matrix is in Frobenius normal form

$$\left(\begin{array}{c|cc|cc|cc}
5 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
0 & 1 & 1 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 & 0 & 0 & 0 \\
\hline
2 & 4 & 1 & 0 & 3 & 0 & 0 \\
1 & 2 & 0 & 2 & 1 & 0 & 0 \\
\hline
0 & 1 & 1 & 0 & 0 & 3 & 2 \\
0 & 2 & 1 & 0 & 0 & 2 & 3
\end{array}\right)$$

with four classes $C_1 = \{1\}$, $C_2 = \{2,3\}$, $C_3 = \{4,5\}$ and $C_4 = \{6,7\}$. Class C_3 has access to C_1 and C_2 while class C_4 has access to C_2. Classes C_1 and C_2 are final, since they have access to no other classes. The eigenvalues of A are -2, -1, 1, 2, 3, 5, 5 so $\rho(A) = 5$. Classes C_1 and C_4 are basic since $\rho(A[C_1]) = \rho(A[C_4]) = 5$. Since no class has access to C_3, Fact 5 shows there is a nonnegative eigenvector of A for the eigenvalue $\rho(A[C_3]) = 3$, namely $(0,0,0,1,1,0,0)^T$. However there is no nonnegative eigenvector of A for $\rho(A[C_2]) = 2$ since class C_3 has access to class C_2 and $\rho(A[C_3]) \geq \rho(A[C_2])$.

2. The directed graph of the matrix

$$A = \begin{pmatrix} 0 & 1 & 7 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{pmatrix}$$

is the union of the cycles $1,2,5,1$ and $1,3,4,1$. The greatest common divisor of the lengths of all cycles passing through vertex 1 is 3, which by Fact 8 must be the index of cyclicity. In fact, A has eigenvalues 2, $-1 \pm i\sqrt{3}$, 0, 0 and thus there are 3 eigenvalues with modulus $\rho(A) = 2$.

3. By Fact 13 every doubly stochastic matrix is a convex combination of permutation matrices. For example, the doubly stochastic matrix

$$\begin{pmatrix} .4 & .3 & .3 & 0 \\ .5 & 0 & .4 & .1 \\ .1 & .6 & 0 & .3 \\ 0 & .1 & .3 & .6 \end{pmatrix}$$

can be expressed as

$$.2\begin{pmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} + .3\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} + .1\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} + .4\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

6.6.4 PERMANENTS

The permanent of a matrix is defined as a sum of terms, each corresponding to the product of elements along a diagonal of the matrix. Permanents arise in the study of systems of distinct representatives and in other combinatorial problems.

Definition:

The ***permanent*** of the $n \times n$ matrix A is $\text{per}(A) = \sum_{\sigma \in S_n} a_{1\sigma(1)} a_{2\sigma(2)} \ldots a_{n\sigma(n)}$, where S_n is the symmetric group on n elements. (See §5.3.1.)

Facts:

1. The permanent of A is an unsigned version of the determinant of A. (See §6.3.4, Fact 2.)

2. Computing the permanent of a square $(0,1)$-matrix is #P-complete.

3. *Laplace expansion*: Suppose A is an $n \times n$ matrix and A_{ij} is the submatrix of A obtained by deleting the ith row and the jth column. Then for $i = 1, 2, \ldots, n$

$$\text{per}(A) = \sum_{j=1}^{n} a_{ij} \ \text{per}(A_{ij}).$$

A similar expansion holds with respect to any column.

4. $\text{per}(A^T) = \text{per}(A)$.

5. Interchanging two rows (or two columns) of A does not change $\text{per}(A)$.

6. Multiplying any row (or column) of A by the scalar α multiplies $\text{per}(A)$ by α.

7. Unlike the determinant, the permanent is not multiplicative with respect to matrix multiplication. (See Example 2.)

8. The permanent of a triangular matrix (§6.3.1) is equal to the product of its diagonal entries.

9. The permanent of a block diagonal matrix is equal to the product of the permanents of its diagonal blocks.

10. For each positive integer n the permanent of the $n \times n$ matrix

$$\begin{pmatrix} 0 & 1 & \cdots & 1 \\ 1 & 0 & \cdots & 1 \\ \vdots & \vdots & & \vdots \\ 1 & 1 & \cdots & 0 \end{pmatrix}$$

is $n! \sum_{r=0}^{n} (-1)^r \frac{1}{r!}$ and it represents the number of derangements (§2.4.2) of order n.

11. The permanent of an $n \times n$ $(0,1)$-matrix A counts the number of assignments ($n \times n$ permutation submatrices) consistent with the 1 entries of A.

12. *Minc-Bŕegman inequality*: Let A be an $n \times n$ $(0,1)$-matrix with row sums $r_1, r_2, \ldots,$ r_n. Then

$$\text{per}(A) \le \prod_{i=1}^{n} (r_i!)^{1/r_i}.$$

13. If A is a nonnegative $n \times n$ matrix with row sums $r_1, r_2, \ldots, r_n$ then $\text{per}(A) \le r_1 r_2 \ldots r_n$.

14. Let A be a fully indecomposable nonnegative integral $n \times n$ matrix and let $s(A)$ denote the sum of the entries in A. Then

$$s(A) - 2n + 2 \leq \operatorname{per}(A) \leq 2^{s(A)-2n} + 1.$$

15. *Alexandroff inequality*: Let A be a nonnegative $n \times n$ matrix and let A_i be the ith column of A, $i = 1, 2, \ldots, n$. Then

$$(\operatorname{per}(A))^2 \geq \operatorname{per}(A_1, \ldots, A_{n-2}, A_{n-1}, A_{n-1}) \operatorname{per}(A_1, \ldots, A_{n-2}, A_n, A_n).$$

16. The definition of the permanent can be extended to $m \times n$ matrices with $m \leq n$ by summing over all permutations in S_m.

17. If A is an $m \times n$ $(0,1)$-matrix, then $\operatorname{per}(A) > 0$ if and only if A has term rank m.

18. *van der Waerden-Egorychev-Falikman inequality*: If A is a doubly stochastic $n \times n$ matrix then $\operatorname{per}(A) \geq \frac{n!}{n^n}$, and equality holds if and only if $A = J_n$, the matrix with each entry $\frac{1}{n}$.

Note: This result was first conjectured by B. L. van der Waerden in 1926. Despite repeated attempts to prove it, the conjecture remained unresolved until finally established in 1980 by G. P. Egorychev. The conjecture was also proved independently by D. I. Falikman in 1981, apart from establishing the uniqueness of the minimizing matrix A. A self-contained exposition of Egorychev's proof is given in [Kn81].

19. Let A be the $m \times n$ incidence matrix of m subsets of a given n-set X: namely, $a_{ij} = 1$ if $j \in X_i$ and $a_{ij} = 0$ otherwise. Then $\operatorname{per}(A)$ counts the number of SDRs (systems of distinct representatives, §1.2.2) selected from the sets $X_1, X_2, \ldots, X_m$.

Examples:

1. For the matrix

$$A = \begin{pmatrix} 1 & 0 & 2 \\ 3 & 1 & 1 \\ 1 & 5 & 2 \end{pmatrix},$$

evaluation of $\operatorname{per}(A)$ by the definition gives $\operatorname{per}(A) = 1\cdot1\cdot2 + 2\cdot3\cdot5 + 2\cdot1\cdot1 + 1\cdot1\cdot5 = 39$. Using the Laplace expansion on row 1 gives $\operatorname{per}(A) = 1 \cdot \operatorname{per}\begin{pmatrix} 1 & 1 \\ 5 & 2 \end{pmatrix} + 2 \cdot \operatorname{per}\begin{pmatrix} 3 & 1 \\ 1 & 5 \end{pmatrix} = 1 \cdot 7 + 2 \cdot 16 = 39$.

2. If $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, then $C = AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$. Notice that $\operatorname{per}(AB) = 3 \neq 1 \cdot 1 = \operatorname{per}(A)\operatorname{per}(B)$.

3. *Assignments*: Suppose there are 4 applicants for 4 jobs, where the qualifications of each applicant i for each job j can be specified by the $(0,1)$-matrix

$$A = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}.$$

Then the number of different assignments of jobs to qualified applicants (see §6.6.1, Example 3) equals $\operatorname{per}(A) = 4$. In fact, these are given by those permutations σ where $\{(\sigma(1), \sigma(2), \sigma(3), \sigma(4))\} = \{(2,1,4,3), (2,4,3,1), (4,1,3,2), (4,2,3,1)\}$.

4. *Ménage problem*: Suppose that 5 wives are seated around a circular table, leaving one vacant space between consecutive women. Find the number of ways to seat in these vacant spots their 5 husbands so that no man is seated next to his wife. Suppose that the wives occupy positions $W_1, W_2, \ldots, W_5$ listed in a clockwise fashion around the table and that X_i is the vacant position to the right of W_i. Let A be the 5×5 $(0,1)$-matrix where $a_{ij} = 1$ if and only if husband H_i can be assigned to position X_i without violating the requirements of the problem. Then

$$A = \begin{pmatrix} 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \end{pmatrix}.$$

By Fact 11, the number of possible assignments for each fixed placement of wives is $\text{per}(A) = 13$. (Also see §2.4.2, Example 7.)

5. Count the number of nontaking rooks on a chessboard with restricted positions (§2.4.2). Specifically, suppose that positions $(1,1), (2,3), (3,1), (4,2), (4,3)$ of a 4×4 chessboard cannot be occupied by rooks. In the remaining positions, 4 rooks are to be placed so they are nontaking: no two are in the same row or in the same column. This can be solved (see Fact 11) by finding all permutations consistent with the 1s in the matrix

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 \end{pmatrix}.$$

Here $\text{per}(A) = 6$ is easily found using the Laplace expansion on the first column of A, so there are 6 placements of nontaking rooks.

6.6.5 MATRIX COMPLETION AND SIGN-SOLVABILITY

Matrix completion deals with filling in missing entries in a partial matrix to obtain a matrix with certain properties. Applications of this concept can be found in data analysis and control, for example. The linear algebra of sign-solvability is motivated by qualitative analysis in economics.

Definitions:

A real symmetric $n \times n$ matrix A is called ***positive semidefinite*** if $x^T Ax \geq 0$ for all $x \in \mathcal{R}^n$, i.e., the quadratic form $Q(x) = x^T Ax = \sum_{i,j} a_{ij} x_i x_j$ is never negative.

A real symmetric $n \times n$ matrix A is called ***copositive*** if $x^T Ax \geq 0$ for all nonnegative $x \in \mathcal{R}^n$.

A ***partial matrix*** is a rectangular array in which some entries are specified and others are not. If values are chosen for each unspecified entry, one obtains a ***completion*** of the partial matrix.

The ***sign pattern*** of a matrix A is the matrix obtained from A by replacing each entry by its sign (0, 1, or -1). The ***qualitative class*** $\mathcal{Q}(A)$ of A consists of all matrices with the same sign pattern as A.

A system of linear equations $Ax = b$ is ***sign-solvable*** if for each $\tilde{A} \in \mathcal{Q}(A)$ and $\tilde{b} \in \mathcal{Q}(b)$, the system $\tilde{A}x = \tilde{b}$ has a solution and all solutions obtained in this way lie in the same qualitative class. Thus, changing numerical values, but not the sign, of the data in the linear system does not change the sign of the solutions.

Matrix A is termed an ***L-matrix*** if every matrix in the qualitative class of A has linearly independent rows. A square L-matrix is called a ***sign-nonsingular*** (***SNS***) ***matrix***.

Facts:

1. The set of $n \times n$ copositive matrices is a convex cone which is the dual of the cone of $n \times n$ completely positive matrices.

2. Let A be a partial matrix whose fully specified principal submatrices are positive semidefinite, and with positive diagonal elements. Then A can be completed to a positive semidefinite matrix if and only the graph of A (corresponding to specified entries) is chordal, i.e., every cycle of length at least 4 has a chord.

3. Every partial copositive matrix has a completion that is copositive.

4. The linear system $Ax = 0$ is sign-solvable if and only A^T is an L-matrix.

5. If the linear system $Ax = b$ is sign-solvable, then A^T is an L-matrix.

6. A matrix A is an L-matrix if and only if for every diagonal matrix D with diagonal elements $0, \pm 1$ the matrix DA contains a nonzero column which is unisigned (i.e., it does not contain both a positive and a negative entry).

7. The recognition problem for L-matrices is NP-complete.

8. A square matrix A is an SNS-matrix if and only if $\det A \neq 0$ and the determinant of every matrix in $\mathcal{Q}(A)$ has the same sign.

9. $Ax = b$ is sign-solvable if and only if A is an SNS-matrix and each matrix obtained from A by replacing a column by b is either an SNS-matrix or has an identically zero determinant (that is, each of the $n!$ terms in the determinant expression is zero).

Examples:

1. The following matrix A is a partial copositive matrix and B is a copositive completion of A.

$$A = \begin{pmatrix} 8 & ? & -1 \\ ? & 2 & -1 \\ -1 & -1 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 8 & 4 & -1 \\ 4 & 2 & -1 \\ -1 & -1 & 1 \end{pmatrix}.$$

2. The linear system $Ax = b$ whose sign patterns are

$$A' = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \quad b' = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

is sign-solvable. The determinant of every matrix in $\mathcal{Q}(A)$ is negative, so A is an SNS-matrix. Moreover, when $\tilde{A} \in \mathcal{Q}(A)$ and $\tilde{b} \in \mathcal{Q}(b)$, every solution $x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$ of $\tilde{A}x = \tilde{b}$ satisfies that x_1 and x_2 have the same sign (by the second equation) and actually $x_1, x_2 > 0$ (by the first equation). The notion of sign-solvability is motivated by qualitative problems in economics; see [BrSh09] and [Sa83].

3. A matrix A whose sign pattern is

$$A' = \begin{pmatrix} 1 & 0 & 0 & * \\ 0 & -1 & 0 & * \\ 0 & 0 & 1 & * \end{pmatrix}$$

where $*$ denotes any sign, is an L-matrix. This is seen from the definition or by Fact 6.

6.7 SINGULAR VALUE DECOMPOSITION

The singular value decomposition (SVD) is a matrix factorization that is used widely in many applications. Its importance in data analysis as well as in theory has changed the field of linear algebra over the last three decades. In recent years, the SVD and higher-order equivalents have become even more prominent due to increased computational memory and speed, as well as the multidimensional nature of many datasets.

6.7.1 BASIC CONCEPTS

Definitions:

A ***singular value decomposition*** (***SVD***) of a matrix $A \in \mathcal{R}^{m\times n}$ expresses $A = U\Sigma V^T$, where $U \in \mathcal{R}^{m\times m}$, $V \in \mathcal{R}^{n\times n}$ are orthogonal matrices and $\Sigma \in \mathcal{R}^{m\times n}$ is diagonal. The diagonal entries σ_i of Σ also satisfy $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_p \geq 0$, where $p = \min(m, n)$.

The ***singular values*** of A are the diagonal entries of Σ.

The ***left singular vectors*** of A are the $m \times 1$ column vectors of U.

The ***right singular vectors*** of A are the $n \times 1$ column vectors of V.

If the SVD of an $m \times n$ matrix A is given by $A = U\Sigma V^T$ then the ***thin*** (***or reduced***) ***SVD*** of A ($m \geq n$) expresses $A = U_1\Sigma_1 V^T$, where U_1 is $m \times n$ and contains the first n columns of U and Σ_1 is an $n \times n$ diagonal matrix containing the n singular values of A.

The ***matrix p-norm*** for $1 \leq p \leq \infty$ of a matrix $A \in \mathcal{R}^{m\times n}$ corresponding to the vector p-norm is the real number

$$||A||_p = \sup\left\{\tfrac{||Ax||_p}{||x||_p} \mid x \neq 0,\, x \in \mathcal{R}^n\right\}.$$

The ***Frobenius norm*** of a matrix $A \in \mathcal{R}^{m\times n}$, denoted $||A||_F$, is the real number

$$||A||_F = \sqrt{\textstyle\sum_{i=1}^m \sum_{j=1}^n |a_{ij}|^2}.$$

Facts:

Most of these facts can be found in an advanced linear algebra or matrix theory book. See [GoVL13, §2.4], [Ma13], [TrBa97, Lectures 4–5] for more details and proofs.

1. Any $m\times n$ matrix A has an SVD factorization. If $A \in \mathcal{C}^{m\times n}$ then the SVD is written as $A = U\Sigma V^*$, where U and V are unitary, but $\Sigma \in \mathcal{R}^{m\times n}$.

2. The singular values of A are uniquely determined.

3. If A is square and the singular values are distinct, then the left and right singular vectors are uniquely determined up to (complex) signs.

4. Suppose $A = U\Sigma V^T$ is the SVD of A and there are r nonzero singular values. Denote u_i as the ith column of U and v_j as the jth column of V. Then

- $\text{rank}(A) = r$;
- $\text{null}(A) = \text{span}\{v_{r+1}, \ldots, v_n\}$;
- $\text{range}(A) = \text{span}\{u_1, \ldots, u_r\}$;
- $\text{null}(A^T) = \text{span}\{u_{r+1}, \ldots, u_m\}$;
- $\text{range}(A^T) = \text{span}\{v_1, \ldots, v_r\}$.

5. If the SVD of A is given by $A = U\Sigma V^T$ then

- the nonzero singular values of A are the square roots of the nonzero eigenvalues of both AA^T and A^TA;
- the columns of U are the orthonormal eigenvectors of AA^T;
- the columns of V are the orthonormal eigenvectors of A^TA.

6. If A is symmetric then the singular values of A are the absolute values of the eigenvalues of A.

7. The image of the unit sphere in $\mathcal{R}^n$ under the map $A = U\Sigma V^T$ is a hyperellipse in $\mathcal{R}^m$. The nonzero singular values are the lengths of the principal semi-axes of the hyperellipse and the left singular vectors are the unit vectors in the direction of the principal semi-axes.

8. The SVD can be written as a sum of rank-1 matrices:

$$A = \sum_{i=1}^{r} \sigma_i u_i v_i^T, \tag{1}$$

where $r = \text{rank}(A)$, σ_i is the ith singular value, and u_i, v_i are the ith left and right singular vectors, respectively.

9. If A is $m \times n$ and has nonzero singular values $\sigma_1, \ldots, \sigma_r$ then

- $||A||_2 = \sigma_1$;
- $||A||_F = \sqrt{\sigma_1^2 + \sigma_2^2 + \cdots + \sigma_r^2}$;
- $\displaystyle\min_{x \neq 0} \frac{||Ax||_2}{||x||_2} = \sigma_n$ if $m \geq n$.

10. If $k < r = \text{rank}(A)$ and $A_k = \displaystyle\sum_{i=1}^{k} \sigma_i u_i v_i^T$ then

- $\displaystyle\min_{\text{rank}(B)=k} ||A - B||_2 = ||A - A_k||_2 = \sigma_{k+1}$;
- $\displaystyle\min_{\text{rank}(B)=k} ||A - B||_F = ||A - A_k||_F = \sqrt{\sigma_{k+1}^2 + \cdots + \sigma_r^2}$.

11. If A is an $n \times n$ square matrix then $|\det(A)| = \displaystyle\prod_{i=1}^{n} \sigma_i$.

12. If A is square then it can be factored into its *polar decomposition* $A = QP$, where Q is orthogonal and P is symmetric and positive definite. If $A = U\Sigma V^T$ is the SVD of A then the polar decomposition of A is given exactly by $A = (UV^T)(V\Sigma V^T)$.

Examples:

1. Let $A = \begin{bmatrix} 3 & 2 \\ 2 & 3 \\ 2 & -2 \end{bmatrix}$. The SVD of $A = U\Sigma V^T$ is

$$U = \begin{bmatrix} -\sqrt{2}/2 & 1/\sqrt{18} & -2/3 \\ -\sqrt{2}/2 & -1/\sqrt{18} & 2/3 \\ 0 & 4/\sqrt{18} & 1/3 \end{bmatrix}, \; V = \begin{bmatrix} -\sqrt{2}/2 & \sqrt{2}/2 \\ -\sqrt{2}/2 & -\sqrt{2}/2 \end{bmatrix}, \; \Sigma = \begin{bmatrix} 5 & 0 \\ 0 & 3 \\ 0 & 0 \end{bmatrix}.$$

- $\text{rank}(A) = 2$ since there are two nonzero singular values.
- $||A||_2 = 5$ and $||A||_F = \sqrt{5^2 + 3^2} = \sqrt{34}$.
- A can be written as a sum of two rank-1 (outer product) matrices:

$$A = 5 \begin{bmatrix} -\sqrt{2}/2 \\ -\sqrt{2}/2 \\ 0 \end{bmatrix} \begin{bmatrix} -\sqrt{2}/2 \\ -\sqrt{2}/2 \end{bmatrix}^T + 3 \begin{bmatrix} 1/\sqrt{18} \\ -1/\sqrt{18} \\ 4/\sqrt{18} \end{bmatrix} \begin{bmatrix} \sqrt{2}/2 \\ -\sqrt{2}/2 \end{bmatrix}^T.$$

- The eigenvalues of A^TA are $\lambda_1 = 25$ and $\lambda_2 = 9$, which are the squares of the singular values.

2. Let $A = \begin{bmatrix} -1 & 2 & 2 \\ 2 & -1 & 2 \\ 2 & 2 & -1 \end{bmatrix}$. The singular values of A are $\sigma_1 = 3, \sigma_2 = 3, \sigma_3 = 3$. Thus the determinant is the product of the singular values: $\det(A) = 27$.

6.7.2 COMPUTATION OF THE SVD

Mathematically, the SVD of A can be computed using the eigenvalue decomposition of A^TA. This algorithm is not preferred in practice for two reasons. First, the algorithm is numerically unstable since forming A^TA can result in a loss of information [GoVL13, §5.3.2]. Second, if A is large, forming A^TA may be troublesome. Even if A^TA can be formed, computing its eigenvalue decomposition may be impractical. In practice, the main SVD algorithm is iterative and similar to the QR algorithm used to compute eigenvalues (§6.5.4) without explicit formation of A^TA. Here we present an overview of the common SVD algorithms and refer to [GoVL13], [ClDh13] for details and references.

Definitions:

A ***Householder matrix*** is an $m \times m$ matrix P such that

$$P = I - \beta vv^T, \qquad \beta = \tfrac{2}{v^Tv},$$

where $v \in \mathcal{R}^m$ is nonzero. A Householder matrix represents a linear transformation that reflects a vector in the hyperplane $\text{span}\{v\}^{\perp}$.

An upper (lower) ***bidiagonal*** matrix $B = (b_{ij})$ is a matrix in which the only nonzero b_{ij} occur when $i = j$ or $i = j - 1$ ($i = j + 1$).

Facts:

1. *SVD with Golub-Kahan bidiagonalization:* This method (Algorithm 1) computes the SVD of a matrix A using a two-phase approach; a bidiagonalization phase followed by an iterative procedure to diagonalize the bidiagonal matrix.

Algorithm 1: **SVD with Golub-Kahan bidiagonalization.**

```
input: $m \times n$ matrix $A$, $m \geq n$
output: matrices $U, V, \Sigma$ such that $A = U\Sigma V^T$ gives the SVD of $A$.

1. bidiagonalization. $A$ is brought to upper bidiagonal form (see [GoKa65])

{Initialization}
$A_1 := A$
{Iterative step}
for $k := 1$ to $n$
  $A_{k+1} := U_k^T A_k$
  if $k \leq n - 2$
    $A_{k+1} := A_{k+1} V_k$
$B := A_{n+1}$
$\tilde{U}_1 := U_1 U_2 \cdots U_n$
$\tilde{V}_1 := V_1 V_2 \cdots V_{n-2}$

2. diagonalization. Upper bidiagonal $B = \tilde{U}_1^T A \tilde{V}_1$ is diagonalized using a variant of the QR algorithm (see [GoVL13, §8.6.3])

{Iterative step}
for $k := 1$ to $n - 1$
  $B := BV_k(\theta_1; k, k+1)$
  $B := U_k(\theta_2; k, k+1)^T B$
$\tilde{U}_2 := U_1 U_2 \cdots U_{n-1}$
$\tilde{V}_2 := V_1 V_2 \cdots V_{n-1}$
$U := \tilde{U}_1 \tilde{U}_2$
$V := \tilde{V}_1 \tilde{V}_2$
$\Sigma := B$
```

2. The bidiagonalization step of Algorithm 1 finds $\tilde{U}_1$ and $\tilde{V}_1$ simultaneously by *implicitly* applying the QR method for the symmetric eigenvalue problem to $A^T A$ [GoVL13, §8.6.3].

3. In the bidiagonalization step of Algorithm 1, the orthogonal matrix U_k is a Householder matrix that reflects the vector $A_k([k, k+1, \ldots, n], k)$ onto a multiple of e_1. Similarly, the orthogonal matrix V_k is a Householder matrix that reflects the vector $A_k(k, [k+1, k+2, \ldots, n])$ onto a multiple of e_1.

4. In the diagonalization step of Algorithm 1, the orthogonal matrix $V_k(\theta_1; k, k+1)$ is a rotation matrix defined by θ_1 such that

$$y^T V_k(\theta_1; k, k+1) = \alpha \begin{bmatrix} 1 & 0 \end{bmatrix},$$

where $\alpha \in \mathcal{R}$ and

$$y^T = \begin{cases} \begin{bmatrix} t_{11} - \lambda & t_{12} \end{bmatrix} & \text{for } k = 1 \\ \begin{bmatrix} b_{k,k+1} & b_{k,k+2} \end{bmatrix} & \text{for } 1 < k < n-1. \end{cases}$$

In the above, λ is the eigenvalue of the trailing 2×2 submatrix of T that is closest to t_{nn} for $T = B^T B$.

5. In the diagonalization step of Algorithm 1, the orthogonal matrix $U_k(\theta_2; k, k+1)$ is a rotation matrix defined by θ_2 such that

$$U_k(\theta_2; k, k+1)^T \begin{bmatrix} b_{kk} \\ b_{k+1,k} \end{bmatrix} = \beta \begin{bmatrix} 1 \\ 0 \end{bmatrix},$$

where $\beta \in \mathcal{R}$.

6. Various improvements to the bidiagonalization step have been proposed and there is a long history of work related to improving SVD algorithms in general. Specialized SVD algorithms for structured matrices have also been developed [GoVL13, §8.6], [ClDh13].

7. *Two-Sided Jacobi SVD:* This method (Algorithm 2) computes the SVD of a matrix by computing the SVD of 2×2 submatrices.

Algorithm 2: **Two-Sided Jacobi SVD.**

```
input: $m \times n$ matrix $A$
output: matrices $U, V, \Sigma$ such that $A = U\Sigma V^T$ gives the SVD of $A$.

{Initialization}
$A_1 = (a_{ij}^{(1)}) := A$
{Iterative step}
for $k := 1$ to ... until convergence criteria met
    choose $r, s$ $(r < s)$ with $|a_{rs}^{(k)}|$ as large as possible
    define $\phi$ by $\tan\phi = \dfrac{a_{rs}^{(k)} - a_{sr}^{(k)}}{a_{rr}^{(k)} + a_{ss}^{(k)}}$
    $B = (b_{ij}) := Q_k(\phi; r, s)^T A_k$
    define $\theta$ by $\cot 2\theta = \dfrac{b_{rr} - b_{ss}}{2b_{rs}}$
    $A_{k+1} = (a_{ij}^{(k+1)}) := J_k(\theta; r, s)^T B J_k(\theta; r, s)$
$\Sigma := A_{k+1}$
$U := Q_1 J_1 Q_2 J_2 \cdots Q_k J_k$
$V := J_1 J_2 \cdots J_k$
```

8. The sequence A_k in Algorithm 2 converges to a matrix with maximum sums of squares of its diagonal elements. Choosing the largest $|a_{rs}|$ works to ensure linear convergence so that the sums of squares of the off-diagonal elements decrease at each step. However, in practice the asymptotic convergence rate of Algorithm 2 is quadratic [GoVL13, §8.5]. The convergence criteria is met when the sums of squares of the off-diagonals are less than some prescribed tolerance.

9. The orthogonal matrix $Q(\phi; r, s)$ in Algorithm 2 represents a rotation by the angle ϕ, chosen so that the 2×2 (r, s) submatrix of $B = Q(\phi; r, s)A_k$ is symmetric.

10. The orthogonal matrix $J(\theta; r, s)$ in Algorithm 2 is the same as $U(\theta; r, s)$ in Algorithm 3 of §6.5.4, since the 2×2 (r, s) submatrix of B in the Two-Sided Jacobi Algorithm is symmetric.

6.7.3 SOLVING LINEAR SYSTEMS

The SVD is ubiquitous in real-world problems. Its widespread appeal is due to its stability in computation and ability to provide meaningful solutions of linear systems that may be ill-conditioned (i.e., close to singular). The SVD is the factorization of choice used to find the best solution to a non-square linear system or systems that are not full rank. It is also the most precise and numerically stable method to compute the rank of a matrix.

Definitions:

A ***rank-deficient*** matrix $A \in \mathcal{R}^{m\times n}$ has $\text{rank}(A) < \min(m, n)$.

An ***underdetermined*** system of linear equations is a system $Ax = b$, with $A \in \mathcal{R}^{m\times n}$, $x \in \mathcal{R}^n$, $b \in \mathcal{R}^m$, where $m < n$.

An ***overdetermined*** system of linear equations is a system $Ax = b$, with $A \in \mathcal{R}^{m\times n}$, $x \in \mathcal{R}^n$, $b \in \mathcal{R}^m$, where $m > n$.

A ***least squares*** problem finds a minimum norm solution to an overdetermined system of linear equations. That is, given $A \in \mathcal{R}^{m\times n}$, $b \in \mathcal{R}^m$, with $m > n$, solve

$$\min_{x\in\mathcal{R}^n} ||Ax - b||_2.$$

The ***Moore-Penrose pseudo-inverse*** of $A \in \mathcal{R}^{m\times n}$ is the unique matrix $A^+ \in \mathcal{R}^{n\times m}$ that satisfies

$$\begin{array}{rclcrcl} AA^+A & = & A, & \qquad & A^+AA^+ & = & A^+, \\ (AA^+)^T & = & AA^+, & & (A^+A)^T & = & A^+A. \end{array}$$

The ***numerical rank*** of a matrix $A \in \mathcal{R}^{m\times n}$ for some (small) tolerance δ is the number $\hat{r}$ such that the computed singular values (σ_i) of A satisfy

$$\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_{\hat{r}} > \delta > \sigma_{\hat{r}+1} \geq \cdots \geq \sigma_p, \qquad p = \min(m, n).$$

Usually $\delta = \epsilon||A||_\infty$ where ϵ is the machine epsilon.

Facts:

1. The most precise and numerically stable method to compute the rank of a matrix is to compute its numerical rank using the SVD.

2. Let the SVD of $A \in \mathcal{R}^{m\times n}$ be given by $A = U\Sigma V^T$, where $r = \text{rank}(A)$, σ_i is the ith singular value, u_i and v_i are the ith left and right singular vectors, respectively.

- The least squares solution $\tilde{x}$ to the overdetermined system $Ax = b$ is

$$\tilde{x} = \sum_{i=1}^{r} \frac{u_i^T b}{\sigma_i} v_i.$$

- The smallest 2-norm residual is given by

$$||A\tilde{x} - b||_2^2 = \textstyle\sum_{i=r+1}^{m} (u_i^T b)^2.$$

- The smallest 2-norm solution above is also valid if the system is underdetermined.

3. The Moore-Penrose pseudo-inverse $A^+ \in \mathcal{R}^{n\times m}$ of $A \in \mathcal{R}^{m\times n}$ is computed using the SVD of A. Specifically, if $A = U\Sigma V^T$ is the SVD of A, then $A^+ = V\Sigma^+ U^T$ where $\Sigma^+ \in \mathcal{R}^{n\times m}$ has diagonal elements $1/\sigma_i$ for $i = 1, \ldots, r$ followed by $n - r$ zeros ($r = \text{rank}(A)$).

- The least squares solution $\tilde{x}$ to the overdetermined system $Ax = b$ can also be written as $\tilde{x} = A^+ b$.
- The pseudo-inverse $A^+ \in \mathcal{R}^{n\times m}$ of $A \in \mathcal{R}^{m\times n}$ is the unique Frobenius norm solution to the problem

$$\min_{X\in\mathcal{R}^{n\times m}} ||AX - I_m||_F.$$

- If A is square and nonsingular, then $A^+ = A^{-1}$.

Examples:

1. Suppose $A = \begin{bmatrix} 3 & 2 \\ 2 & 3 \\ 2 & -2 \end{bmatrix}$ and $b = \begin{bmatrix} 1 \\ 2 \\ 2 \end{bmatrix}$.

- The Moore-Penrose pseudo-inverse of A is $A^+ = \frac{1}{45}\begin{bmatrix} 7 & 2 & 10 \\ 2 & 7 & -10 \end{bmatrix}$.
- The least squares solution to $Ax = b$ is $\tilde{x} = A^+ b = \frac{1}{45}\begin{bmatrix} 31 \\ -4 \end{bmatrix}$.

2. Note that $(AB)^+ \neq B^+ A^+$ in general, even if A, B are square. For example, let

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$

Then $(AB)^+ = \begin{bmatrix} \frac{1}{2} & 0 \\ \frac{1}{2} & 0 \end{bmatrix}$; however $B^+ A^+ = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$.

6.7.4 APPLICATIONS

The SVD is utilized in many applications. It plays a major role in statistics where it is used in Principal Component Analysis and multivariate data analysis. Here we list some main application areas of the SVD with the understanding that the list is not exhaustive, but rather it gives a flavor for the types of problems that are well suited for the SVD.

Definitions:

Dimension reduction is a method that reduces the number of dimensions of a dataset while maintaining as much information about the dataset as possible.

Let $A \in \mathcal{R}^{m\times n}$ comprise a matrix whose ith column represents m measurements of the ith variable centered about zero. Then $\frac{1}{m-1}A^T A$ is a ***covariance matrix***, in which the (i, j)-element measures the covariance between column i and column j of A.

Alternating least squares (***ALS***) is a method that solves a multidimensional least squares problem such that holding all variables constant but one reduces the problem to a linear least squares problem (§6.7.3) in that one variable. The multidimensional problem is solved by alternating which set of variables is held constant with the goal to eventually converge to the multidimensional least squares solution, though convergence is not guaranteed.

Examples:

1. *Principal Component Analysis* (PCA): PCA is a dimension reduction technique that performs an orthogonal transformation of a dataset $A \in \mathcal{R}^{m\times n}$ in order to reduce its dimensionality while retaining as much of the variation as possible [Jo02]. PCA computes the eigenvalue decomposition of the covariance matrix of A. The eigenvectors (*principal components*) corresponding to the dominant eigenvalues contain most of the variation of the data and are uncorrelated. PCA is equivalent to computing the SVD of the data matrix due to Fact 5, §6.7.1.

2. *Latent Semantic Indexing* (LSI): Given a set of n documents and a set of m terms appearing in those documents, set A to be the $m \times n$ *term-document matrix* where the (i, j)-element of A is the number of times term i appears in document j. LSI uses the SVD of A in order to correlate related terms in a set of documents [De88], [BeDuOB95], [Me00, §5.12]. This is often used to find relevant documents based on a user query of a set of terms. Due to the typically large size of A in real-world applications, Fact 10 in Section §6.7.1 is used to compute the nearest rank-k approximation to A where $k << \text{rank}(A)$.

3. *Eigenfaces:* Given a set of N grayscaled facial images all of size $m \times n$, set A to be the $mn \times N$ matrix where the jth column is the vectorized matrix of pixels of image j. Eigenfaces is a facial recognition algorithm that uses PCA to project an $m \times n$ query image onto the dominant eigenspaces of the covariance matrix of A. This is equivalent to computing the SVD of A. See [MuMaHe04], [TuPe91a], [TuPe91b] for more information.

4. *Collaborative Filtering:* Collaborative filtering is one approach to a class of methods called *recommender systems* that work to give suggestions on an item i to a user u. Recommender systems have become extremely popular recently due to their substantial improvement to the Netflix recommender system publicized by the winner of the Netflix prize [KoBeVo09]. They are now in use in many internet sites, including Amazon.com, YouTube, Netflix, Yahoo, and more. Collaborative filtering is used when explicit feedback of user ratings towards items is not available and user behavior ("click history") is used instead.

Suppose A is the $m \times n$ user-item matrix where the (u, i)-entry is a rating r_{ui} which indicates the preference by user u of item i (we use the r_{ui} terminology to remain consistent with the collaborative filtering literature). The general model is based on the SVD and in its most basic form involves finding (not necessarily orthogonal) matrices X, Y that solve

$$\min\{||A^T - Y^T X||_2^2 \mid X \in \mathcal{R}^{k\times m},\ Y \in \mathcal{R}^{k\times n}\},$$

where $k << \text{rank}(A)$. There are many extensions to this basic model, including regularization and addition of bias terms. Since A is typically very large, the SVD cannot be explicitly computed and ALS is used instead to find the best X, Y. The ith column of Y measures the extent to which item i possesses the k factors, and the uth column of X measures the extent of interest user u has in items high in the k factors. Therefore, r_{ui} is viewed as an inner product of column i of Y and column u of X. See [KoBe11] for a detailed treatment of collaborative filtering.

5. *Data Mining:* The SVD is used in a variety of problems related to clustering and multivariate analysis of large datasets (see for example [MaKeHo05]). PCA, LSI, and

Eigenfaces are three examples of data mining techniques, but there are more. The SVD is also used in graph partitioning for the ratio cut problem and is used in the HITS Algorithm for web searching and queries [Kl99]. The SVD appears in chemical physics to obtain approximate solutions to the coupled-cluster equations and is a popular tool for electronic structure calculations [Ki03]. It is useful in genetics in a PCA context to understand the dynamics of gene expression and classify genes into groups of similar regulation and function [AlBrBo00], [HoEtal00]. The SVD has found its way into political science where it was used to investigate the ideologies of members of Congress [MaPo12], [PoEtal05], [PoEtal07]. It has also been applied in robotics [BeKu02], financial mathematics [FeEtal11], compressed sensing [XuLi10], and geophysics [Sm94].

6. *Cross-Modal Factor Analysis* (CFA): CFA is a technique to rotate both optimally and rigidly one m-element data matrix into another. The rotation is rigid in the sense that both distances and angles between the elements in the initial data matrix are preserved. The rotation is optimal in the sense that the sum of the m squared (Euclidean) distances between the corresponding initial and target data point pairs is minimized. CFA is also known as the *orthogonal Procrustes problem* [GoVL13]. In particular, to map an $m \times n$ data matrix B optimally into an $m \times n$ data matrix A solve

$$\min_{Q \in \mathcal{R}^{n \times n}} ||A - BQ||_F^2, \qquad \text{subject to } Q^T Q = I_n.$$

The optimal Q is $Q = UV^T$ where U, V are found from the SVD $B^T A = U \Sigma V^T$. Note that if B is an $m \times n$ data matrix and $A = BQ$ for some unknown orthogonal transformation Q, then the minimum squared Frobenius norm is 0 and CFA may be applied to recover the matrix Q.

7. *Canonical Correlation Analysis* (CCA): CCA is a way of measuring correlations between two groups of random variables, $x = (x_1, \ldots, x_m)$ and $y = (y_1, \ldots, y_n)$ [Ho36], [Mu82], [BjGo73]. The goal is to find linear combinations of the first group and linear combinations of the second group that are maximally correlated. The solution is found using the SVD of the *cross-covariance matrix*, in which the (i, j)-element is the covariance between variables x_i and y_j.

8. *Geometric Applications:* Fact 7, §6.7.1 is used in geology to measure the grain sizes of irregularly shaped crystals. This is done by finding ellipsoids that approximate the size and shape of each grain [MaPo12], [Hi06], [Ma98]. The SVD is also used in shape matching problems; see for example [RuGa06].

9. *Compression:* The SVD is used in many areas to obtain low-rank approximations to a dataset using Fact 10, §6.7.1. It is used in signal processing as a noise reduction method, where a low-rank approximation represents a filtered signal with less noise [Me00, §5.12]. Using the SVD as a noise filter is also popular in image deblurring [HaNaOL06]. Similarly, the SVD is used in image processing to obtain a low-rank approximation to an image as a way to compress the image signal [Ka96].

10. *Other Applications:* The SVD is used in entanglement, a quantum form of correlation, where it is used to diagonalize the one-particle reduced density matrix to obtain the natural orbitals (i.e., the singular vectors) and their occupation numbers (i.e., the singular values) [PaYo01], [ScLoMa01], [MaPo12]. It is also important for theoretical endeavors, such as path-following methods for computing curves of equilibria in dynamical systems [DiGaPa06].

6.7.5 Higher Dimensions

More and more applications involve data that are best represented in higher dimensions. In particular, data compression and PCA are two significant motivating areas that have prompted higher-dimensional equivalents of the matrix SVD. Thus, information is stored in multidimensional (or multiway) arrays, i.e., tensors, instead of as matrices. Nearly all the fields mentioned in §6.7.4 and many others use higher-order tensors for multidimensional data analysis.

Definitions:

An ***order-N tensor*** is a multiway array with N indices:

$$\mathcal{A} = (a_{i_1 i_2 \ldots i_N}) \in \mathcal{R}^{I_1 \times I_2 \times \cdots \times I_N}.$$

The ***outer product***, denoted by "$\circ$," of a set of N vectors $x_1 \in \mathcal{R}^{I_1}, x_2 \in \mathcal{R}^{I_2}, \ldots, x_N \in \mathcal{R}^{I_N}$ is the order-N tensor

$$\mathcal{A} = x_1 \circ x_2 \circ \cdots \circ x_N \in \mathcal{R}^{I_1 \times I_2 \times \cdots \times I_N},$$

where each element $a_{i_1 i_2 \ldots i_N}$ of $\mathcal{A}$ is the product of the corresponding vector elements:

$$a_{i_1 i_2 \ldots i_N} = x_1(i_1) x_2(i_2) \ldots x_N(i_N) \qquad \text{for all } 1 \le i_j \le I_j.$$

Here $x_j(i_j)$ refers to the i_jth element of the vector x_j for $j = 1, \ldots, N$.

If an order-N tensor $\mathcal{A}$ can be expressed as an outer product of N vectors, then $\mathcal{A}$ is a ***rank-one tensor***.

The ***rank*** of an order-N tensor $\mathcal{A}$ is the minimum number of rank-one tensors that sum to $\mathcal{A}$. For $\mathcal{A} \in \mathcal{R}^{I \times J \times K}$ (illustrated for notational simplicity), its rank decomposition is of the form

$$\mathcal{A} = \sum_{i=1}^{r} x_i \circ y_i \circ z_i, \tag{2}$$

where r is minimal, $x_i \in \mathcal{R}^I$, $y_i \in \mathcal{R}^J$, and $z_i \in \mathcal{R}^K$ for $i = 1, \ldots, r$.

The ***maximum rank*** of a tensor is the largest attainable rank for that given order and sized tensor.

The ***typical rank*** of a tensor is any rank that occurs with probability greater than zero (i.e., on a set with positive Lebesgue measure).

Let $\mathcal{A}$ be an order-N tensor. The ***Higher-Order Singular Value Decomposition*** (***HOSVD***) is a sum of rank-one tensors where the corresponding vectors are orthonormal. If $N = 3$ and $\mathcal{A} \in \mathcal{R}^{I \times J \times K}$ this is usually written as

$$\mathcal{A} = \sum_{i=1}^{I} \sum_{j=1}^{J} \sum_{k=1}^{K} \sigma_{ijk} (u_i \circ v_j \circ w_k), \tag{3}$$

where u_i, v_j, w_k are the ith, jth, kth columns of orthogonal matrices U, V, W, respectively and σ_{ijk} are elements from the tensor $\Sigma \in \mathcal{R}^{I \times J \times K}$.

Facts:

1. A first-order tensor is a vector, a second-order tensor is a matrix, a third-order tensor is a "cube," and so on.

2. Suppose the SVD of $A \in \mathcal{R}^{m\times n}$ is given by $A = U\Sigma V^T$. Using the outer product notation, equation (1) can be re-written as

$$A = \sum_{i=1}^{r} \sigma_i(u_i \circ v_i). \tag{4}$$

3. The definition of rank for matrices and order-2 tensors coincide. Indeed, the minimal r such that a matrix A is a sum of rank-one matrices is given by its SVD.

4. The HOSVD, illustrated for order-3 tensors in (3), is not a rank-revealing decomposition for tensors of order $N \geq 3$.

5. Extending (4) for higher-order tensors defines the rank of a higher-order tensor. The extension is easily seen by comparing (2) and (4). In contrast with matrices, the set of vectors in (2) is not necessarily orthogonal, whereas a rank decomposition for matrices can be chosen to be the SVD in which case the columns of U and V in (4) are orthonormal. Furthermore, it can be shown that an orthogonal rank decomposition of the form (2) may not exist.

6. The HOSVD can be computed directly by computing the SVDs of matrix "flattenings" in each dimension. Therefore, the HOSVD exists for any tensor $\mathcal{A}$ [GoVL13, §12.5], [KoBa09], [DeDeVa00].

7. The maximum rank and typical rank for order-2 tensors (matrices) are identical. If $A \in \mathcal{R}^{m\times n}$ then the maximum (typical) rank of A is $\min(m, n)$.

8. Suppose $\mathcal{A}$ is an order-N real-valued tensor, where $N \geq 3$. There are several differences between tensor rank and matrix rank:

- rank($\mathcal{A}$) may be different when considered over $\mathcal{R}$ and $\mathcal{C}$. See [Ma11], [KoBa09] for examples and explanations. Contrast this with matrices where the rank (and SVD) is the same when a real-valued matrix is considered over $\mathcal{R}$ and $\mathcal{C}$.
- Except in special cases, there is no direct algorithm to determine rank($\mathcal{A}$), and in fact the problem is NP-hard [Ha90]. In practice the rank of a tensor is determined numerically by iterative algorithms; see [KoBa09].
- $\mathcal{A}$ may have a different maximum and typical rank.
- $\mathcal{A}$ may have more than one typical rank, whereas a tensor over $\mathcal{C}$ always has one typical rank.
- If $\mathcal{A} \in \mathcal{R}^{I\times J\times K}$, only the weak upper bound on its maximum rank is known:

$$\text{rank}(\mathcal{A}) \leq \min\{IJ, IK, JK\}.$$

- If $\mathcal{A} \in \mathcal{R}^{2\times 2\times 2}$, then the maximum rank of $\mathcal{A}$ is 3 over $\mathcal{R}$ and 2 over $\mathcal{C}$. The typical ranks of $\mathcal{A}$ are 2 and 3 (when considered over $\mathcal{R}$).
- If $\mathcal{A} \in \mathcal{R}^{n\times n\times 2}$, then the maximum rank of $\mathcal{A}$ is $3n/2$ over $\mathcal{R}$ and n over $\mathcal{C}$. The typical ranks for $\mathcal{A}$ are either n or $n + 1$. See [KoBa09], [CoEtal09] for more special cases of typical rank.

9. Fact 10, §6.7.1 does not extend to tensors of order $N \geq 3$. The best low-rank approximation to a higher-order tensor may not exist.

10. The ordering of the dimensions of the tensor does not affect the rank.

Examples:

1. The set of $n \times n \times n$ real-valued rank-deficient tensors $\mathcal{A}$ over $\mathcal{R}$ has nonzero measure. If $\mathcal{A} \in \mathcal{R}^{2\times 2\times 2}$, Monte Carlo simulations show that a rank-2 tensor is generated 79% of the time and a rank-3 tensor is generated 21% of the time.

2. Suppose $\mathcal{A} \in \mathcal{R}^{2\times 2\times 2}$ where the front and back slices of $\mathcal{A}$ are defined respectively by the matrices

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

Then rank$(\mathcal{A}) = 3$ over $\mathcal{R}$:

$$\mathcal{A} = \left(\begin{bmatrix} 1 \\ 0 \end{bmatrix} \circ \begin{bmatrix} 1 \\ 0 \end{bmatrix} \circ \begin{bmatrix} 1 \\ -1 \end{bmatrix} \right) + \left(\begin{bmatrix} 0 \\ 1 \end{bmatrix} \circ \begin{bmatrix} 0 \\ 1 \end{bmatrix} \circ \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right) + \left(\begin{bmatrix} 1 \\ -1 \end{bmatrix} \circ \begin{bmatrix} 1 \\ 1 \end{bmatrix} \circ \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right).$$

However, rank$(\mathcal{A}) = 2$ over $\mathcal{C}$:

$$\mathcal{A} = \left(\begin{bmatrix} 1/\sqrt{2} \\ -i/\sqrt{2} \end{bmatrix} \circ \begin{bmatrix} 1/\sqrt{2} \\ i/\sqrt{2} \end{bmatrix} \circ \begin{bmatrix} 1 \\ i \end{bmatrix} \right) + \left(\begin{bmatrix} 1/\sqrt{2} \\ i/\sqrt{2} \end{bmatrix} \circ \begin{bmatrix} 1/\sqrt{2} \\ -i/\sqrt{2} \end{bmatrix} \circ \begin{bmatrix} 1 \\ -i \end{bmatrix} \right).$$

3. The HOSVD is a form of higher-order PCA (see §6.7.4) where the matrices U, V, W in (3) are thought of as the principal components in each dimension. The tensor $\Sigma = (\sigma_{ijk})$ in (3) is called the *core tensor* and its entries give the interaction between the different components. However, the higher-order PCA is used as a dimension reduction technique and therefore usually has the following form, illustrated for $\mathcal{A} \in \mathcal{R}^{I\times J\times K}$

$$\mathcal{A} \approx \sum_{i=1}^{P} \sum_{j=1}^{Q} \sum_{k=1}^{R} \sigma_{ijk} (u_i \circ v_j \circ w_k), \tag{5}$$

where $P < I, Q < J, R < K$ and u_i, v_j, w_k are the ith, jth, kth columns of matrices $U \in \mathcal{R}^{I\times P}$, $V \in \mathcal{R}^{J\times Q}$, $W \in \mathcal{R}^{K\times R}$, respectively where U, V, W (usually) have orthonormal columns.

4. The Eigenfaces algorithm (Example 3, §6.7.4) has been generalized for higher-order tensors as *TensorFaces* [VaTe02].

DISCRETE PROBABILITY

INTRODUCTION

This chapter discusses aspects of discrete probability that are relevant to mathematics, computer science, engineering, and other disciplines. Topics covered include random variables, important discrete probability distributions, random walks, Markov models, queues, simulation, and the probabilistic method. Various applications to genetics, telephone network performance, reliability, average-case algorithm analysis, and combinatorics are presented.

GLOSSARY

absorbing boundary: a boundary that stops the motion of a random walk whose trajectory comes into contact with it.

all-terminal reliability: the probability that a given network is connected.

antithetic variates: a variance reduction technique, based on negatively correlated variates, used in the simulation analysis of a given system.

aperiodic state: a state of a Markov chain that is not periodic.

arrival process: the statistical description of the time between successive arrivals to a queueing system.

average-case complexity (of an algorithm): the average number of operations required by the algorithm, taken over all problem instances of a given size.

Bernoulli random variable: the discrete random variable $X \in \{0,1\}$ with probability distribution $Pr(X=0) = 1-p$ and $Pr(X=1) = p$, for some $0 < p < 1$.

binomial random variable: the discrete random variable $X \in \{0,1,\ldots,n\}$ with probability distribution $Pr(X=k) = \binom{n}{k}p^k(1-p)^{n-k}$, for some $0 < p < 1$.

Bose-Einstein model: a probability model in which k indistinguishable balls are randomly placed into n distinguishable urns; several balls are allowed to occupy the same urn.

boundary: a point or set of points restricting the trajectory of a random walk.

branching process: a special type of Markov chain used to model the growth, and possible extinction, of populations.

closed class: a communicating class of states of a Markov chain in which transitions from these states never lead to states outside the class.

coherent system: a system of components for which increasing the number of operating components will not degrade the performance of the system.

common random numbers: a variance reduction technique in which alternative system configurations are analyzed using the same set of random numbers.

communicating class: a maximal set of states in a Markov chain that are reachable from one another by a finite number of transitions.

conditional probability: the probability $Pr(A|B)$ that the event A occurs, given that another event B has occurred.

cutset: a minimal set of edges in a graph the removal of which disconnects the graph.

decoding problem (for an HMM): the problem of determining the most likely sequence of states that could have generated the observed data of an HMM with specified parameters.

density function: a nonnegative real-valued function $f(x)$ that determines the distribution of a continuous random variable X via $Pr(a < X < b) = \int_a^b f(x)\,dx$.

dependent events: events that are not independent.

discrete-event simulation: a simulation of a time-evolving stochastic process in which changes to the state of the system can only occur at discrete instants.

discrete-time Markov chain: a probabilistic model of a randomly evolving system whose future is independent of the past if the present state is known.

distribution (of a random variable): a probability measure associated with the values attained by the random variable.

elastic boundary: a boundary that could be absorbing or reflecting, usually depending on some given probability.

evaluation problem (for an HMM): the problem of determining the probability of obtaining the observed data produced by an HMM with specified parameters.

event: a subset of the sample space.

expected value (of a random variable): the average value taken on by the random variable.

experiment: any physically or mentally conceivable action having a measurable result.

extinction probability: in a branching process, the probability that the population eventually dies out.

Fermi-Dirac model: a probability model in which k indistinguishable balls are randomly placed into n distinguishable urns; at most one ball can occupy each urn.

first passage time: the time to first visit a given set of states in a Markov chain.

floating-point arithmetic: the “real number” arithmetic of computers.

flop: a unit for floating-point computations that is useful in assessing the complexity of an algorithm.

gambler’s ruin: a one-dimensional random walk in which a gambler wins or loses one unit at each play of a game, with the game terminating whenever the gambler amasses a known amount or loses the entire initial stake.

geometric random variable: the discrete random variable $X \in \{1, 2, \ldots\}$ with probability distribution $Pr(X = k) = (1 - p)^{k-1}p$, for some $0 < p < 1$.

hidden Markov model (***HMM***): a stochastic model in which (hidden) states follow a Markov chain, yet one only observes a sequence of state-dependent outcomes.

hypergeometric random variable: the discrete random variable that counts the number of red balls obtained when randomly selecting a fixed number of balls from an urn containing a specified number of red and black balls.

independent events: events in which knowledge of whether one of the events did or did not occur does not alter the probability of occurrence of any of the other events.

independent random variables: random variables whose joint distribution is the product of their individual distributions.

irreducible chain: a Markov chain that can visit any state from any other state in a finite number of steps.

irrelevant edge: an edge of a two-terminal network not appearing on any simple path joining the two terminals of the network.

K-cutset: a minimal set of edges in a graph, the removal of which disconnects some pair of vertices in K.

K-tree: a minimal set of edges in a graph that connects all vertices in K.

learning problem (for an HMM): the problem of finding parameters of an HMM that are most likely to have produced the observed data.

machine unit: a measure of the precision of floating-point arithmetic.

Maxwell-Boltzmann model: a probability model in which k distinguishable balls are randomly placed into n distinguishable urns; several balls can occupy the same urn.

mincut: a minimal set of components in a coherent system such that the system fails whenever these specified components fail.

minpath: a minimal set of components in a coherent system such that the system operates whenever these specified components operate.

Monte Carlo simulation: a simulation used to study both deterministic and stochastic phenomenon in which the passage of time is not material.

overflow: the result of a floating-point arithmetic operation that exceeds the available range of numbers.

parallel system: a system of components that fails only when all components fail.

periodic state: a state of a Markov chain that can only be revisited at multiples of a certain number $d > 1$ (the *period* of the state).

Poisson random variable: the discrete random variable $X \in \{0, 1, \ldots\}$ with probability distribution $Pr(X = k) = \frac{e^{-\lambda}\lambda^k}{k!}$, for some $\lambda > 0$.

probability: a numerical value between 0 and 1 measuring the likelihood of occurrence of an event; the larger the number, the more likely the event.

pseudo-random numbers: numbers generated in a predictable fashion, but that appear to behave like independent and identically distributed random numbers.

purely multiplicative linear congruential generator: a widely used method of producing a stream of pseudo-random numbers.

queue capacity: the maximum number of customers allowed at any time in a queueing system, either waiting or being served.

queue discipline: the protocol according to which customers are selected for service from among those waiting for service.

queueing system: a stochastic process in which customers arrive, await service, and are served.

queue-length process: a stochastic process describing the number of customers in the queueing system.

Ramsey number $R(k,k)$: the smallest integer N such that any coloring of the edges of the complete graph on $n \geq N$ vertices possesses a complete subgraph on k vertices with all edges colored the same.

random numbers: real numbers generated uniformly over the interval $(0,1)$.

random variable: a function that assigns a real number to each outcome in the sample space.

random walk: a stochastic process based on the problem of determining the probable location of a point subject to random motions.

recurrent state: a state of a Markov chain from which the probability of return to itself is 1.

recurrent walk: a random walk that returns to its starting location with probability 1.

reflecting boundary: a boundary that redirects the motion of a random walk whose trajectory comes into contact with it.

relative error: the (percent) error in a computation relative to the true value.

reliability: the probability that a given system functions at a random instant of time.

roundoff error: the error resulting from abbreviating a number to the precision of the machine.

sample size: the number of possible outcomes of an experiment.

sample space: the set of all possible outcomes of an experiment.

series system: a system of components that operates only when all components operate.

service-time distribution: the statistical distribution of time required to serve a customer in a queueing system.

simple path: a path containing no repeated vertices.

simulation: a technique for studying numerically the behavior of complex stochastic systems and estimating their performance.

single-station queueing system: a system in which customers arrive at a service facility, wait for service, and depart after service completion.

s-t cutset: a minimal set of edges in a graph the removal of which leaves no s-t path.

stability condition: the set of parameter values for which the queue-length process (or the waiting-time process) has a steady-state distribution.

steady-state distribution: in a queueing system, the limiting probability distribution of the number of customers in the system.

stochastic process: a collection of random variables, typically indexed by time (discrete or continuous).

structure function: a binary-valued function defined on all subsets of components; its value indicates whether or not the system operates when the specified components all operate.

traffic intensity: in a queueing system, the ratio of the maximum arrival rate to the maximum service rate.

trajectory: the successive positions traced out by a particle undergoing a random walk.

transient state: a state in a Markov chain from which the probability of return to itself is less than 1.

transient walk: a random walk that is not recurrent.

transition probability: the probability of reaching a specified state in a Markov chain by a single transition (step) from a given state.

transition probability matrix: the matrix of one-step transition probabilities for a Markov chain.

two-terminal network: a network in which two vertices (or terminals) are specified.

two-terminal reliability: the probability that the specified vertices of a two-terminal network are connected by a path of operating edges.

underflow: the result of a floating-point operation that is smaller than the smallest representable number.

uniform random variable: the continuous random variable $X \in (\alpha, \beta)$ with density function $f(x) = \frac{1}{\beta - \alpha}$.

variance (of a random variable): a measure of dispersion of the random variable, equal to the average square of the deviation of the random variable from its expected value.

variance reduction techniques: methods for obtaining greater precision for a fixed amount of sampling.

waiting-time process: a stochastic process describing the time spent in the system by the customers.

7.1 FUNDAMENTAL CONCEPTS

Definitions:

An ***experiment*** is any physically or mentally conceivable undertaking that results in a measurable outcome.

The ***sample space*** is the set Ω of all possible outcomes of an experiment.

The ***sample size*** of an experiment is the number of possible outcomes of the experiment.

An ***event*** in the sample space Ω is a subset of Ω.

For a family of events $\{A_j \mid j \in J\}$, the ***union*** $\bigcup\limits_{j \in J} A_j$ is the set of outcomes belonging to at least one A_j; the ***intersection*** $\bigcap\limits_{j \in J} A_j$ is the set of all outcomes belonging to every A_j.

The ***complement*** $\overline{A}$ of an event A is the set of outcomes in the sample space not belonging to A.

The events A and B are ***disjoint*** if $A \cap B = \emptyset$. The events $A_1, A_2, A_3, \ldots$ are ***pairwise disjoint*** if every pair A_i, A_j of distinct events is disjoint.

A ***probability measure*** on the sample space Ω is a function Pr from the set of subsets of Ω into the interval $[0,1]$ satisfying

- $Pr(\Omega) = 1$;
- $Pr(\bigcup\limits_{k=1}^{\infty} A_k) = \sum\limits_{k=1}^{\infty} Pr(A_k)$, if the events $\{A_k\}$ are pairwise disjoint.

A ***fair*** (***unbiased***) ***coin*** is a coin that is just as likely to land Heads (H) as it is to land Tails (T).

A ***red/blue spinner*** is a disk consisting of two sectors, one red with area r and one blue with area b.

Facts:

1. $Pr(\emptyset) = 0$.

2. $Pr(A)$ has the interpretation as the long-run proportion of time that the event A occurs in repeated trials of the experiment.

3. $Pr(\bigcup\limits_{k=1}^{n} A_k) = \sum\limits_{k=1}^{n} Pr(A_k)$, if the n events $\{A_k\}$ are pairwise disjoint.

4. If all outcomes are equally likely and the sample space has k elements, where k is a positive integer, then the probability of event A is the number of elements of A divided by the size of the sample space; that is, $Pr(A) = \frac{|A|}{k}$.

5. *Principle of inclusion-exclusion (simple form)*: For events A and B,

$$Pr(A \cup B) = Pr(A) + Pr(B) - Pr(A \cap B).$$

6. *Principle of inclusion-exclusion (general form)*: For any events $A_1, A_2, \ldots, A_n$,

$$Pr(\bigcup_{r=1}^{n} A_r) = \sum_i Pr(A_i) - \sum_{i<j} Pr(A_i \cap A_j) + \sum_{i<j<k} Pr(A_i \cap A_j \cap A_k) - \cdots + (-1)^{n+1}\, Pr(A_1 \cap A_2 \cap \cdots \cap A_n).$$

7. *Sieve principle*: If $A_1, A_2, \ldots, A_n$ are events, then

$$Pr(\text{ exactly } k \text{ of the } A_j \text{ occur }) = \sum_{r=k}^{n} (-1)^{r+k} \tbinom{r}{k} \sum_{j_1<j_2<\cdots<j_r} Pr(A_{j_1} \cap A_{j_2} \cap \cdots \cap A_{j_r}).$$

8. *Boole's inequality*: If $A_1, A_2, \ldots, A_n$ are events, then

$$Pr(\bigcup_{k=1}^{n} A_k) \le \sum_{k=1}^{n} Pr(A_k).$$

If $A_1, A_2, \ldots$ is an infinite sequence of events, then

$$Pr(\bigcup_{k=1}^{\infty} A_k) \le \sum_{k=1}^{\infty} Pr(A_k).$$

(George Boole, 1815–1864.)

9. *Bonferroni's inequality*: If $A_1, A_2, \ldots, A_n$ are events, then

$$Pr(\bigcup_{k=1}^{n} A_k) \geq \sum_{k=1}^{n} Pr(A_k) - \sum_{k<j} Pr(A_k \cap A_j).$$

10. $Pr(\overline{A}) = 1 - Pr(A)$.

11. *Monotonicity*: If $A \subseteq B$, then $Pr(A) \leq Pr(B)$.

12. If $A_1 \subseteq A_2 \subseteq A_3 \subseteq \cdots$ is an increasing sequence of events, then

$$\lim_{n\to\infty} Pr(A_n) = Pr(\bigcup_{n=1}^{\infty} A_n).$$

13. If $A_1 \supseteq A_2 \supseteq A_3 \supseteq \cdots$ is a decreasing sequence of events, then

$$\lim_{n\to\infty} Pr(A_n) = Pr(\bigcap_{n=1}^{\infty} A_n).$$

Examples:

1. The following table gives examples of specific experiments, their sample spaces, and the corresponding sample size.

experiment	*sample space*	*sample size*
toss a coin	$\{H, T\}$	2
toss a coin n times	$\{(\omega_1, \ldots, \omega_n) \mid \omega_i$ is H or $T\}$	2^n
roll a die	$\{1, 2, 3, 4, 5, 6\}$	6
roll a pair of dice	$\{(1,1), (1,2), \ldots, (6,5), (6,6)\}$	36
draw a card from a standard deck	$\{2\clubsuit, 2\diamondsuit, \ldots, A\heartsuit, A\spadesuit\}$	52
spin a red/blue spinner	{red, blue}	2

2. The following are various events defined for the experiment of rolling a pair of dice (see the table of Example 1).

sum of dice is 9: $A = \{(3,6), (4,5), (5,4), (6,3)\}$
both dice are multiples of 3: $B = \{(3,3), (3,6), (6,3), (6,6)\}$
sum of dice ≤ 4: $C = \{(1,1), (1,2), (1,3), (2,1), (2,2), (3,1)\}$.

3. The events $A = \{$sum of dice $= 9\}$ and $C = \{$sum of dice $\leq 4\}$ are disjoint. The events $A_i = \{$sum of the dice is $i\}$, $2 \leq i \leq 12$, are pairwise disjoint.

4. *Random selection of an integer*: Let $\Omega = \{1, 2, 3, \ldots, n\}$ be the sample space corresponding to the experiment of randomly selecting an integer between 1 and n, and define $Pr(j) = Pr(\{j\}) = \frac{1}{n}$. By Fact 4, $Pr(3 \leq j \leq n) = Pr(\{3 \leq j \leq n\}) = \frac{n-2}{n}$.

5. For a red/blue spinner, the sample space is $\Omega = \{$red, blue$\}$. If the spinner is equally likely to land at any location, then $Pr(\text{red}) = \frac{r}{r+b}$ and $Pr(\text{blue}) = \frac{b}{r+b}$.

6. Toss a fair coin n times and interpret Heads as 1 and Tails as 0. The sample space $\Omega = \{(\omega_1, \omega_2, \ldots, \omega_n) \mid \omega_j \in \{0,1\}\}$ consists of all possible 0-1 sequences of length n. Since $|\Omega| = 2^n$, each probability $Pr((\omega_1, \omega_2, \ldots, \omega_n))$ is assigned the value $\frac{1}{2^n}$. By Fact 4, $Pr(A) = \frac{|A|}{2^n}$ holds for all $A \subseteq \Omega$.

For example, the probability of no tails appearing in four coin tosses is the probability of event $A = \{(1,1,1,1)\}$, so $Pr(A) = \frac{1}{16}$. The probability of exactly one tail is the probability of event $B = \{(0,1,1,1), (1,0,1,1), (1,1,0,1), (1,1,1,0)\}$; hence $Pr(B) = \frac{4}{16} = \frac{1}{4}$. The probability of at least two tails is, using Fact 10, $1 - Pr(A) - Pr(B) = 1 - \frac{5}{16} = \frac{11}{16}$.

7. *Derangements*: Let D_n be the set of derangements (§2.4.2) on the n elements $\{1,2,\ldots,n\}$ and define A_j to be the set of all permutations fixing j. For any permutation σ, $Pr(\sigma)=\frac{1}{n!}$. Also, for $j_1<j_2<\cdots<j_k$, $Pr(A_{j_1}\cap A_{j_2}\cap\cdots\cap A_{j_k})=\frac{(n-k)!}{n!}$ and $\sum_{j_1<j_2<\cdots<j_k} Pr(A_{j_1}\cap A_{j_2}\cap\cdots\cap A_{j_k})=\binom{n}{k}\frac{(n-k)!}{n!}=\frac{1}{k!}$. By Fact 6, $Pr(\bigcup_{r=1}^{n} A_r)=\sum_i Pr(A_i)-\sum_{i<j} Pr(A_i\cap A_j)+\sum_{i<j<k} Pr(A_i\cap A_j\cap A_k)-\cdots+(-1)^{n+1} Pr(A_1\cap A_2\cap\cdots\cap A_n)=1-\frac{1}{2!}+\frac{1}{3!}-\cdots+(-1)^{n+1}\frac{1}{n!}$. Hence, $Pr(D_n)=1-1+\frac{1}{2!}-\frac{1}{3!}-\cdots+\frac{(-1)^n}{n!}\approx e^{-1}\approx 0.36788$.

8. *5-card stud poker*: Five cards are drawn from a well-shuffled deck of 52 playing cards. The sample space consists of the $\binom{52}{5}=2{,}598{,}960$ possible five-card hands. The approximate probabilities of various events are displayed in the following table. (See §2.3.2, Example 12 for further details.) As seen from the probabilities given in the table, obtaining a five-card hand containing three of a kind is approximately ten times more likely than obtaining a five-card hand containing a flush, which in turn is approximately ten times more likely than obtaining a five-card hand containing four of a kind.

type of hand	*example*	*hand enumeration*	*probability*
one pair	$7\heartsuit, 7\diamondsuit, K\clubsuit, J\spadesuit, 2\heartsuit$	$\binom{13}{1}\binom{4}{2}\binom{12}{3}4^3$	0.42
two pairs	$7\spadesuit, 7\heartsuit, K\diamondsuit, K\spadesuit, 3\clubsuit$	$\binom{13}{2}\binom{4}{2}\binom{4}{2}44$	0.048
three of a kind	$7\clubsuit, 7\heartsuit, 7\diamondsuit, 3\diamondsuit, 5\spadesuit$	$\binom{13}{1}\binom{4}{3}\binom{12}{2}4^2$	0.021
straight	$7\clubsuit, 8\spadesuit, 9\diamondsuit, 10\clubsuit, J\heartsuit$	$10(4^5-4)$	0.0039
flush	$3\diamondsuit, 6\diamondsuit, 7\diamondsuit, J\diamondsuit, K\diamondsuit$	$4(\binom{13}{5}-10)$	0.0020
full house	$3\heartsuit, 3\diamondsuit, 3\spadesuit, 7\clubsuit, 7\heartsuit$	$13\cdot 12\cdot\binom{4}{3}\binom{4}{2}$	0.0014
four of a kind	$A\clubsuit, A\diamondsuit, A\heartsuit, A\spadesuit, 7\spadesuit$	$13\cdot 48$	0.00024
straight flush	$7\diamondsuit, 8\diamondsuit, 9\diamondsuit, 10\diamondsuit, J\diamondsuit$	$\binom{4}{1}9$	0.000014
royal flush	$10\heartsuit, J\heartsuit, Q\heartsuit, K\heartsuit, A\heartsuit$	4	0.0000015

7.2 INDEPENDENCE AND DEPENDENCE

Sequences of independent events are often encountered when an experiment is repeated (without changes). Independent events correspond, intuitively, to events that do not affect the outcome of one another. The treatment of dependent events requires conditional probabilities.

7.2.1 BASIC CONCEPTS

Definitions:

Two events A and B are ***independent*** if $Pr(A\cap B)=Pr(A)\,Pr(B)$.

The n events $A_1,A_2,\ldots,A_n$ are ***independent*** if for all k $(2\le k\le n)$ and $j_1,j_2,\ldots,j_k$ $(1\le j_1<j_2<\cdots<j_k\le n)$,

$$Pr(A_{j_1}\cap A_{j_2}\cap\cdots\cap A_{j_k})=Pr(A_{j_1})\,Pr(A_{j_2})\ldots Pr(A_{j_k}).$$

The infinite collection of events $\{A_n \mid n \geq 1\}$ is ***independent*** if for all finite $k \geq 2$ the events $A_1, A_2, \ldots, A_k$ are independent.

Let B be an event with $Pr(B) > 0$. The ***conditional probability of A given B*** is $Pr(A|B) = \dfrac{Pr(A \cap B)}{Pr(B)}$.

Facts:

1. If events A and B are independent, then so are A and $\overline{B}$, $\overline{A}$ and B, and $\overline{A}$ and $\overline{B}$.

2. If $A_1, A_2, \ldots$ are independent events, then $Pr(\bigcap\limits_{k=1}^{\infty} A_k) = \prod\limits_{k=1}^{\infty} Pr(A_k)$.

3. The function $\phi_B \colon A \to Pr(A|B)$ is a probability measure (§7.1).

4. $Pr(A \cap B) = Pr(A|B)\, Pr(B)$.

5. If A and B are independent, then $Pr(A|B) = Pr(A)$. This equation captures the notion that for independent events A and B the knowledge that one of the events has occurred does not affect the probability of the other occurring.

6. Pairwise independence of a collection of events does not necessarily imply that all events are independent (see Example 3).

7. *Law of total probability*: For any event A and any partition of Ω into the events $B_1, B_2, \ldots, B_n$,

$$Pr(A) = \sum_{i=1}^{n} Pr(A \cap B_i) = \sum_{i=1}^{n} Pr(A|B_i)\, Pr(B_i).$$

8. *Bayes' formula*: For any event A and any partition of Ω into the events $B_1, B_2, \ldots, B_n$,

$$Pr(B_1|A) = \frac{Pr(B_1 \cap A)}{Pr(A)} = \frac{Pr(A|B_1)\, Pr(B_1)}{\sum\limits_{i=1}^{n} Pr(A|B_i)\, Pr(B_i)}.$$

(Thomas Bayes, 1702–1761.)

9. *Chain rule*: For any events $A_1, A_2, \ldots, A_n$ satisfying $Pr(\bigcap\limits_{k=1}^{n-1} A_k) > 0$,

$$Pr(A_1 \cap A_2 \cap \cdots \cap A_n) = Pr(A_1)\ Pr(A_2|A_1)\ Pr(A_3|A_1 \cap A_2) \ldots Pr(A_n \mid \bigcap_{k=1}^{n-1} A_k).$$

Examples:

1. *Tossing two fair coins*: The sample space for this experiment consists of the four outcomes HH, HT, TH, TT. For example, the outcome HT means that the first coin turns up Heads and the second Tails. Because both coins are fair, all four outcomes are equally likely and in particular $Pr(HT) = \frac{1}{4}$. Since $Pr(H) = Pr(T) = \frac{1}{2}$, $Pr(HT) = \frac{1}{4} = \frac{1}{2} \cdot \frac{1}{2} = Pr(H)\, Pr(T)$. Thus, the events "Heads on the first coin" and "Tails on the second coin" are independent.

2. *Tossing a fair coin n times*: As in Example 6 of §7.1, let 1 stand for Heads and 0 for Tails. For each $1 \leq i \leq n$ select $\epsilon_i \in \{0,1\}$ and define $A_i = \{\epsilon_i$ occurs on the ith toss$\}$. Since all outcomes are equally likely, $Pr(A_1 \cap A_2 \cap \cdots \cap A_n) = (\frac{1}{2})^n = \frac{1}{2} \times \frac{1}{2} \times \cdots \times \frac{1}{2} = Pr(A_1)\, Pr(A_2) \ldots Pr(A_n)$. Also, for all $j_1, j_2, \ldots, j_k$ $(2 \leq k \leq n)$, $Pr(A_{j_1} \cap A_{j_2} \cap \cdots \cap A_{j_k}) = (\frac{1}{2})^k = \frac{1}{2} \times \frac{1}{2} \times \cdots \times \frac{1}{2} = Pr(A_{j_1})\, Pr(A_{j_2}) \ldots Pr(A_{j_k})$. Therefore the events $A_1, A_2, \ldots, A_n$ are independent.

3. Let $\Omega = \{a, b, c, d\}$ be a sample space with equiprobable outcomes. Let $A = \{a, b\}$, $B = \{a, c\}$, and $C = \{a, d\}$. Here $Pr(A) = Pr(B) = Pr(C) = \frac{1}{2}$. Also $Pr(A \cap B) = \frac{1}{4} = \frac{1}{2} \cdot \frac{1}{2} = Pr(A)\,Pr(B)$, $Pr(A \cap C) = \frac{1}{4} = \frac{1}{2} \cdot \frac{1}{2} = Pr(A)\,Pr(C)$, and $Pr(B \cap C) = \frac{1}{4} = \frac{1}{2} \cdot \frac{1}{2} = Pr(B)\,Pr(C)$. Yet $Pr(A \cap B \cap C) = \frac{1}{4} \neq \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = Pr(A)\,Pr(B)\,Pr(C)$. In this example, any two of the events are independent, but all three are not.

4. *Gambler's fallacy*: Suppose that a fair coin is tossed five times, turning up Heads on all five tosses. What is the probability that the next (sixth) toss turns up Tails? A common fallacy is to believe that a Tail is more likely to turn up next, since in the long run 50% of the coins should turn up Tails (and 50% Heads).

The appropriate sample space consists of $2^6 = 64$ equiprobable outcomes, representing any sequence of six Heads and/or Tails. The required probability is $Pr(A|B)$, where $A = \{(H, H, H, H, H, T)\}$ and $B = \{(H, H, H, H, H, H), (H, H, H, H, H, T)\}$. Then $Pr(A|B) = \frac{Pr(A \cap B)}{Pr(B)} = \frac{Pr(A)}{Pr(B)} = \frac{1}{2}$. Consequently, a Tail turning up next is just as likely as a Head.

5. An urn contains seven blue marbles and five red marbles. An experiment consists of drawing (without replacement) a marble at random, observing its color, and then drawing a second marble at random. Let B_i be the event "the ith marble drawn is blue" and let R_i be the event "the ith marble drawn is red", where $i \in \{1, 2\}$. Then $Pr(B_1) = \frac{7}{12}$, $Pr(R_2|B_1) = \frac{5}{11}$, $Pr(B_1 \cap R_2) = Pr(R_2|B_1)\,Pr(B_1) = \frac{5}{11} \cdot \frac{7}{12} = \frac{35}{132}$. By Fact 7,

$$Pr(R_2) = Pr(R_2|R_1)\,Pr(R_1) + Pr(R_2|B_1)\,Pr(B_1) = \tfrac{4}{11} \cdot \tfrac{5}{12} + \tfrac{5}{11} \cdot \tfrac{7}{12} = \tfrac{55}{132}.$$

By Fact 8,

$$Pr(B_1|R_2) = \frac{Pr(R_2|B_1)\,Pr(B_1)}{Pr(R_2|R_1)\,Pr(R_1) + Pr(R_2|B_1)\,Pr(B_1)} = \frac{\frac{5}{11} \cdot \frac{7}{12}}{\frac{4}{11} \cdot \frac{5}{12} + \frac{5}{11} \cdot \frac{7}{12}} = \frac{7}{11}.$$

6. A particular family is known to have two children (one 9 years old, the other 10 years old). When a census taker comes to the house, a girl answers the doorbell. What is the probability that the other child is also a girl?

To answer this question, construct the sample space $\Omega = \{(b, b), (b, g), (g, b), (g, g)\}$, where, for example, the ordered pair (b, g) means that the younger child is a boy and the older child is a girl. Assume that all four outcomes in the sample space are equiprobable. The required probability is $Pr(A|B)$, where $A = \{(g, g)\}$ and $B = \{(b, g), (g, b), (g, g)\}$. Then

$$Pr(A|B) = \frac{Pr(A \cap B)}{Pr(B)} = \frac{Pr(\{(g, g)\})}{Pr(\{(b, g), (g, b), (g, g)\})} = \frac{\frac{1}{4}}{\frac{3}{4}} = \frac{1}{3}.$$

7. *Genetics*: Genes are responsible for physical traits of all living things. Each gene is composed of two alleles. Dominant alleles are represented with capital letters and recessive alleles with lower case letters. The basic discoveries concerning genetics were made by Gregor Mendel (1822–1884). One of the genes that is responsible for eye color exhibits two alleles—a dominant one B, for brown eyes, and a recessive one b, for blue eyes. In a certain population the genotype probabilities are

$Pr(\text{an individual has genotype } BB) = 0.2$
$Pr(\text{an individual has genotype } Bb) = 0.5$
$Pr(\text{an individual has genotype } bb) = 0.3.$

Let E_b be the event that an offspring receives a b allele from its mother, and let F_b be the event that it receives a b allele from its father. Conditioning on the genotype (BB, Bb, bb) of the offspring produces

$$\begin{aligned} Pr(E_b) &= Pr(E_b|BB)\,Pr(BB) + Pr(E_b|Bb)\,Pr(Bb) + Pr(E_b|bb)\,Pr(bb) \\ &= 0 \times 0.2 \;+\; 0.5 \times 0.5 \;+\; 1 \times 0.3 = 0.55; \end{aligned}$$

similarly $Pr(F_b) = 0.55$.

Let C be the event that the offspring has blue eyes (that is, has genotype bb). By independence,

$$Pr(C) = Pr(E_b \cap F_b) = Pr(E_b)\,Pr(F_b) = (0.55)^2 = 0.3025.$$

8. In Example 7, let A be the event that the father has blue eyes (has genotype bb). If the father has blue eyes, then the offspring will have blue eyes (event C) if and only if it receives a b allele from its mother, giving $Pr(C|A) = Pr(E_b) = 0.55$. We also have $Pr(C|\text{father is } Bb) = Pr(C \text{ and mother is } Bb|\text{father is } Bb) + Pr(C \text{ and mother is } bb|\text{ father is } Bb) = 0.25 \times 0.5 \;+\; 0.5 \times 0.3 = 0.275$ and $Pr(C|\text{father is } BB) = 0$.

The conditional probability that the father has blue eyes if the offspring has blue eyes is obtained from Fact 8 (interchanging phenotype with genotype when convenient) as

$$\begin{aligned} Pr(A|C) &= \frac{Pr(C|\text{father has } bb)\;Pr(\text{father has } bb)}{Pr(C|bb)\,Pr(bb) + Pr(C|Bb)\,Pr(Bb) + Pr(C|BB)\,Pr(BB)} \\ &= \frac{0.55 \times 0.3}{0.55 \times 0.3 \;+\; 0.275 \times 0.5 \;+\; 0} \approx 0.545. \end{aligned}$$

9. *Let's Make a Deal*: A game show contestant is told there is a fabulous prize hidden behind one of three doors (A, B, or C). The contestant guesses that the prize is behind door A. At this point the game show host (who knows what is behind each door, and in particular knows that the prize is not behind door B) opens door B, revealing that the prize is not there. The contestant is then offered the opportunity to change her guess. Should she? Intuition might suggest that nothing is to be gained by changing the guess (the prize, it is argued, is now equally likely to be behind either door A or door C). Using conditional probabilities, however, shows that it is definitely worthwhile to now guess that the prize is behind door C, assuming that the host is known to always open a door with no prize and to choose randomly if both remaining doors do not hide the prize.

It is reasonable to assume that the prize is equally likely to be hidden behind each of the doors. Thus, if H_X denotes the event in which the prize is hidden behind door X, then $Pr(H_A) = Pr(H_B) = Pr(H_C) = \frac{1}{3}$. If O_X denotes the event that door X is opened, then $Pr(O_B|H_A) = Pr(O_C|H_A) = \frac{1}{2}$, whereas $Pr(O_B|H_B) = 0$ and $Pr(O_B|H_C) = 1$. By Fact 8,

$$\begin{aligned} Pr(H_A|O_B) &= \frac{Pr(H_A \cap O_B)}{Pr(O_B)} \\ &= \frac{Pr(H_A)\,Pr(O_B|H_A)}{Pr(H_A)\,Pr(O_B|H_A) + Pr(H_B)\,Pr(O_B|H_B) + Pr(H_C)\,Pr(O_B|H_C)} \\ &= \frac{\frac{1}{3} \cdot \frac{1}{2}}{\frac{1}{3} \cdot \frac{1}{2} \;+\; 0 \;+\; \frac{1}{3} \cdot 1} = \frac{1}{3}. \end{aligned}$$

Similarly $Pr(H_C|O_B) = \frac{2}{3}$, so it is twice as likely for the prize to be hidden behind door C as behind door A, given that door B is shown to contain no prize. A web-based simulation of this situation, in which prizes are randomly hidden behind doors, enables one to verify experimentally this conclusion; see for example

- `http://math.ucsd.edu/~crypto/Monty/monty.html`

7.2.2 URN MODELS

Several applications can be viewed as the result of placing balls into urns.

Definitions:

In the following models, k balls are randomly placed in n distinguishable urns labeled 1 through n.

- ***Model 1*** (***Maxwell-Boltzmann***): The balls are distinguishable and multiple occupancy is permitted.
- ***Model 2***: The balls are distinguishable and multiple occupancy is not permitted.
- ***Model 3*** (***Fermi-Dirac***): The balls are indistinguishable and multiple occupancy is not permitted.
- ***Model 4*** (***Bose-Einstein***): The balls are indistinguishable and multiple occupancy is permitted.
- ***Model 5***: The balls are distinguishable, no urn is allowed to remain empty, and multiple occupancy is permitted.

Facts:

1. The following table shows, for different urn models, the probability of the event $(k_1, k_2, \ldots, k_n)$, in which k_1 balls are in urn 1, k_2 balls are in urn 2, …, k_n balls are in urn n, with the restrictions $\sum_{j=1}^{n} k_j = k$, $k_j \geq 0$. In Model 2, $n^{\underline{k}}$ is a falling power (see §3.4.2). In Models 2 and 3, every $k_j \in \{0, 1\}$ and the models are meaningful only if $k \leq n$. In Model 5, every $k_j \geq 1$, $k \geq n$, and $\left\{ {k \atop n} \right\}$ is a Stirling subset number (§2.5.2).

model	*sample size*	*enumeration of* $(k_1, \ldots, k_n)$	*probability of* $(k_1, \ldots, k_n)$
1	n^k	$\binom{k}{k_1\ k_2\ \ldots\ k_n}$	$\binom{k}{k_1\ k_2\ \ldots\ k_n} n^{-k}$
2	$n^{\underline{k}}$	$k!$	$\binom{n}{k}^{-1}$
3	$\binom{n}{k}$	1	$\binom{n}{k}^{-1}$
4	$\binom{n+k-1}{k}$	1	$\binom{n+k-1}{k}^{-1}$
5	$n!\left\{ {k \atop n} \right\}$	$\binom{k}{k_1\ k_2\ \ldots\ k_n}$	$\binom{k}{k_1\ k_2\ \ldots\ k_n} / \left(n!\left\{ {k \atop n} \right\}\right)$

2. The Maxwell-Boltzmann model was originally proposed to explain the distribution of k subatomic particles into n different energy states. It has been replaced by the Bose-Einstein model (appropriate for particles with integer "spin", such as photons and pi mesons) and by the Fermi-Dirac model (appropriate for particles with half-integer "spin", such as protons and neutrons).

3. *Pólya's urn scheme* (George Pólya, 1887–1985): In this model, an urn contains b black and r red balls. At each step one ball is drawn and replaced, and c additional balls of the same color are placed in that urn. This scheme models the spread of a contagious disease where an infected person infects c other persons.

4. The case $c = 0$ in Pólya's urn scheme corresponds to sampling balls with replacement.

5. The case $c = -1$ in Pólya's urn scheme corresponds to sampling balls without replacement.

6. The following table shows how to calculate several types of probabilities using Pólya's urn scheme, where b is the number of black balls, r is the number of red balls, and c is the number of additional balls added each time.

event	*probability*
drawing a black	$\frac{b}{b+r}$
drawing a black then red	$\frac{br}{(b+r)(b+r+c)}$
drawing in order black, red, black	$\frac{br(b+c)}{(b+r)(b+r+c)(b+r+2c)}$
drawing k black and $n-k$ red balls in a prescribed order	$\frac{b(b+c)\ldots(b+(k-1)c)r(r+c)\ldots(r+(n-k-1)c)}{(b+r)(b+r+c)(b+r+2c)\ldots(b+r+(n-1)c)}$
drawing k black balls in n drawings; the order of drawing does not matter	$\frac{\binom{-b/c}{k}\binom{-r/c}{n-k}}{\binom{-(b+r)/c}{n}}$

Examples:

1. *Partial derivatives*: For analytic functions f, the order in which derivatives are taken does not matter. As an example, the mixed second partial derivatives f_{xy} and f_{yx} are equal, as are f_{xxy} and f_{xyx}. Consequently, the number of different third-order partial derivatives of a function of n variables is the number of ways to distribute $k = 3$ indistinguishable balls into n urns (variables). Each such distribution corresponds to selecting the number of times each variable occurs in forming the partial derivative. Using the entry for Model 4 in the table for Fact 1, there are $\binom{n+2}{3}$ third-order partial derivatives of f. When $n = 3$ this gives $\binom{5}{3} = 10$ different third-order partial derivatives of $f(x, y, z)$: namely, $f_{xxx}, f_{yyy}, f_{zzz}, f_{xxy}, f_{xxz}, f_{xyy}, f_{yyz}, f_{xzz}, f_{yzz}, f_{xyz}$. In general, there are $\binom{n+k-1}{k}$ different kth-order partial derivatives of f.

2. Model 3 provides a model for the occurrence of misprints on the pages of a book. Here the n urns correspond to the n symbols printed sequentially in the book and k is the number of misprints. Each symbol is either correct or a misprint, so multiple occupancy does not occur.

Also, assuming that the misprints are not generated in a systematic fashion, the k balls can be considered indistinguishable, with misprints equally likely to occur at any location on the page.

3. *Lottery odds*: A lottery is conducted by selecting five different numbers from $1, 2, \ldots, 9$. This can be viewed using urn Model 3, in which the five selected numbers correspond to $k = 5$ identical balls placed into $n = 9$ distinguished urns. The number of such selections, by the table of Fact 1, is $\binom{9}{5} = 126$. Only one of these 126 selections matches all the five winning numbers, so $Pr(\text{match } 5) = \frac{1}{126}$.

To match exactly four of the five winning numbers, select the matching numbers in $\binom{5}{4} = 5$ ways and select the (single) nonmatching number in $\binom{4}{1} = 4$ ways, giving $Pr(\text{match } 4) = \frac{5\cdot 4}{126} = \frac{20}{126}$.

To match exactly three of the winning numbers, select the matching numbers in $\binom{5}{3} = 10$ ways and select the two nonmatching numbers in $\binom{4}{2} = 6$ ways, giving $Pr(\text{match } 3) = \frac{10\cdot 6}{126} = \frac{60}{126}$.

4. In a number of state lotteries, $k = 6$ numbers are drawn from $1, 2, \ldots, n$. The following table gives the probability of matching exactly six, exactly five, and exactly four of the six winning numbers, for values of $n = 35, \ldots, 60$.

n	*match* 6	*match* 5	*match* 4
35	1/1,623,160	87/811,580	87/23,188
36	1/1,947,792	15/162,316	2,175/649,264
37	1/2,324,784	31/387,464	2,325/774,928
38	1/2,760,681	64/920,227	2,480/920,227
39	1/3,262,623	66/1,087,541	2,640/1,087,541
40	1/3,838,380	17/319,865	561/255,892
41	1/4,496,388	35/749,398	2,975/1,498,796
42	1/5,245,786	108/2,622,893	675/374,699
43	1/6,096,454	111/3,048,227	4,995/3,048,227
44	1/7,059,052	57/1,764,763	10,545/7,059,052
45	1/8,145,060	39/1,357,510	741/543,004
46	1/9,366,819	80/3,122,273	3,900/3,122,273
47	1/10,737,573	82/3,579,191	4,100/3,579,191
48	1/12,271,512	21/1,022,626	4,305/4,090,504
49	1/13,983,816	43/2,330,636	645/665,896
50	1/15,890,700	22/1,324,225	473/529,690
51	1/18,009,460	27/1,800,946	1,485/1,800,946
52	1/20,358,520	69/5,089,630	3,105/4,071,704
53	1/22,957,480	141/11,478,740	3,243/4,591,496
54	1/25,827,165	32/2,869,685	376/573,937
55	1/28,989,675	98/9,663,225	392/644,215
56	1/32,468,436	25/2,705,703	875/1,546,116
57	1/36,288,252	17/2,016,014	2,125/4,032,028
58	1/40,475,358	52/6,745,893	1,105/2,248,631
59	1/45,057,474	53/7,509,579	3,445/7,509,579
60	1/50,063,860	81/12,515,965	4,293/10,012,772

5. Let an urn contain $c = 1$ red ball and $b = 9$ black balls. In Pólya's urn scheme with $c = 1$, the probability of obtaining the sequence RRB (two red balls and then a black ball) is found using conditional probabilities as

$$Pr(RRB) = Pr(B|RR)\, Pr(R|R)\, Pr(R) = \tfrac{9}{12} \cdot \tfrac{2}{11} \cdot \tfrac{1}{10}.$$

Likewise,

$$Pr(BRR) = Pr(R|BR)\, Pr(R|B)\, Pr(B) = \tfrac{2}{12} \cdot \tfrac{1}{11} \cdot \tfrac{9}{10},$$

and

$$Pr(RBR) = Pr(R|RB)\, Pr(B|R)\, Pr(R) = \tfrac{2}{12} \cdot \tfrac{9}{11} \cdot \tfrac{1}{10}.$$

Thus,

$$Pr(RRB) = Pr(BRR) = Pr(RBR) = \tfrac{3}{220},$$

agreeing with the value obtained using the table of Fact 6, with $k = 1$ and $n = 3$.

The probability of obtaining two red balls and one black ball in some order is then $Pr(RRB) + Pr(BRR) + Pr(RBR) = \frac{9}{220}$. Using the extended binomial coefficients (§2.3.2), the corresponding entry in the table of Fact 6 can be verified for this case, where $k = 1$ and $n = 3$:

$$Pr(\text{ exactly one black ball }) = \frac{\binom{-9}{1}\binom{-1}{2}}{\binom{-10}{3}} = \frac{(-1)^1\binom{9}{1}(-1)^2\binom{2}{2}}{(-1)^3\binom{12}{3}} = \frac{9}{220},$$

agreeing with the value already found.

7.3 RANDOM VARIABLES

7.3.1 DISTRIBUTIONS

Definitions:

A ***random variable*** X is a real-valued function on a probability space Ω.

The random variable $X\colon \Omega \to \mathcal{R}$ is ***discrete*** if the range of X is finite or countable.

The real-valued function $f\colon \mathcal{R} \to \mathcal{R}$ is a ***density function*** if

- $f(x) \geq 0$ for all $x \in \mathcal{R}$;
- $\int_{-\infty}^{\infty} f(x)\, dx = 1$.

The random variable X is (***absolutely***) ***continuous*** if there exists a density function f such that $Pr(a < X < b) = \int_a^b f(x)\, dx$ for all $a < b$.

The ***distribution*** μ_X of the random variable X is given by $\mu_X(B) = Pr(X \in B)$ for every interval B.

The ***cumulative distribution function*** of a random variable X is given by $F(x) = Pr(X \leq x)$.

A ***random vector*** is a function $X = (X_1, \ldots, X_k)\colon \Omega \to \mathcal{R}^k$.

The ***joint distribution*** $\mu_{X_1,\ldots,X_k}$ of the random vector $(X_1, \ldots, X_k)$ is defined by $\mu_{X_1,\ldots,X_k}(B_1, \ldots, B_k) = Pr(X_1 \in B_1, \ldots, X_k \in B_k)$ for any k intervals $B_1, \ldots, B_k$.

The random variables $X_1, \ldots, X_n$ are ***independent*** if for any intervals $B_1, \ldots, B_n$ $Pr(X_1 \in B_1, \ldots, X_n \in B_n) = Pr(X_1 \in B_1) \ldots Pr(X_n \in B_n)$.

Facts:

1. The cumulative distribution function $F(x)$ is a nondecreasing function of x.

2. $\lim_{x\to\infty} F(x) = 1$, $\lim_{x\to-\infty} F(x) = 0$.

3. $Pr(a < X \leq b) = F(b) - F(a)$ for $a < b$.

4. If X is a discrete random variable, then $\sum_k Pr(X = k) = 1$.

5. If X is a continuous random variable, then $\frac{d}{dx}F(x) = f(x)$.

6. Some important discrete random variables are described in Table 1. Here $q = 1 - p$.

Table 1: Discrete random variables.

distribution	*description of event* $(X = k)$	*range of* X	$Pr(X = k)$
Bernoulli $B(1, p)$	$k = 0$ indicates a failure, $k = 1$ indicates a success	$0, 1$	q p
binomial $B(n, p)$	k successes in n trials, each with probability p of success	$0, 1, \ldots, n$	$\binom{n}{k} p^k q^{n-k}$
Poisson $P(\lambda)$	k arrivals to a counter over a unit period of time, at average rate λ	$0, 1, 2, \ldots$	$\frac{e^{-\lambda}\lambda^k}{k!}$
geometric $G(p)$	k trials before first success occurs	$1, 2, \ldots$	$q^{k-1}p$
Pascal $NB(r, p)$	k trials before rth success occurs	$r, r+1, \ldots$	$\binom{k-1}{r-1} q^{k-r} p^r$
hypergeometric (N, m, n)	sample n items from N items, where m are defective and $N - m$ are not; k = number of defectives selected	$0, 1, \ldots, n$	$\frac{\binom{m}{k}\binom{N-m}{n-k}}{\binom{N}{n}}$

7. Some important continuous random variables are described in Table 2. Here it is understood that the density function $f(x) = 0$ outside the specified range.

8. If X_1 and X_2 are independent binomial random variables (see Table 1) with parameters n_1, p and n_2, p, respectively, then $X_1 + X_2$ is also a binomial random variable with parameters $n_1 + n_2, p$.

9. If X_1 and X_2 are independent Poisson random variables (see Table 1) with parameters λ_1 and λ_2, respectively, then $X_1 + X_2$ is also a Poisson random variable with parameter $\lambda_1 + \lambda_2$.

10. If X_1 and X_2 are independent normal random variables (see Table 2) with parameters μ_1, σ_1^2 and μ_2, σ_2^2, respectively, then $X_1 + X_2$ is also a normal random variable with parameters $\mu_1 + \mu_2, \sigma_1^2 + \sigma_2^2$.

Table 2: Continuous random variables.

distribution	*range of* X	*density function* $f(x)$
uniform (α, β)	(α, β)	$\frac{1}{\beta-\alpha}$, $\alpha < \beta$
exponential (λ)	$[0, \infty)$	$\lambda e^{-\lambda x}$, $\lambda > 0$
standard normal $(0, 1)$	$(-\infty, \infty)$	$\frac{1}{\sqrt{2\pi}} e^{-x^2/2}$
normal (μ, σ^2)	$(-\infty, \infty)$	$\frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2}$, $\sigma > 0$
gamma $\Gamma(n, \lambda)$	$[0, \infty)$	$\frac{\lambda^n x^{n-1} e^{-\lambda x}}{\Gamma(n)}$, $\Gamma(n) = \int_0^\infty t^{n-1} e^{-t}\, dt$
Cauchy (α)	$(-\infty, \infty)$	$\frac{\alpha}{\pi(\alpha^2+x^2)}$, $\alpha > 0$
beta (p, q)	$[0, 1]$	$\frac{\Gamma(p+q)}{\Gamma(p)\Gamma(q)} x^{p-1}(1-x)^{q-1}$, $p, q > 0$
chi square $\chi^2(r)$	$[0, \infty)$	$\frac{1}{2^{r/2}\Gamma(r/2)} x^{\frac{r}{2}-1} e^{-\frac{x}{2}}$, $r > 0$
F-distribution $F_{m,n}$	$[0, \infty)$	$\frac{\Gamma((m+n)/2)}{\Gamma(m/2)\Gamma(n/2)} \left(\frac{m}{n}\right)^{m/2} \frac{x^{(m-2)/2}}{(1+(m/n)x)^{(m+n)/2}}$
t-distribution t_k	$(-\infty, \infty)$	$\frac{\Gamma((k+1)/2)}{\Gamma(k/2)} \frac{1}{\sqrt{k\pi}} \frac{1}{(1+x^2/k)^{(k+1)/2}}$
Rayleigh $R(\sigma)$	$[0, \infty)$	$\frac{xe^{-x^2/2\sigma^2}}{\sigma^2}$, $\sigma > 0$

Examples:

1. A spinner has three sectors—red, white, and blue—with sector areas 0.2, 0.7, and 0.1, respectively. Define a random variable X according to the rule $X = 1$ if the spinner points on red, $X = 2$ if it points on white, and $X = 3$ if it points on blue. The distribution of the discrete random variable X is displayed in the following table.

event	i	$Pr(X = i)$
red	1	0.2
white	2	0.7
blue	3	0.1

2. *Bernoulli random variable*: Let $A \subset \Omega$ be a fixed subset, with $Pr(A) = p$ for some $0 < p < 1$. Define the random variable X by $X(\omega) = 1$ for $\omega \in A$ and $X(\omega) = 0$ for $\omega \notin A$. Often it is said that a *success* occurs whenever $\omega \in A$ and a *failure* occurs otherwise. Then X is a Bernoulli random variable with $Pr(X = 1) = p$ and $Pr(X = 0) = 1 - p$. (Jakob Bernoulli, 1654–1705.)

3. *Binomial random variable*: Suppose that a die is thrown and that the occurrence of either a one or a six results in a "success". A single roll of the die constitutes a Bernoulli trial (Example 2) with probability of success $p = \frac{1}{3}$. The number of successes in 10 successive independent trials is a binomial random variable X with parameters $n = 10$ and $p = \frac{1}{3}$. In general, the number of successes X is a discrete random variable with possible values $0, 1, 2, \ldots, n$ and its distribution is given in Table 1.

4. A dart is thrown at a circular target of radius 1. Assume that the target is never missed and that any point on the target is as equally likely to be hit as any other point. Let X be the dart's distance from the center of the target. Since X can assume any value between 0 and 1, X is a continuous random variable. For $0 \le a < b \le 1$, $Pr(a < X < b) = Pr$(the dart lands in the annulus with radii a and b)$= \frac{1}{\pi}\times$(the area of the annulus with radii a and b)$= \frac{1}{\pi}(\pi b^2 - \pi a^2) = b^2 - a^2$.

5. *Hypergeometric random variable*: A total of n balls are selected from an urn containing N balls, of which m are red and $N - m$ are black. Let X be the number of red balls selected. Then X is a discrete random variable having the distribution

$$Pr(X = k) = \frac{\binom{m}{k}\binom{N-m}{n-k}}{\binom{N}{n}}, \quad 0 \le k \le m.$$

6. *Multinomial random variable*: Cast n identical balls into N labeled boxes in such a way that the probability that a ball ends up in box j is p_j, where $\sum_{j=1}^{N} p_j = 1$. Let X_j denote the number of balls in box j $(1 \le j \le N)$. For a vector $(x_1, x_2, \ldots, x_N)$ with $\sum_{j=1}^{N} x_j = n$, the probability that box 1 contains x_1 balls, box 2 contains x_2 balls,…, box N contains x_N balls is given by

$$\begin{aligned} Pr(X_1 = x_1, X_2 = x_2, \ldots, X_N = x_N) &= \frac{n!}{x_1!x_2!\ldots x_N!} p_1^{x_1} p_2^{x_2} \ldots p_N^{x_N} \\ &= \binom{n}{x_1\ x_2\ \ldots\ x_N} p_1^{x_1} p_2^{x_2} \ldots p_N^{x_N}, \end{aligned}$$

expressed using the multinomial coefficients (§2.3.2).

7. *Joint distribution*: Two fair coins are tossed once, resulting in four equally likely outcomes $\{(T,T), (T,H), (H,T), (H,H)\}$. Let the random variable X be the total number of heads observed, and let the random variable Y be the number of heads on the first coin minus the number of heads on the second coin. The joint probability distribution $\mu_{X,Y}$ is given by $Pr(X = 0, Y = 0) = Pr(X = 1, Y = -1) = Pr(X = 1, Y = 1) = Pr(X = 2, Y = 0) = \frac{1}{4}$. Thus $Pr(X = 0) = Pr(X = 2) = \frac{1}{4}$, $Pr(X = 1) = \frac{1}{2}$ and $Pr(Y = 1) = Pr(Y = -1) = \frac{1}{4}$, $Pr(Y = 0) = \frac{1}{2}$. Since $Pr(X = 0, Y = 0) = \frac{1}{4} \neq \frac{1}{8} = Pr(X = 0)\, Pr(Y = 0)$, the variables X and Y are not independent.

7.3.2 MEAN, VARIANCE, AND HIGHER MOMENTS

Definitions:

The ***mean*** (***expected value***) EX of a discrete random variable X is given by $EX = \sum_k k\, Pr(X = k)$.

The ***mean*** of a continuous random variable X with density function f is given by $EX = \int_{-\infty}^{\infty} xf(x)\, dx$.

The ***variance*** $\mathrm{Var}(X)$ of a random variable X is $\mathrm{Var}(X) = E((X - EX)^2)$.

The ***standard deviation*** of X is $\sqrt{\mathrm{Var}(X)}$.

The ***covariance*** $\mathrm{Cov}(X, Y)$ of two random variables X and Y is given by $\mathrm{Cov}(X, Y) = E((X - EX)(Y - EY))$.

The ***correlation*** $\rho_{X,Y}$ of two random variables X and Y is $\rho_{X,Y} = \dfrac{\mathrm{Cov}(X, Y)}{\sqrt{\mathrm{Var}(X)\ \mathrm{Var}(Y)}}$.

The ***kth moment*** of a random variable X is $E(X^k)$.

Facts:

1. The expected value EX of a random variable X measures the "weighted average" of X or the "center of gravity" of its distribution.

2. $E(X + Y) = EX + EY$.

3. $E(cX) = cEX$ for all constants c.

4. $E(c) = c$ for all constants c.

5. If X is a nonnegative integer random variable, then $EX = \sum\limits_{n=0}^{\infty} Pr(X > n)$.

6. If X is a nonnegative continuous random variable, then $EX = \int\limits_0^{\infty} Pr(X > x)\, dx$.

7. If X and Y are independent, then $E(XY) = (EX)(EY)$.

8. If g is a real-valued function and X is a discrete random variable, then $E(g(X)) = \sum_k g(k)\, Pr(X = k)$.

9. If g is an integrable real-valued function and X is continuous with density $f(x)$, then $E(g(X)) = \int g(t)f(t)\, dt$.

10. The variance $\mathrm{Var}(X)$ of a random variable X measures the "dispersion" of X about its expected value EX.

11. $\mathrm{Var}(X) \geq 0$; $\mathrm{Var}(X) = 0$ if and only if for some constant c, $Pr(X = c) = 1$.

12. $\mathrm{Var}(cX) = c^2\mathrm{Var}(X)$ for all constants c.

13. $\text{Var}(X+Y) = \text{Var}(X) + \text{Var}(Y) + 2\text{Cov}(X,Y)$.

14. $\text{Var}(X+Y) = \text{Var}(X) + \text{Var}(Y)$ if X and Y are independent.

15. $\text{Var}(X) = E(X^2) - (EX)^2$.

16. $\text{Cov}(X,Y) = 0$ if X and Y are independent. The converse is false. (Example 4.)

17. $\text{Cov}(X,Y) = E(XY) - (EX)(EY)$.

18. The correlation $\rho_{X,Y}$ is a scale-invariant measure of the degree of linear relationship between two random variables X and Y. Specifically, $\rho_{X,Y} = 1$ only when $Y = aX + b$ for some constants $a > 0$ and b. Similarly, $\rho_{X,Y} = -1$ only when $Y = aX + b$ for some constants $a < 0$ and b.

19. $|\rho_{X,Y}| \leq 1$.

20. *Bienaymé-Chebyshev's inequality*: $Pr(|X - EX| \geq t) \leq \frac{\text{Var}(X)}{t^2}$, for any value $t > 0$. (Irénée-Jules Bienaymé, 1796–1878 and Pafnuty Lvovich Chebyshev, 1821–1894.)

21. *Kolmogorov's inequality*: Suppose $X_1, X_2, \ldots, X_n$ are independent random variables, and let $S_k = X_1 + X_2 + \cdots + X_k$ for $1 \leq k \leq n$. Then for any value $t > 0$ the probability that $|S_k - ES_k| < t$ holds for all $k = 1, 2, \ldots, n$ is at least $1 - \frac{\text{Var}(S_n)}{t^2}$. (Andrey Nikolayevich Kolmogorov, 1903–1987.)

Examples:

1. The random variable X is the number of heads obtained in three tosses of a fair coin. It follows a binomial distribution (Table 1, §7.3.1), with $n = 3$ and $p = \frac{1}{2}$. Thus $Pr(X = 0) = \frac{1}{8}$, $Pr(X = 1) = \frac{3}{8}$, $Pr(X = 2) = \frac{3}{8}$, and $Pr(X = 3) = \frac{1}{8}$. Using the definition of expected value, $EX = \sum_k k\, Pr(X = k) = 0 \cdot \frac{1}{8} + 1 \cdot \frac{3}{8} + 2 \cdot \frac{3}{8} + 3 \cdot \frac{1}{8} = \frac{3}{2}$. In general, the mean of a binomial distribution with parameters n and p is np; see the corresponding entry in Table 3 of §7.3.3.

2. The variance of the discrete random variable X in Example 1 can be found using $\text{Var}(X) = E((X - EX)^2) = E((X - \frac{3}{2})^2) = (0 - \frac{3}{2})^2 \cdot \frac{1}{8} + (1 - \frac{3}{2})^2 \cdot \frac{3}{8} + (2 - \frac{3}{2})^2 \cdot \frac{3}{8} + (3 - \frac{3}{2})^2 \cdot \frac{1}{8} \cdot = \frac{3}{4}$. In general, the variance of a binomial distribution with parameters n and p is $np(1-p)$; see the corresponding entry in Table 3 of §7.3.3.

3. Suppose X is a Bernoulli random variable with parameter p, so $Pr(X = 0) = 1 - p$ and $Pr(X = 1) = p$. Then $EX = 0 \cdot (1-p) + 1 \cdot p = p$ and $\text{Var}(X) = E((X-p)^2) = (0-p)^2 \cdot (1-p) + (1-p)^2 \cdot p = p^2(1-p) + p(1-p)^2 = p(1-p)$. Also, $E(X^2) = 0^2 \cdot (1-p) + 1^2 \cdot p = p$ and using Fact 15 $\text{Var}(X) = E(X^2) - (EX)^2 = p - p^2 = p(1-p)$, as before.

4. *Covariance and independence*: In Example 7 of §7.3.1, $EX = 0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{2} + 2 \cdot \frac{1}{4} = 1$ and $EY = -1 \cdot \frac{1}{4} + 0 \cdot \frac{1}{2} + 1 \cdot \frac{1}{4} = 0$. Also, $E(XY) = -1 \cdot \frac{1}{4} + 0 \cdot \frac{1}{2} + 1 \cdot \frac{1}{4} = 0$. By Fact 17, $\text{Cov}(X,Y) = E(XY) - (EX)(EY) = 0 - 1 \cdot 0 = 0$. In this example, variables X and Y have zero covariance (and zero correlation); however (see §7.3.1, Example 7) they are not independent random variables.

5. The moments of the normal random variable X with parameters $\mu = 0$ and $\sigma = 1$ are $E(X^{2k}) = 1 \cdot 3 \cdots (2k-1)$ and $E(x^{2k-1}) = 0$ for $k \geq 1$.

6. A manufacturing plant produces ball bearings with an average diameter of 50 mm and a variance of 11 mm^2. Without any further information about the shape of the distribution of the diameters X, Fact 20 shows that the probability $Pr(|X - 50| \geq 8)$ of exceeding the nominal diameter by more than 8 mm is no more than $\frac{\text{Var}(X)}{8^2} = \frac{11}{64} = 0.172$. Thus, no more than 17.2% of the ball bearings produced can exceed the stated tolerance.

7. *Average-case algorithm analysis*: A simple algorithm for locating an item in an (unordered) list $A = [a_1, a_2, \ldots, a_n]$ is called a *linear search*; it sequentially examines each entry of list A and compares the given item *key* with each a_k until a match is found, or until the entire list is searched, in which case *key* is known not to be in the list. To obtain the average case complexity of this algorithm, suppose that *key* is known to occur in A and that it is equally likely (with probability $\frac{1}{n}$) to be at each of the n positions of A. If *key* is in fact located at position k of A, then k comparisons are required by the algorithm. The expected number of comparisons needed is thus $EX = \sum_{k=1}^{n} k\,Pr(X=k) = \sum_{k=1}^{n} k \cdot \frac{1}{n} = \frac{1}{n}\sum_{k=1}^{n} k = \frac{1}{n}\frac{n(n+1)}{2} = \frac{(n+1)}{2}$. Consequently, the average-case complexity of linear search is $O(n)$; see §1.3.3.

7.3.3 GENERATING FUNCTIONS

Definitions:

The ***probability generating function*** of a discrete random variable X is the function $\phi(t) = E(t^X) = \sum_k t^k\,Pr(X=k)$, defined for $|t| \le 1$.

The ***moment generating function*** of a discrete random variable X is the function $\psi(t) = E(e^{tX}) = \sum_k e^{tk}\,Pr(X=k)$, defined for all t such that $\psi(t)$ converges.

The ***moment generating function*** of a continuous random variable X with density f is the function $\psi(t) = E(e^{tX}) = \int e^{tx} f(x)\,dx$, defined for all t such that $\psi(t)$ converges.

The ***characteristic function*** (Fourier transform) of a discrete random variable X is $\chi(t) = E(e^{itX}) = \sum_k e^{itk}\,Pr(X=k)$, defined for all $t \in \mathcal{R}$.

The ***characteristic function*** of a continuous random variable X with density f is $\chi(t) = E(e^{itX}) = \int e^{itx} f(x)\,dx$, defined for all $t \in \mathcal{R}$.

Facts:

1. The expected value of a random variable X can be expressed in terms of the first derivative of its generating function: $EX = \phi'(1) = \psi'(0) = -i\chi'(0)$.

2. The variance of a random variable X can be expressed in terms of the first and second derivatives of its generating function: $\mathrm{Var}(X) = \phi''(1) + \phi'(1) - [\phi'(1)]^2 = \psi''(0) - [\psi'(0)]^2 = [\chi'(0)]^2 - \chi''(0)$.

3. $\frac{d^k}{dt^k}\phi(1) = E(X(X-1)(X-2)\dots(X-k+1))$.

4. $\frac{d^k}{dt^k}\psi(0) = E(X^k)$.

5. $\frac{d^k}{dt^k}\chi(0) = i^k E(X^k)$.

6. For any of the three types of generating functions defined, the generating function of the sum of independent random variables is the product of their respective generating functions.

Examples:

1. The binomial random variable with parameters n and p is the sum of n independent Bernoulli random variables with parameter p. The probability generating function for a Bernoulli random variable is $\phi(t) = E(t^X) = t^0(1-p) + t^1 p = q + pt$, where $q = 1-p$. By Fact 6 the probability generating function for a binomial random variable is $[\phi(t)]^n = (q+pt)^n$.

2. Table 3 shows the mean, variance, probability generating function, moment generating function, and characteristic function of several important discrete distributions. Here $q = 1-p$. An asterisk $(*)$ signifies that the entry is not available in simple form.

Table 3: Moments and generating functions for discrete distributions.

distribution	*mean*	*variance*	$\phi(t)$	$\psi(t)$	$\chi(t)$
Bernoulli $B(1,p)$	p	pq	$q+pt$	$q+pe^t$	$q+pe^{it}$
Binomial $B(n,p)$	np	npq	$(q+pt)^n$	$(q+pe^t)^n$	$(q+pe^{it})^n$
Poisson $P(\lambda)$	λ	λ	$e^{\lambda(t-1)}$	$e^{\lambda(e^t-1)}$	$e^{\lambda(e^{it}-1)}$
geometric $G(p)$	$\frac{1}{p}$	$\frac{q}{p^2}$	$\frac{pt}{1-qt}$	$\frac{pe^t}{1-qe^t}$	$\frac{pe^{it}}{1-qe^{it}}$
Pascal $NB(r,p)$	$\frac{r}{p}$	$\frac{rq}{p^2}$	$(\frac{pt}{1-qt})^r$	$(\frac{pe^t}{1-qe^t})^r$	$(\frac{pe^{it}}{1-qe^{it}})^r$
hypergeometric (N,m,n)	$\frac{mn}{N}$	$\frac{m(N-m)n(N-n)}{N^2(N-1)}$	$*$	$*$	$*$

3. Table 4 shows the mean, variance, moment generating function, and characteristic function of several important continuous distributions. An asterisk ($*$) indicates that the entry is not available.

Table 4: Moments and generating functions for continuous distributions.

distribution	*mean*	*variance*	$\phi(t)$	$\chi(t)$
uniform (α,β)	$\frac{\alpha+\beta}{2}$	$\frac{(\beta-\alpha)^2}{12}$	$\frac{e^{\beta t}-e^{\alpha t}}{t(\beta-\alpha)}$	$\frac{e^{i\beta t}-e^{i\alpha t}}{it(\beta-\alpha)}$
exponential (λ)	$\frac{1}{\lambda}$	$\frac{1}{\lambda^2}$	$\frac{\lambda}{\lambda-t}$	$\frac{\lambda}{\lambda-it}$
standard normal $(0,1)$	0	1	$e^{t^2/2}$	$e^{-t^2/2}$
normal (μ,σ^2)	μ	σ^2	$e^{\mu t+\frac{\sigma^2t^2}{2}}$	$e^{i\mu t-\frac{\sigma^2t^2}{2}}$
gamma $\Gamma(n,\lambda)$	$\frac{n}{\lambda}$	$\frac{n}{\lambda^2}$	$(\frac{\lambda}{\lambda-t})^n$	$(\frac{\lambda}{\lambda-it})^n$
Cauchy (α)	∞	∞	∞	$\frac{1}{\alpha^2}e^{-\alpha\|t\|}$
beta (p,q)	$\frac{p}{p+q}$	$\frac{pq}{(p+q)^2(p+q+1)}$	$*$	$*$
chi square $\chi^2(r)$	r	$2r$	$(1-2t)^{-r/2}$	$(1-2it)^{-r/2}$
F-distribution $F_{m,n}$	$\frac{n}{n-2}$	$\frac{2n^2(m+n-2)}{m(n-2)^2(n-4)}$	$*$	$*$
t-distribution t_k	0	$\frac{k}{k-2}$	$*$	$*$
Rayleigh $R(\sigma)$	$\sqrt{\frac{\pi}{2}}\sigma$	$2(1-\frac{\pi}{4})\sigma^2$	$*$	$*$

4. The moments of a binomial random variable X can be found from its moment generating function $\psi(t)=(q+pe^t)^n$. For example, $\psi'(t)=n(q+pe^t)^{n-1}(pe^t)$ and using Fact 1 produces $EX=\psi'(0)=n(q+p)^{n-1}p=np$.

5. From Table 4 the moment generating function for the exponential distribution with parameter λ is $\psi(t)=\frac{\lambda}{\lambda-t}$. Then $\psi'(t)=\frac{\lambda}{(\lambda-t)^2}$ and $\psi''(t)=\frac{2\lambda}{(\lambda-t)^3}$, giving $\psi'(0)=\frac{\lambda}{\lambda^2}=\frac{1}{\lambda}$ and $\psi''(0)=\frac{2\lambda}{\lambda^3}=\frac{2}{\lambda^2}$. By Facts 1 and 2, $EX=\psi'(0)=\frac{1}{\lambda}$ and $\mathrm{Var}(X)=\psi''(0)-[\psi'(0)]^2=\frac{2}{\lambda^2}-(\frac{1}{\lambda})^2=\frac{1}{\lambda^2}$.

7.4 DISCRETE PROBABILITY COMPUTATIONS

Many discrete probability computations are much less straightforward than may at first be imagined because of difficulties arising from the finiteness of computer arithmetic systems. Good algorithm design can usually avoid such problems.

7.4.1 INTEGER COMPUTATIONS

Enumeration of combinatorial objects, such as permutations and combinations, requires the computation of integer factorials. In practice, these factorials can only be computed as integers for small values. Since in most cases the factorials are not themselves the primary objective of the computation, potential numerical difficulties can be overcome by carefully designed recursive algorithms.

Definitions:

The N-bit ***binary representation*** of the positive integer n is $(b_{N-1}b_{N-2}\dots b_1b_0)_2$ where $b_i \in \{0,1\}$ and $n = \sum_{i=0}^{N-1} b_i 2^i$. (See §4.1.3.) Each b_i is a ***binary digit*** (***bit***).

The ***two's complement*** representation of the signed integer n is $(b_{N-1}b_{N-2}\dots b_1b_0)_{2'}$ where $n = -b_{N-1}2^{N-1} + \sum_{i=0}^{N-2} b_i 2^i$.

Integer ***wraparound*** is the phenomenon of adding 1 to the largest representable integer and obtaining the smallest representable integer.

Facts:

1. Signed integers are usually represented in a computer as two's complement binary words of a fixed wordlength; commonly 8, 16, or 32 bits are used.

2. A two's complement integer using N-bit words is interpreted by treating the most significant bit as a coefficient of 2^{N-1}.

3. The range of representable integers in N-bit two's complement is from $-2^{N-1} = (10\dots00)_{2'}$ to $2^{N-1} - 1 = (01\dots11)_{2'}$. Arithmetic operations can generate no carries beyond this range.

4. Integer wraparound is a consequence of Fact 3 since (in regular binary arithmetic) $(01\dots11)_2 + (00\dots01)_2 = (10\dots00)_2$. Some systems have integer range checking available to avoid the effect of wraparound.

5. Permutations and combinations (§2.3) are usually expressed in terms of integer factorials.

6. Binomial coefficients (§2.3.2) can be computed using integer arithmetic provided the result is within the range being used. Algorithm 1 breaks the computation of a binomial coefficient into a recursive loop using $\binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n(n-1)\dots(n-k+1)}{k(k-1)\dots1} = \left(\frac{n}{1}\right)\left(\frac{n-1}{2}\right)\dots\left(\frac{n+1-k}{k}\right)$ and the result $\binom{n}{k} = \binom{n}{n-k}$. (See §2.3.2, Fact 7.)

Algorithm 1: **Integer computation of binomial coefficients.**

```
input: positive integers $n, k$
output: $b = \binom{n}{k}$
if $2k > n$ then $k := n - k$
$b := 1$
for $i := 1$ to $k$
    $b := [b \cdot (n + 1 - i)]$ div $i$
```

7. By doing the multiplication before the integer division in Algorithm 1, the numerator necessarily has the appropriate factors to ensure an exact integer result.

Examples:

1. For $N = 8$, 16, and 32 bits, the two's complement binary integer ranges are given in the following table.

N	*minimum value*	*maximum value*
8	-128	127
16	-32768	32767
32	-2147483648	2147483647

2. For $N = 8$, the integer 86 has the two's complement representation $(01010110)_{2'}$ and the integer -86 has the two's complement representation $-128 + 42 = (10101010)_{2'}$.

3. For 8-bit integers, the effect of integer wraparound is shown by $127 + 1 = -128$. Similarly, we would have $64 \times 2 = -128$.

4. For 8-bit two's complement integers, only $1!, 2!, 3!, 4!, 5!$ can be computed correctly. Subsequent factorials would generate integer answers—but wrong ones. In particular, 6! would evaluate to -48. Namely, the 8-bit two's complement representation of $5! = 120$ is 01111000 and $6 = 00000110$ so that, with no carries to the left of the 8th bit, $6! = 6 \times 5!$ is represented by the sum of 11100000 and 11110000 (which are respectively 01111000 shifted 2 and 1 places left.) This sum (again without carries to the left of the leading bit) is 11010000, which represents $(-128) + 64 + 16 = -48$.

5. Using 16-bit integers with wraparound, the binomial coefficient $\binom{12}{8}$ cannot be computed directly from its definition since neither 12! nor 8! can be computed correctly. Thus Algorithm 1 finds instead $\binom{12}{4} = \binom{12}{8}$ since $2 \times 8 > 12$. This is computed as $\left(\frac{12}{1}\right)\left(\frac{11}{2}\right)\left(\frac{10}{3}\right)\left(\frac{9}{4}\right)$, with each multiplication being performed before its associated division: $(12/1)$ is multiplied by 11, divided by 2, multiplied by 10, divided by 3, multiplied by 9, and divided by 4. This produces the intermediate results 12, 132, 66, 660, 220, 1980, 495, so that the correct final result is obtained without any intermediate computation exceeding the integer range.

7.4.2 FLOATING-POINT COMPUTATIONS

To compute discrete probabilities (e.g., binomial probabilities), careful attention must be given to the underlying floating-point computation model and its properties.

Definitions:

Let F be the set of numbers representable in a particular floating-point system, with Ω the largest positive number in F and ω the smallest positive number in F.

The floating-point arithmetic operations in F are denoted by $\oplus, \ominus, \otimes, \oslash$ when it is necessary to distinguish them from their real counterparts $+, -, \times, /$.

The number x is represented in the computer in binary ***floating-point*** form by the approximation $x \approx \pm f \times 2^E$ where the ***fraction*** or ***mantissa*** f is a binary fraction of fixed length and the ***exponent*** E is an integer within a fixed range. Usually the floating point representation is ***normalized*** so that $f \in [1, 2)$.

Floating-point arithmetic is subject to ***roundoff error***, the error introduced by abbreviating the representation of a number or an arithmetic result to a finite wordlength.

The usual measure of error for floating-point computation is ***relative error***, which is given for an approximation x^* to a quantity x by $\dfrac{|x^* - x|}{|x|} \approx \dfrac{|x^* - x|}{|x^*|}$.

A ***floating-point operation*** (or ***flop***) is any arithmetic operation performed using floating-point arithmetic.

Overflow results from a floating-point operation where the magnitude of the result is too large for the available range of the floating-point system being used.

Underflow results from a floating-point operation where the magnitude of the result is too small for the available range of the floating-point system being used.

The ***machine unit*** μ of a floating-point system is the smallest positive number that can be added to 1 and produce a result recognized in the machine as greater than 1: namely, $\mu = \min\{x \in F \mid 1 \oplus x > 1\}$.

Facts:

1. Roundoff errors are propagated in subsequent computations.

2. The two expressions given for relative error are often used interchangeably.

3. Overflow and underflow result from the finite range of available exponents. The limits of these ranges and the details of the implementation vary with both the hardware and software being used. See [IE08] for the most common implementations.

4. Usually an overflow condition terminates a program, while underflow results are normally replaced by 0.

5. Because of the finite mantissa length (and independent of the rounding rule), most axioms of the real number system fail for floating-point arithmetic [St74]. The following table summarizes similarities and differences between the real numbers $\mathcal{R}$ and the floating-point system F. The second column of the table describes the property, assuming $a, b, c \in \mathcal{R}$. If the property fails in F, a brief reason for the failure is also given.

property	*description in $\mathcal{R}$*	*valid in F?*
closure +	$a + b \in \mathcal{R}$	NO: overflow
closure ×	$a \times b \in \mathcal{R}$	NO: overflow
commutativity	$a + b = b + a,\ a \times b = b \times a$	YES
associativity +	$(a + b) + c = a + (b + c)$	NO: $a = 1$, $b = c = \frac{\mu}{2}$
special case	$(a + b) - a = b$	NO: $a = 1$, $b = \frac{\mu}{2}$
associativity ×	$(a \times b) \times c = a \times (b \times c)$	NO: roundoff, overflow, or underflow
distributive law	$a \times (b + c) = (a \times b) + (a \times c)$	NO: roundoff, overflow, or underflow
existence of zero	$(\exists\, 0)\ \ a + 0 = a$	YES
unique negative	$\exists!\,(-a)\ \ a + (-a) = 0$	NO: $[-(1 \oplus \mu) \otimes a] \oplus a = 0$ if $\mu \times a < \omega$
existence of one	$(\exists\, 1)\ \ a \times 1 = a$	YES
zero divisors	$a \times b = 0 \Rightarrow a = 0$ or $b = 0$	NO: $a \otimes b = 0 \Rightarrow a < \sqrt{\omega}$ or $b < \sqrt{\omega}$
total ordering	$a < b$ or $a = b$ or $a > b$	YES
order-preservation	$a > b \Rightarrow a + c > b + c$	NO: roundoff
special case	$x > 0 \Rightarrow 1 + x > 1$	NO: $x < \mu$

6. In the previous table, most of the properties that fail in F hold approximately—at least for arguments of the same sign. These failures are not critical to most computations, but they can be important for computations such as summing sets of numbers and evaluating binomial probabilities.

7. The existence of the machine unit μ ensures that some of the order properties of $\mathcal{R}$ will not carry over to F.

8. The machine unit μ is not the same as the smallest representable positive number ω in F.

9. The relative error in subtraction is essentially unbounded due to cancellation.

10. IEEE arithmetic is required to deliver the same result as if rounding were performed on the infinite precision computation assuming that the data are exact.

11. A sum of terms of the same sign should generally be summed from smallest to largest.

12. Improved accuracy in computing a summation is possible by regarding the partial sums as members of a (reduced) list of summands and always adding the two smallest terms in the current list. However, the overhead would be prohibitive in most cases.

13. Special care must be taken in computing a summation if its terms are computed recursively, since the smallest term can underflow.

14. There is no completely reliable method for summing terms of mixed sign.

15. For alternating series, special transformations such as Euler's method can be used [BuTu92, Chapter 1].

16. Algorithm 2 computes the cumulative sum of binomial probabilities (§7.3.1) using the definition $B(N,p\,;k) = \sum_{i=0}^{k} \binom{N}{i} p^i (1-p)^{N-i}$.

Algorithm 2: **Recursive computation of binomial probabilities.**

```
input: positive integers $N, k$; real number $p$
output: $s = B(N,p\,;k)$
$q := 1 - p$
$t := q^N$
$s := t$
for $i := 1$ to $k$
    $t := t * \left(\frac{p}{q}\right) * \frac{(N+1-i)}{i}$
    $s := s + t$
```

17. Algorithm 2 will only work for small values of N.

18. If k is not too large, Algorithm 2 does in fact sum terms from smallest to largest.

19. To compute $B(N,p\,;k)$ for large values of k, use the fact that $B(N,p\,;k) = 1 - B(N,1-p\,;N-k-1)$ and then apply Algorithm 2.

20. If q^N underflows to 0, then Algorithm 2 returns 0 for all values of k.

21. Algorithm 3 gives an alternative way to calculate the individual binomial probability term $\binom{N}{r} p^r (1-p)^{N-r}$. It computes the logarithm of each factor recursively and then exponentiates this at the end.

Algorithm 3: **Logarithmic computation of binomial probability terms.**

```
input: positive integers $N, r$; real number $p$
output: $b = \binom{N}{r} p^r (1-p)^{N-r}$
$q := 1 - p$
$t := r * \ln p + (N - r) \ln q$
for $i := 1$ to $r$
  $t := t + \ln(N + 1 - i) - \ln i$
$b := e^t$
```

22. Algorithm 3 must be safeguarded to ensure that e^t underflows to 0 for large negative arguments t.

23. Using logarithms is a frequently applied technique for computing products of many factors with widely varying magnitudes. It is one step along the way toward using the symmetric level-index scheme for number representation and arithmetic [ClOlTu89].

Examples:

1. *Summations*: If the first 2^{24} terms of the harmonic series are summed using IEEE single precision floating-point arithmetic, both forward and backward, then the sums differ by approximately 11%. Specifically, $\left(\cdots\left(\left(1 \oplus \frac{1}{2}\right) \oplus \frac{1}{3}\right) \oplus \cdots \oplus 2^{-24}\right) \approx 15.40$, while summing the same terms from right-to-left yields 17.23.

2. *Binomial probabilities*: The computation of binomial probabilities is thoroughly discussed in Section 2.6 of [St74] with reference to the specific case where $N = 2000$, $k = 200$, and $p = 0.1$. Using Algorithm 2 in this case gives the initial value $t = 0$ and therefore the final result is $s = 0$. The true value of the final probability is approximately 0.5.

3. If the final term in Example 2 is computed in IEEE single precision, the binomial coefficient itself would overflow. It is certainly greater than 10^{200}. Also, both $(0.1)^{200}$ and $(0.9)^{1800}$ would underflow. However the true value of this term is around 0.03.

7.5 RANDOM WALKS

Random walks are special stochastic processes whose applications include various models of particle motion, covering topics as diverse as crystallography, gambling, stock markets, biology, genetics, astronomy, and statistical sampling of large graphs. This section examines an important special class of random walks, sometimes referred to as lattice random walks, whose trajectories are generated by the summation of independent and identically distributed discrete random variables.

7.5.1 GENERAL CONCEPTS

Definitions:

A ***stochastic process*** is a collection of random variables, typically indexed by time (discrete or continuous).

A ***d-dimensional random walk*** is a stochastic process on the integer lattice $\mathcal{Z}^d$ whose ***trajectories*** are defined by an initial position $S_0 = a$ and the sequence of sums $S_n = a + X_1 + X_2 + \cdots + X_n$, $n \geq 1$, where the displacements $X_1, X_2, \ldots$ are independent and identically distributed random variables on $\mathcal{Z}^d$.

A random walk is ***simple*** if the values X_i are restricted to the $2d$ points of $\mathcal{Z}^d$ of unit Euclidean distance from the origin. (That is, the random walk proceeds at each time step to a point one unit from the current point along some coordinate axis.) A ***symmetric*** random walk is a simple walk in which the $2d$ values of X_i have the same probability.

Random walks that return to the initial position with probability 1 are ***recurrent***; otherwise they are ***transient***.

An ***absorbing boundary*** is a point or a set of points on the lattice that stops the motion of a random walk whose trajectory comes into contact with it. A ***reflecting boundary*** is a point or a set of points that redirects the motion of a random walk. Both are special cases of an ***elastic*** boundary, which stops or redirects the motion depending on some given probability.

The ***gambler's ruin problem*** is a simple one-dimensional random walk with absorbing boundaries at values 0 and b. It colorfully illustrates the fortunes of a gambler, who starts with a dollars and who at each play of a game has a fixed probability of winning one dollar. The game ends once the gambler has either amassed the amount $S_n = b$ or goes broke $S_n = 0$.

For $k \in \mathcal{Z}^d$, the ***first passage time*** T_k into point k is the first time at which the random walk reaches the point k: namely, $T_k = \min\{i \geq 1 \mid S_i = k\}$. More generally, the ***hitting time*** T_A for entering set $A \subseteq \mathcal{Z}^d$ is the first time at which the random walk reaches some point in set A: namely, $T_A = \min\{i \geq 1 \mid S_i \in A\}$.

The following is the ***basic initial problem*** of random walks.

- For $k \in \mathcal{Z}^d$, find $Pr(S_n = k)$, the probability that a "particle", executing the random walk and starting at point a at time 0, will be at point k at time n.

The following are ***first passage time problems***.

- Find the probability $Pr(T_k = n)$ that, starting at point a at time 0, the first visit to point k occurs at time n.
- Find the probability $Pr(T_A = n)$ that, starting at point a at time 0, the first visit to A occurs at time n; characterize S_{T_A}, the point at which A is first visited.

Other classical problems in random walks include

- *Range problem*: Find or approximate the probability distribution and/or the mean of the number of distinct points visited by a random walk up to time n.
- *Occupancy problem*: Find or approximate the probability distribution and/or the mean of the number of times a given point or a set of points has been visited up to time n.
- *Boundary problem*: Address all previous problems under absorbing, reflecting, and/or elastic boundary conditions.

Examples:

1. *Coin tossing*: Tossing a coin n times can be viewed as a one-dimensional random walk ($d = 1$) on the integers $\mathcal{Z}$. This walk begins at the origin ($a = 0$) with $X_i = 1$ if the result of the ith toss is a Head and $X_i = -1$ if the result of the ith toss is a Tail. Since each step X_i is of unit length, this is a *simple* one-dimensional random walk. If the tosses are independent events, then $Pr(X_i = 1) = p$ and $Pr(X_i = -1) = 1 - p$ holds for all i, where $0 < p < 1$. The random variable S_n is the cumulative number of Heads minus the cumulative number of Tails in n tosses. The walk is symmetric if $p = \frac{1}{2}$. A return to the origin means that $S_n = 0$: that is, the number of Heads and Tails have equalized after n tosses.

2. *Gambler's ruin*: A gambler repeatedly plays a game of chance, in which a dollar is won at each turn with probability p and a dollar is lost with probability $1 - p$. For example, suppose the gambler starts with 90 dollars, and stops whenever his current fortune is 0 (a ruin) or 100 (a positive net gain of 10 dollars). What is the gambler's ultimate probability of being ruined? Of success? On average how many expected plays does it take for the game to be over? What is the expected net gain for the gambler? If $p = 0.5$ the answers are 0.1, 0.9, 900, and 0 respectively. If $p = 0.45$ they are 0.866, 0.134, 765.6, and -76.6 respectively. (See §7.5.2, Example 4.)

7.5.2 ONE-DIMENSIONAL SIMPLE RANDOM WALKS

A number of results are known for random walks in one dimension that take a succession of unit steps (in either the positive or negative direction).

Definitions:

The ***one-dimensional simple random walk*** (see §7.5.1) corresponds to a particle moving randomly on the set $\mathcal{Z}$ of integers. It begins at the origin at time 0 and at each time $1, 2, \ldots$ thereafter, moves either one step up (right) with probability p, or one step down (left) with probability $1 - p$. This random walk is ***symmetric*** when $p = \frac{1}{2}$.

The ***trajectory*** of a one-dimensional simple random walk is described by $S_0 = 0$ and $S_n = X_1 + X_2 + \cdots + X_n$, $n \geq 1$, where the X_i are independent and have a Bernoulli distribution (§7.3.1), with $Pr(X_i = 1) = p$ and $Pr(X_i = -1) = q = 1 - p$ for $p \in (0, 1)$.

Suppose a trajectory is graphically represented by plotting S_n as a function of n, so that the point (n, k) corresponds to $S_n = k$. Linking successive points with straight lines produces a ***path*** between points. Define $N(n, k)$ to be the number of paths from $(0, 0)$ to (n, k).

In a random walk starting at $S_0 = a > 0$ with absorbing boundaries at 0 and $b > a$:

- q_a is the probability that the random walk will be absorbed at 0;
- p_a is the probability that the random walk will be absorbed at b;
- D_a is the time until absorption.

Facts:

1. *Reflection principle*: Let $n_2 > n_1 \geq 0$, $k_1 > 0$, $k_2 > 0$. The number of paths from (n_1, k_1) to (n_2, k_2) that touch or cross the x-axis equals the number of paths from $(n_1, -k_1)$ to (n_2, k_2).

2. $N(n, k) = \binom{n}{(n+k)/2}$, if $\frac{n+k}{2}$ is an integer in $\{0, 1, \ldots, n\}$; $N(n, k) = 0$ otherwise.

3. If $n \geq 1$ is fixed and $-n \leq k \leq n$, then $Pr(S_n = k) = N(n,k)p^{\frac{1}{2}(n+k)}q^{\frac{1}{2}(n-k)}$.

4. *Ballot theorem*: For $k > 0$, the number of paths from $(0,0)$ to (n,k) that do not return to or cross the x-axis is $\frac{k}{n}N(n,k)$.

5. For $n \geq 1$, the first return time T_0 to the origin satisfies

- $Pr(T_0 > n) = E(\frac{|S_n|}{n})$;
- $Pr(T_0 = 2n) = \frac{1}{2n-1}\binom{2n}{n}p^n q^n$;
- $Pr(T_0 > 2n) = Pr(S_{2n} = 0) = \binom{2n}{n}2^{-2n}$, if the walk is symmetric.

6. *Recurrent walks*: $Pr(T_0 < \infty) = 1$ (the walk is recurrent) if and only if $p = q = \frac{1}{2}$. In this case $E(T_0) = \infty$.

7. For $k \neq 0$ and $n > 0$, $Pr(T_k = n) = \frac{|k|}{n}\, Pr(S_n = k)$.

8. For $k > 0$ and $n > 0$, the maximum value $M_n = \max\{S_0, S_1, \ldots, S_n\}$ satisfies

- $M_n \geq k$ if and only if $T_k \leq n$;
- $Pr(M_n \geq k) = Pr(S_n = k) + \sum\limits_{i \geq k+1} [1 + (\frac{q}{p})^{i-k}]\, Pr(S_n = i)$;
- $Pr(M_n = k) = Pr(S_n = k) + Pr(S_n = k+1)$, if the walk is symmetric.

9. *Arc sine laws*: Let W_n be the number of times among $\{0, 1, \ldots, n\}$ at which a random walk is positive and let L_n be the time of the last visit to 0 up to time n. For a symmetric random walk,

- $Pr(W_{2n} = 2k) = Pr(L_{2n} = 2k) = Pr(S_{2k} = 0)\, Pr(S_{2n-2k} = 0)$;
- as $n \to \infty$, $Pr(\frac{W_{2n}}{2n} \leq x) \approx \frac{2}{\pi} \arcsin \sqrt{x}$, for $x \in [0,1]$.

10. *Gambler's ruin problem*: In this random walk with absorbing boundaries (§7.5.1), q_a is the probability of the gambler (having an initial capital of a) being ruined and p_a is the probability of eventually winning (achieving a total of b). Facts 11–17 refer to the gambler's ruin problem.

11. If $p \neq q$, $q_a = \frac{(q/p)^b - (q/p)^a}{(q/p)^b - 1}$ and $p_a = 1 - q_a$.

12. If $p = q = \frac{1}{2}$, $q_a = 1 - \frac{a}{b}$ and $p_a = \frac{a}{b}$.

13. The expected gain in the gambler's ruin problem is $b(1 - q_a) - a$, which is 0 if and only if $p = q = \frac{1}{2}$.

14. $Pr(D_a = n) = b^{-1}2^n p^{(n-a)/2} q^{(n+a)/2} \sum\limits_{k=1}^{b-1} \cos^{n-1} \frac{\pi k}{b} \sin \frac{\pi k}{b} \sin \frac{\pi a k}{b}$.

15. If $p \neq q$, $E(D_a) = \frac{a}{q-p} - \frac{b}{q-p} \frac{1-(q/p)^a}{1-(q/p)^b}$.

16. If $p = q = \frac{1}{2}$, $E(D_a) = a(b-a)$.

17. *Limiting case of the gambler's ruin problem*: When $b = \infty$,

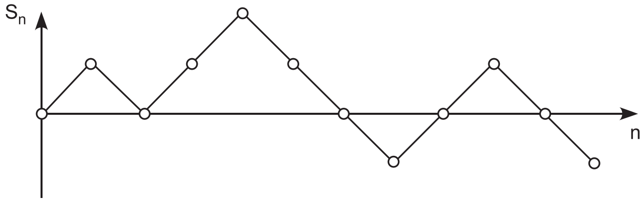
- $q_a = (\frac{q}{p})^a$ if $p > q$, and $q_a = 1$ otherwise;
- $Pr(D_a = n) = 2^n p^{(n-a)/2} q^{(n+a)/2} \int_0^1 \cos^{n-1} \pi x \sin \pi x \sin \pi a x \, dx$
  $= \frac{a}{n}\binom{n}{(n+a)/2} p^{\frac{1}{2}(n-a)} q^{\frac{1}{2}(n+a)}$;
- if $p < q$, $E(D_a) = \frac{a}{q-p}$;
- if $p = q = \frac{1}{2}$, $E(D_a) = \infty$.

18. *Random walks with one reflecting boundary*: Consider a random walk starting at $S_0 = a \geq 0$ with a reflecting boundary at 0.

- The position at time $n \geq 1$ is given by $S_n = \max\{0, S_{n-1} + X_n\}$.
- When $p < q$ and as $n \to \infty$, there is a stationary distribution for the random walk, coinciding with the distribution of $M = \sup_{i \geq 0} S_i$, and given by $Pr(M = k) = (1 - \frac{p}{q})(\frac{p}{q})^k$ for all $k \geq 0$.

Examples:

1. A graphical representation of the trajectory for a one-dimensional simple random walk is shown in the following figure. Here $T_0 = 2$ and $T_2 = 4$; $M_3 = 1$ and $M_4 = 2$; $W_7 = 4$; and $L_7 = 6$.



2. The ballot theorem takes its name from the following problem. Suppose that, in a ballot, candidate A scores x votes and candidate B scores y votes, $x > y$. What is the probability that, during the ballot, A is always ahead of B? By Fact 4, the answer is $\frac{x-y}{x+y}$. As an illustration, if $\frac{x}{x+y} = 0.52$, this probability is 0.04.

3. How much time does a symmetric random walk spend to the left of the origin? Contrary to intuition, with non-negligible probability, the fraction of time spent to the left (or to the right) of the origin is near 0 or 1, but not near $\frac{1}{2}$.

For example, when n is large, Fact 9 shows that the probability a symmetric random walk spends at least 97.6% of the time to the left of the origin is approximately $0.1 = \frac{2}{\pi} \arcsin \sqrt{0.024}$. Symmetrically, there is a 0.1 probability that it spends at least 97.6% of the time to the right of the origin. Altogether, with probability 0.2 a symmetric random walk spends at least 97.6% of the time entirely on one side of the origin.

4. *Gambler's ruin*: Suppose that the probability of winning one dollar is $p = 0.45$, so $q = 0.55$. A gambler begins with an initial stake of $a = 90$ and will quit whenever the current winnings reach $b = 100$. Using Fact 11, the probability of ruin (i.e., losing the entire original stake) is

$$q_a = \frac{(11/9)^{100} - (11/9)^{90}}{(11/9)^{100} - 1} \approx 0.866.$$

The expected net gain is, by Fact 13, $b(1 - q_a) - a = 100(0.134) - 90 = -76.6$. The average duration (number of plays of the game) is found from Fact 15 to be 765.6 plays. Surprisingly, even though the probability p of winning is only slightly less than 0.5 and the gambler starts within close reach of the desired goal, the gambler can expect to be ruined with high probability and the average number of plays of the game is large.

5. The average duration of a fair game in the gambler's ruin problem is considerably longer than would be naively expected. When one player has one dollar and the adversary 1,000 dollars, Fact 16 shows that the average duration is 1,000 trials.

7.5.3 GENERALIZED RANDOM WALKS

Two generalizations of one-dimensional random walks are covered here. In the first case, a one-dimensional walk is now allowed to be based on an arbitrary (as opposed to

Bernoulli) distribution. In the second case, a symmetric random walk is considered in higher dimensions.

Definitions:

In a one-dimensional random walk on $\mathcal{Z}$ starting at $S_0 = a > 0$ with a given boundary $b > a$, let u_a be the probability that the particle will arrive at some position which is less than or equal to 0 before reaching any position greater than or equal to b.

Let R_n be the number of distinct points visited by a random walk up to time n.

Facts:

1. If $X_1, X_2, \ldots$ are arbitrarily distributed independent random variables, many basic qualitative laws are preserved for one-dimensional walks.

- In the case of two absorbing boundaries, the particle will reach one of them with probability 1.
- In the case of a single absorbing boundary at 0, if $E(X_i) \leq 0$ then the particle will reach 0 with probability 1.
- An unrestricted walk with $E(X_i) = 0$ and $\text{Var}(X_i) < \infty$ will return to its initial position with probability 1, and the expected return time is infinite.

2. *General ruin problem*: Assume that at each step the particle has probability p_k to move from any point i to $i + k$, where $k \in \mathcal{Z}$. The particle starts from position a.

- $u_a = 1$ if $a \leq 0$, and $u_a = 0$ if $a \geq b$.
- For $0 < a < b$, $u_a = \sum\limits_{i \in \mathcal{Z}} u_i p_{i-a}$. This corresponds to a system of $b - 1$ linear equations in $b - 1$ unknowns that has a unique solution.

3. *Local central limit theorem*: For a d-dimensional symmetric (simple) random walk,

- $|\, Pr(S_n = k) - 2(\frac{d}{2\pi n})^{d/2} e^{-\frac{d|k|^2}{2n}} \,| \leq O(n^{-(d+2)/2})$;
- $|\, Pr(S_n = k) - 2(\frac{d}{2\pi n})^{d/2} e^{-\frac{d|k|^2}{2n}} \,| \leq |k|^{-2} O(n^{-d/2})$.

4. *Pólya's theorem*: For the symmetric random walks in 1 or 2 dimensions, there is probability 1 that the walk will eventually return to its initial position (recurrent random walk). In dimension $d \geq 3$ this probability is strictly less than 1. (George Pólya, 1887–1985.)

5. For symmetric random walks in $d = 3$ dimensions, the probability of an eventual return to the initial position is approximately 0.34 and the expected number of returns is approximately 0.53. The following table gives the approximate return probabilities $Pr(T_0 < \infty)$ for dimensions $d \leq 10$.

d	$Pr(T_0 < \infty)$
3	0.341
4	0.193
5	0.135
6	0.105
7	0.0858
8	0.0729
9	0.0634
10	0.0562

6. *Range problems*: As $n \to \infty$,

- if $d = 1$, $E(R_n) \approx (\frac{8n}{\pi})^{1/2}$;
- if $d = 2$, $E(R_n) \approx \frac{\pi n}{\log n}$;
- if $d \geq 3$, $E(R_n) \approx c_d n$ for some constant c_d.

Example:

1. *Absorbing boundaries*: A particle starts at position $a \in \{0, 1, 2, 3, 4\}$ on a line and with equal probabilities moves one or two positions, either to the right or left. Upon reaching a position $x \leq 0$ or $x \geq 4$, the particle is stopped. This is a form of the general ruin problem with $p_{-2} = p_{-1} = p_1 = p_2 = \frac{1}{4}$. We are interested in the probability u_a of absorption at position $x \leq 0$, given that the particle starts at position a. Using Fact 2, $u_0 = 1$, $u_4 = 0$ and u_1, u_2, u_3 satisfy the following equations:

$$\begin{aligned} u_1 &= \tfrac{1}{2} + \tfrac{1}{4}u_2 + \tfrac{1}{4}u_3 \\ u_2 &= \tfrac{1}{4} + \tfrac{1}{4}u_1 + \tfrac{1}{4}u_3 \\ u_3 &= \tfrac{1}{4}u_1 + \tfrac{1}{4}u_2. \end{aligned}$$

Solving this linear system produces the unique solution $u_1 = \frac{7}{10}$, $u_2 = \frac{1}{2}$, $u_3 = \frac{3}{10}$. Intuitively, these are reasonable values since starting at the middle position $a = 2$ it should be equally likely for the particle to be absorbed at either boundary; starting at position $a = 1$ there should be a greater chance of absorption at the left boundary (probability $\frac{7}{10}$) than at the right boundary (probability $1 - \frac{7}{10} = \frac{3}{10}$).

7.5.4 APPLICATIONS OF RANDOM WALKS

Random walk methodology is central to a number of diverse problem settings. This section describes several important applications. Additional examples are found in [BaNi70], [Be93], and [We94].

Examples:

1. *Biological migration*: The name "random walk" first appears in a query sent by Karl Pearson (1857–1936) to the journal *Nature* in 1905. Pearson's problem refers to a walk in the plane, with successive steps of length $l_1, l_2, \ldots$ at angles $\Theta_1, \Theta_2, \ldots$ with respect to the x-axis, the Θ_i being chosen randomly. The problem is to find, after some fixed time, the probability distribution of the distance from the initial position. The question was motivated by a theory of biological migration which Pearson developed at that time, but soon discarded. Nevertheless, Pearson's random walk was born and it has since been applied to many biological models.

2. *Biology*: Other, more recent, examples of random walk applications include DNA sequencing in genetics, bacterial migration in porous media, and molecular diffusion. In the latter example, diffusion of molecules occurs as a result of the thermal energy of the molecules. The motion of the molecules, perturbed through interactions with other molecules, is then modeled as a random walk. See [Be93] for further details.

3. *Physical sciences*: There are many applications in the physical sciences, including the classical Scher-Montroll model of electrical transport in amorphous semiconductors (a continuous-time random walk model), models of diffusion on tenuously connected structures such as percolation clusters, inference of molecular structure from data collected in x-ray scattering experiments, configurational statistics of polymers, and reaction kinetics in confined geometries. Details can be found in [BaNi70] and [We94].

4. *Sequential sampling*: A major application of random walks in statistics is in connection with Wald's theory of sequential sampling. In this context, the X_i represent certain characteristics of samples or observations. Measurements are taken as long as the random walk remains within a given region. Termination with acceptance or rejection of the appropriate hypothesis occurs depending on which part of the boundary is reached.

5. *Stock prices*: One of the early applications of computers in economics was to analyze economic time series and, in particular, the behavior of stock market prices over time. It first came as a surprise when Kendall found in 1953 that he could not identify any predictable patterns in stock prices. However, it soon became apparent that random price movements indicated a well-functioning or efficient market and that a random walk could be used as a model for the underlying market. See [Ma90]. In fact, at the beginning of this century, Bachelier had already developed a diffusion model for the stock market. Other macroeconomic time series have also been modeled using random walks.

6. *Astronomy*: The problem of the mean motion of a planet in the presence of perturbations due to other planets has a very long history (Lagrange). Statistical properties of perturbed orbits can be analyzed with the help of Pearson's random walk model. The escape of comets from the solar system has also been modeled as a random walk among energy states. Details are provided in [BaNi70].

7.6 SYSTEM RELIABILITY

System reliability involves the study of the overall performance of systems of interconnected components. Examples of such systems are communication, transportation, and electrical power distribution systems, as well as computer networks.

7.6.1 GENERAL CONCEPTS

Definitions:

Suppose a given system is composed of a set $N = \{1, 2, \ldots, n\}$ of failure-prone ***components***. At any instant of time, each component is found in one of two ***states***: either ***operating*** or ***failed***.

The ***reliability*** of component i is the probability p_i that component i is operating at a given instant of time. The ***unreliability*** (or failure probability) of component i is $q_i = 1 - p_i$.

At any instant of time, the system is found in one of two ***states***: ***operating*** or ***failed***.

The ***structure function*** ϕ is a binary-valued function defined on all subsets $S \subseteq N$. Specifically, $\phi(S) = 1$ if the system operates when all components in S operate and all components of $N - S$ fail; otherwise $\phi(S) = 0$.

The structure function ϕ is ***monotone*** if $S \subseteq T \Rightarrow \phi(S) \leq \phi(T)$. In words, monotonicity means that the addition of more operating components to an already functioning system cannot result in system failure.

The structure function ϕ is ***nontrivial*** if $\phi(\emptyset) = 0$ and $\phi(N) = 1$.

A ***coherent*** system (N, ϕ) has a structure function ϕ that is monotone and nontrivial.

The ***dual*** of the system (N, ϕ) is the system (N, ϕ^D), defined by $\phi^D(S) = 1 - \phi(N - S)$.

The ***reliability*** $R_{N,\phi}$ of the system (N, ϕ) is the probability that the system functions at a random instant of time: $R_{N,\phi} = Pr(\phi(S) = 1)$.

The ***unreliability*** $U_{N,\phi}$ of the system is given by $U_{N,\phi} = Pr(\phi(S) = 0) = 1 - R_{N,\phi}$.

Facts:

1. System reliability depends not only on the reliability of its individual components, but also on the manner in which they are interconnected.

2. If the state of any component is statistically independent of the state of any other component, then the probability that $S \subseteq N$ is precisely the set of operating components is given by $\text{prob}(S) = \prod\limits_{i \in S} p_i \prod\limits_{j \notin S} q_j$.

3. The dual of the dual of a system (N, ϕ) is the original system (N, ϕ).

Examples:

1. Consider a system built from the set of components $N = \{1, 2, 3, 4\}$. Associate with each component a known weight: $w_1 = 5$, $w_2 = 7$, $w_3 = 4$, $w_4 = 8$. If $S \subseteq N$ is the set of operating components, then the system is considered to operate if $\sum_{i \in S} w_i > 12$. Thus $\phi(S) = 1$ for precisely the following sets S:

$$\{1,4\},\ \{2,4\},\ \{1,2,3\},\ \{1,2,4\},\ \{1,3,4\},\ \{2,3,4\},\ \{1,2,3,4\}.$$

In all other cases $\phi(S) = 0$. This structure function is nontrivial and monotone, so that (N, ϕ) is a coherent system. The reliability of the system is then

$$R_{N,\phi} = p_1q_2q_3p_4 + q_1p_2q_3p_4 + p_1p_2p_3q_4 + p_1p_2q_3p_4 + p_1q_2p_3p_4 + q_1p_2p_3p_4 + p_1p_2p_3p_4.$$

The dual system (N, ϕ^D) has the structure function ϕ^D, where $\phi^D(T) = 0$ for precisely the following component sets T:

$$\emptyset, \{1\},\ \{2\},\ \{3\},\ \{4\},\ \{1,3\},\ \{2,3\}.$$

In all other cases $\phi^D(T) = 1$. For example, $\phi^D(\{1,3\}) = 1 - \phi(\{2,4\}) = 1 - 1 = 0$.

2. For critical financial transactions, calculations are carried out simultaneously by three separate microprocessors. The three results are compared and the result is accepted if any two of the processors agree (or all three agree). Here the system has components $\{1, 2, 3\}$ corresponding to the three microprocessors. A component fails if it gives the wrong answer, and the system fails if this "majority rule" produces an incorrect (or inconclusive) answer. Thus, $\phi(S) = 1$ if and only if S is $\{1, 2\}$, $\{1, 3\}$, $\{2, 3\}$, or $\{1, 2, 3\}$.

This structure function is nontrivial and monotone, so the system is coherent. If the microprocessors are identical and each operates independently with probability p, then $Pr(\text{exactly two components work}) = 3p^2(1 - p)$, $Pr(\text{all components work}) = p^3$, and

$$R_{N,\phi} = 3p^2(1 - p) + p^3 = 3p^2 - 2p^3.$$

For example, if $p = 0.95$ then $R_{N,\phi} = 0.99275$. In this case, even though any single microprocessor has a 5% failure rate, the system as a whole has only a 0.7% failure rate.

3. *Telephone network*: The components of this system are individual communication links (or trunk lines) joining nearby locations. Any telephone call placed between two distant locations in this system needs to be routed along available communication links.

However, as a result of hardware or software malfunctions, or as a result of overloaded circuits, certain links may be unavailable at a given instant of time. Thus, a telephone network can be modeled as a system whose components are subject to failure at random times. The reliability of the entire system is the probability that the system functions at a random instant of time; that is, that at any random point in time users can successfully complete their calls.

7.6.2 COHERENT SYSTEMS

It is assumed throughout this subsection that the system (N, ϕ) is coherent.

Definitions:

A ***minpath*** P is a minimal set of components such that $\phi(P) = 1$: i.e., $\phi(P) = 1$ and $\phi(S) = 0$ for all proper subsets $S \subset P$. The collection of all minpaths for (N, ϕ) is denoted $\mathcal{P}$.

A ***mincut*** C is a minimal set of components such that $\phi(N - C) = 0$: i.e., $\phi(N - C) = 0$ and $\phi(N - S) = 1$ for all proper subsets $S \subset C$. The collection of all mincuts for (N, ϕ) is denoted $\mathcal{C}$.

Let $G = (V, E)$ be an undirected graph with vertex set V and edge set E (§8.1.1).

- A ***simple path*** in G is a path that contains no repeated vertices.
- An ***s-t cutset*** of G is a minimal set of edges, the removal of which leaves no s-t path in G.
- A ***cutset*** of G is a minimal set of edges, the removal of which disconnects G.

If $K \subseteq V$, a ***K-tree*** is a minimal set F of edges in G such that every two vertices of K are joined by a path in F.

If $K \subseteq V$, a ***K-cutset*** is a minimal set of edges in G, the removal of which disconnects some pair of vertices in K.

Facts:

1. The dual of a coherent system is itself coherent.

2. The structure function of a coherent system (N, ϕ) can be completely described using its minpaths $\mathcal{P}$ or using its mincuts $\mathcal{C}$. Specifically

- $\phi(S) = 1$ if and only if S contains some minpath P;
- $\phi(S) = 0$ if and only if $N - S$ contains some mincut C.

3. The minpaths of (N, ϕ) are the mincuts of the dual (N, ϕ^D), and conversely.

4. The mincuts of (N, ϕ) are the minpaths of the dual (N, ϕ^D), and conversely.

5. Every minpath of (N, ϕ) and every mincut of (N, ϕ) have nonempty intersection.

6. If P is a minimal set of components that has nonempty intersection with every mincut of (N, ϕ), then P is a minpath of (N, ϕ).

7. If C is a minimal set of components that has nonempty intersection with every minpath of (N, ϕ), then C is a mincut of (N, ϕ).

8. A K-tree has the topology of a tree (§9.1.1) whose leaf vertices are in K.

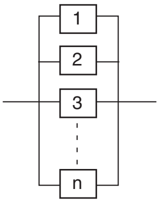
Examples:

1. *Series system*: This system (N, ϕ) operates only when all components of N operate. See the following figure. General characteristics are listed in Table 1.

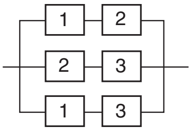
Table 1: Characteristics of series and parallel systems.

	series	*parallel*
structure function	$\phi(S) = 0$, if $S \subset N$ $\phi(N) = 1$	$\phi(S) = 1$, if $S \neq \emptyset$ $\phi(\emptyset) = 0$
minpaths	$P_1 = N$	$P_1 = \{1\}, P_2 = \{2\}, \ldots, P_n = \{n\}$
mincuts	$C_1 = \{1\}, C_2 = \{2\}, \ldots, C_n = \{n\}$	$C_1 = N$
reliability	$p_1 p_2 \ldots p_n$	$1 - (1 - p_1)(1 - p_2) \ldots (1 - p_n)$
unreliability	$1 - p_1 p_2 \ldots p_n$	$(1 - p_1)(1 - p_2) \ldots (1 - p_n)$
dual	parallel, n components	series, n components

2. *Parallel system*: This system (N, ϕ) fails only when all components of N fail. See the following figure. General characteristics are listed in Table 1.



3. *k-out-of-n success system*: This system (N, ϕ) operates only when at least k out of the n components operate. The following figure illustrates a 2-out-of-3 success system. General characteristics are listed in Table 2. The special case $k = 1$ gives a parallel system; $k = n$ gives a series system.



4. *k-out-of-n failure system*: This system (N, ϕ) fails only when at least k out of the n components fail. This is the same as an $(n - k + 1)$-out-of-n success system. General characteristics are listed in Table 2. The special case $k = 1$ gives a series system; $k = n$ gives a parallel system.

5. *Two-terminal network*: Two vertices s, t of an undirected graph $G = (V, E)$ are specified and a message is to be sent from vertex s to vertex t. Assume that only the edges are failure-prone, so $N = E$. The system operates when there exists some path of operating edges joining s to t in the graph.

- *structure function*: $\phi(S) = 1$ if there exists a path from s to t in the subgraph defined by edges S; $\phi(S) = 0$ otherwise;

- *minpaths*: all simple s-t paths of G;
- *mincuts*: all s-t cutsets of G;
- *reliability*: $R_{N,\phi}$ = the probability that a message sent from s will arrive at t = $\sum\{\text{prob}(S) \mid S \text{ contains some simple } s\text{-}t \text{ path}\}$;
- *unreliability*: $U_{N,\phi} = \sum\{\text{prob}(N-S) \mid S \text{ contains some } s\text{-}t \text{ cutset}\}$.

Table 2: Characteristics of k-out-of-n systems.

	k-out-of-n success	*k-out-of-n failure*
structure function	$\phi(S)=1$ if $\lvert S\rvert \geq k$ $\phi(S)=0$ if $\lvert S\rvert < k$	$\phi(S)=0$ if $\lvert S\rvert \leq n-k$ $\phi(S)=1$ if $\lvert S\rvert > n-k$
minpaths	$S \subseteq N$ with $\lvert S\rvert = k$	$S \subseteq N$ with $\lvert S\rvert = n-k+1$
mincuts	$S \subseteq N$ with $\lvert S\rvert = n-k+1$	$S \subseteq N$ with $\lvert S\rvert = k$
reliability	$\sum\{\text{prob}(S) \mid \lvert S\rvert \geq k\}$	$\sum\{\text{prob}(N-S) \mid \lvert S\rvert < k\}$
unreliability	$\sum\{\text{prob}(S) \mid \lvert S\rvert < k\}$	$\sum\{\text{prob}(N-S) \mid \lvert S\rvert \geq k\}$
dual	k-out-of-n failure	k-out-of-n success

6. *All-terminal network*: A message is to be disseminated among all vertices V in the undirected graph $G=(V,E)$. The system operates when the operating edges in the graph allow all vertices to mutually communicate.

- *structure function*: $\phi(S)=1$ if the subgraph defined by vertices V and edges S is connected; $\phi(S)=0$ otherwise;
- *minpaths*: all spanning trees (§9.2) of G;
- *mincuts*: all cutsets of G;
- *reliability*: $R_{N,\phi}$ = probability that G is connected = $\sum\{\text{prob}(S) \mid S$ contains some spanning tree of $G\}$;
- *unreliability*: $U_{N,\phi} = \sum\{\text{prob}(N-S) \mid S \text{ contains some cutset of } G\}$.

7. *All-terminal network, equal operating probabilities*: Suppose the undirected graph $G=(V,E)$ has $n=|V|$ vertices and $m=|E|$ edges, and suppose each edge has the same operating probability p. Let $q=1-p$ be the common edge failure probability. Then the all-terminal reliability $R(G,p)$ can be calculated as

$$R(G,p) = \sum_{i=0}^{m} F_i p^{m-i} q^i,$$

where F_i counts the number of operating system states in which exactly $m-i$ edges are functioning.

- $0 \leq F_i \leq \binom{m}{i}$ for $i=0,1,\ldots,m$;
- $F_i = 0$ for $i > m-n+1$;
- $F_i = \binom{m}{i}$ for $i < c$, where c is the minimum cardinality of a cutset of G;
- *Sperner's bound*: $iF_i \leq (m-i+1)F_{i-1}$.

8. *K-terminal network*: A message is to be disseminated among a fixed subset K of vertices in the undirected graph $G=(V,E)$. The system operates when the operating edges of the graph allow all vertices in K to mutually communicate.

- *structure function*: $\phi(S)=1$ if the subgraph defined by vertices K and edges S is connected; $\phi(S)=0$ otherwise;

- *minpaths*: all K-trees of G;
- *mincuts*: all K-cutsets of G;
- *reliability*: $R_{N,\phi}$ = probability that K is connected $= \sum\{\mathrm{prob}(S) \mid S$ contains some K-tree of $G\}$;
- *unreliability*: $U_{N,\phi} = \sum\{\mathrm{prob}(N-S) \mid S$ contains some K-cutset of $G\}$;
- *special cases*: $K = \{s,t\}$ gives the two-terminal network problem; $K = V$ gives the all-terminal network problem.

9. Examples 5–8 are defined in terms of undirected networks. The two-terminal, all-terminal, and K-terminal reliability problems described in these examples can also be defined for directed networks.

10. Consider the coherent system (N,ϕ) on components $N = \{1,2,3,4,5\}$ with minpaths $P_1 = \{1,2\}, P_2 = \{1,5\}, P_3 = \{3,5\}, P_4 = \{2,3,4\}$. To illustrate Fact 2, notice that $\phi(\{3,5\}) = 1$ and $\phi(\{2,3,5\}) = 1$ since P_3 is a minpath. Also, $\phi(\{2,5\}) = 0$ since $\{2,5\}$ contains no minpath. By Fact 7, $C_1 = \{1,3\}$ is a mincut for this system since C_1 has nonempty intersection with each of $P_1, P_2, \ldots, P_4$ and since neither $\{1\}$ nor $\{3\}$ has this property. Likewise, $C_2 = \{2,5\}$ and $C_3 = \{1,4,5\}$ are mincuts for this system. Fact 4 shows that the dual (N,ϕ^D) has as its minpaths the mincuts of (N,ϕ): namely, $\{1,3\}$, $\{2,5\}$, and $\{1,4,5\}$. This means $\phi^D(\{1,3,4\}) = 1$ since $\{1,3,4\}$ contains the minpath $\{1,3\}$. Alternatively, from the definition $\phi^D(\{1,3,4\}) = 1 - \phi(\{2,5\}) = 1 - 0 = 1$.

7.6.3 CALCULATING SYSTEM RELIABILITY

Four general approaches can be used to calculate the reliability $R_{N,\phi}$ of a coherent system (N,ϕ). These are state-space enumeration, inclusion-exclusion, disjoint products, and factoring.

Notation:

Let $\mathcal{P} = \{P_1, P_2, \ldots, P_m\}$ be the minpaths and let $\mathcal{C} = \{C_1, C_2, \ldots, C_r\}$ be the mincuts of the coherent system (N,ϕ).

- E_i is the event that all components of minpath P_i operate (with no stipulation as to the states of the other components);
- F_i is the event that all components of C_i fail (with no stipulation as to the states of the other components);
- E_iE_j denotes the event that both E_i and E_j occur;
- (N,ϕ_{+i}) is the system derived from (N,ϕ) in which component i always works;
- (N,ϕ_{-i}) is the system derived from (N,ϕ) in which component i always fails.

Facts:

1. Calculation of the reliability $R_{N,\phi}$ is in general quite difficult; specifically, it is a #P-complete problem (see §17.5.3).

2. $R_{N,\phi} = \sum\{\mathrm{prob}(S) \mid \phi(S) = 1\}$.

3. $R_{N,\phi} = \sum\{\mathrm{prob}(S) \mid S$ contains some $P \in \mathcal{P}\}$.

4. $R_{N,\phi} = 1 - U_{N,\phi} = 1 - \sum\{\mathrm{prob}(N-S) \mid S$ contains some $C \in \mathcal{C}\}$.

5. *State-space enumeration*: System reliability can be found by enumerating all operating (or all failed) states of the system, using Facts 2–4.

6. $R_{N,\phi} = Pr(E_1 \cup E_2 \cup \cdots \cup E_m)$.

7. $U_{N,\phi} = Pr(F_1 \cup F_2 \cup \cdots \cup F_r)$.

8. Applying the inclusion-exclusion principle (§2.4) to Fact 6 produces

$$R_{N,\phi} = \textstyle\sum_i Pr(E_i) - \sum_{i<j} Pr(E_iE_j) + \cdots + (-1)^{m+1}\, Pr(E_1E_2 \ldots E_m).$$

9. Applying the inclusion-exclusion principle (§2.4) to Fact 7 produces

$$U_{N,\phi} = \textstyle\sum_i Pr(F_i) - \sum_{i<j} Pr(F_iF_j) + \cdots + (-1)^{r+1}\, Pr(F_1F_2 \ldots F_r).$$

10. *Inclusion-exclusion*: This approach calculates system reliability using Facts 8–9.

11. $R_{N,\phi} = Pr(E_1) + Pr(\overline{E}_1E_2) + \cdots + Pr(\overline{E}_1\overline{E}_2 \ldots \overline{E}_{m-1}E_m)$.

12. $U_{N,\phi} = Pr(F_1) + Pr(\overline{F}_1F_2) + \cdots + Pr(\overline{F}_1\overline{F}_2 \ldots \overline{F}_{r-1}F_r)$.

13. *Disjoint products*: This approach calculates system reliability using the law of total probability (§7.2.1). (See Facts 11–12.)

14. $R_{N,\phi} = p_iR_{N,\phi_{+i}} + (1-p_i)R_{N,\phi_{-i}}$.

15. *Factoring*: Rather than requiring an enumeration of the minpaths or mincuts of the system, this method (based on Fact 14) concentrates on the state of an individual component i: it is either operating (with probability p_i) or failed (with probability $q_i = 1 - p_i$).

16. The factoring method is applied most productively when the system (N, ϕ) has additional structure. For example, this approach can be used to determine the reliability of k-out-of-n systems and two-terminal networks. (See §7.6.4.)

Examples:

1. *State-space enumeration*: Consider the coherent system (N, ϕ) with $N = \{1, 2, 3, 4\}$ and minpaths $P_1 = \{2, 3\}$, $P_2 = \{1, 2, 4\}$, $P_3 = \{1, 3, 4\}$. By Fact 2 of §7.6.2, the operating states of the system are $\{2, 3\}, \{1, 2, 3\}, \{1, 2, 4\}, \{1, 3, 4\}, \{2, 3, 4\}$, and $\{1, 2, 3, 4\}$. By Fact 3, $R_{N,\phi} = q_1p_2p_3q_4 + p_1p_2p_3q_4 + p_1p_2q_3p_4 + p_1q_2p_3p_4 + q_1p_2p_3p_4 + p_1p_2p_3p_4$.

2. *Inclusion-exclusion*: Consider the coherent system on $N = \{1, 2, 3, 4\}$ with minpaths $P_1 = \{1, 2\}$, $P_2 = \{2, 4\}$, $P_3 = \{1, 3, 4\}$. Event E_1 has probability p_1p_2, event E_1E_2 has probability $p_1p_2p_4$, etc. Fact 8 gives

$$\begin{aligned} R_{N,\phi} &= p_1p_2 + p_2p_4 + p_1p_3p_4 - p_1p_2p_4 - p_1p_2p_3p_4 - p_1p_2p_3p_4 + p_1p_2p_3p_4 \\ &= p_1p_2 + p_2p_4 + p_1p_3p_4 - p_1p_2p_4 - p_1p_2p_3p_4. \end{aligned}$$

3. *Disjoint products*: Fact 11 is applied to the coherent system on $N = \{1, 2, 3, 4, 5, 6\}$ with minpaths $P_1 = \{1, 5\}$, $P_2 = \{1, 3, 6\}$, $P_3 = \{2, 4, 5\}$, $P_4 = \{2, 6\}$. For simplicity of notation, let the event $\{e \text{ operates}\}$ be denoted by e, and let the event $\{e \text{ fails}\}$ be denoted by $\bar{e}$. Identities of set theory (see §1.2.2) can then be used to obtain

$$\begin{aligned} Pr(E_1) &= p_1p_5; \\[1ex] Pr(\overline{E}_1E_2) &= Pr((\bar{1} \cup \bar{5})136) = Pr(\bar{5}136) = p_1p_3q_5p_6; \\[1ex] Pr(\overline{E}_1\overline{E}_2E_3) &= Pr((\bar{1} \cup \bar{5})(\bar{1} \cup \bar{3} \cup \bar{6})245) = Pr(\bar{1}(\bar{1} \cup \bar{3} \cup \bar{6})245) \\ &= Pr(\bar{1}245) = q_1p_2p_4p_5; \\[1ex] Pr(\overline{E}_1\overline{E}_2\overline{E}_3E_4) &= Pr((\bar{1} \cup \bar{5})(\bar{1} \cup \bar{3} \cup \bar{6})(\bar{2} \cup \bar{4} \cup \bar{5})26) \\ &= Pr((\bar{1} \cup \bar{5})(\bar{1} \cup \bar{3})(\bar{4} \cup \bar{5})26) \\ &= Pr((\bar{1} \cup \bar{3}\bar{5})(\bar{4} \cup \bar{5})26) \\ &= Pr((\bar{1}\bar{4} \cup \bar{1}\bar{5} \cup \bar{3}\bar{5})26). \end{aligned}$$

Since the events $\bar{1}\bar{4}$, $\bar{1}\bar{5}$, and $\bar{3}\bar{5}$ above are not disjoint, Fact 11 can be reapplied to this new union of events, yielding

$$\begin{aligned} Pr(\overline{E}_1\overline{E}_2\overline{E}_3E_4) &= Pr((\bar{1}\bar{4} \cup 4\bar{1}\bar{5} \cup 1\bar{3}\bar{5})26) \\ &= Pr(\bar{1}\bar{4}26 \cup 4\bar{1}\bar{5}26 \cup 1\bar{3}\bar{5}26) \\ &= q_1p_2q_4p_6 + q_1p_2p_4q_5p_6 + p_1p_2q_3q_5p_6. \end{aligned}$$

The final expression for system reliability is then

$$R_{N,\phi} = p_1p_5 + p_1p_3q_5p_6 + q_1p_2p_4p_5 + q_1p_2q_4p_6 + q_1p_2p_4q_5p_6 + p_1p_2q_3q_5p_6.$$

7.6.4 SPECIALIZED ALGORITHMS FOR CALCULATING RELIABILITY

The general methods for calculating system reliability discussed in §7.6.3 can often be streamlined when the system has a special structure. This section describes algorithms for calculating the reliability of series-parallel, k-out-of-n, and certain network systems.

Definitions:

The ***two-terminal reliability*** of a network G is the probability $R_{st}(G)$ that vertices s and t are connected in G.

The ***all-terminal reliability*** of a network G is the probability $R_V(G)$ that G is connected.

If G is a two-terminal network with specified vertices s and t, then an ***irrelevant*** edge is one not appearing in any simple s-t path of G.

Let $G_S = (V_S, E_S)$ be the subgraph of a directed graph $G = (V, E)$ induced by edges $S \subseteq E$. If G_S is acyclic and has no irrelevant edges, the ***domination*** of G_S is $d_S = (-1)^{|E_S|-|V_S|+1}$; in all other cases, define $d_S = 0$.

Define $f_k(n)$ to be the reliability of a k-out-of-n success system having the components $N = \{1, 2, \ldots, n\}$ and corresponding reliabilities $p_1, p_2, \ldots, p_n$.

Facts:

1. A parallel system has reliability $f_1(n) = 1 - (1 - p_1)(1 - p_2) \ldots (1 - p_n)$.

2. A series system has reliability $f_n(n) = p_1p_2 \ldots p_n$.

3. *Series-parallel system*: If a system is constructed from series and parallel subsystems (with no component appearing in more than one subsystem), then the reliability of the overall system is calculated by successively applying Facts 1 and 2.

4. Applying the factoring approach of §7.6.3 to a k-out-of-n success system gives $f_k(n) = p_nf_{k-1}(n-1) + (1 - p_n)f_k(n-1)$.

5. *k-out-of-n system*: Repeated application of Facts 1, 2, and 4 produces the reliability of any k-out-of-n success system. Since a k-out-of-n failure system is the same as an $(n - k + 1)$-out-of-n success system, the reliability of any k-out-of-n failure system is found in a similar way.

6. For a two-terminal undirected network G, the system (N, ϕ_{-e}) corresponds to the two-terminal network $G - e$ with edge e deleted.

7. For a two-terminal undirected network G, the system (N, ϕ_{+e}) corresponds to the two-terminal network G/e in which edge e is contracted.

8. *Two-terminal undirected network*: Algorithm 1 is a recursive procedure that calculates $R_{st}(G)$. Based on the factoring approach of §7.6.3, it splits the initial reliability calculation for G into calculations for the smaller networks $G - e$ and G/e.

Algorithm 1: **Two-terminal reliability for undirected networks.**

```
procedure $R_{st}(G)$
perform series and parallel reductions on $G$, producing network $H$
if $H$ consists of the single edge $(s,t)$ then return the reliability of $(s,t)$
else
   select an edge $e$ from $H$
   let $p_e$ be the reliability of $e$ in $H$
   return  $p_e\, R_{st}(H/e) + (1 - p_e)\, R_{st}(H - e)$
```

9. For the sake of efficiency, Algorithm 1 carries out any applicable series and parallel reductions before selecting an edge on which to factor.

10. To avoid redundant calculations in Algorithm 1, edge e should be chosen from H so that H/e and $H - e$ do not contain irrelevant edges.

11. If G is a two-terminal directed network, then $R_{st}(G) = \sum_S d_S \prod_{i \in S} p_i$.

12. The expression in Fact 11 is obtained by using the inclusion-exclusion expansion (§7.6.3, Fact 8) applied to the simple s-t paths of G. Remarkably, a number of terms in this expansion cancel one another and the remaining coefficients are either $+1$ or -1.

13. In an undirected network $G = (V, E)$, the minpaths for the all-terminal problem are the spanning trees of G.

14. *All-terminal reliability*: Algorithm 2 calculates $R_V(G)$ using the disjoint-products expansion (§7.6.3, Fact 11), applied to the spanning trees in lexicographic (dictionary) order. Here each term of the expansion reduces to a single product involving p_i and $q_i = 1 - p_i$.

Algorithm 2: **All-terminal reliability for undirected networks.**

```
input: undirected network $G$
output: $R_V(G)$
let $T_1, T_2, \ldots, T_m$ be the spanning trees of $G$, listed in lexicographic order
for $k := 1$ to $m$
   $S_k := T_k$
   $F_k := \emptyset$
   for $j := 1$ to $k - 1$
      $F_k := F_k \cup \min\{r \mid r \in T_j - T_k\}$
   $g_k := \prod_{i \in S_k} p_i \; \prod_{i \in F_k} q_i$
$R_V(G) := \sum_{k=1}^{m} g_k$
```

Examples:

1. A system on four components is built up from series and parallel subsystems. Subsystem A has components 1 and 2 in series and subsystem B consists of component 3. Subsystem C has these two subsystems in parallel and its reliability is $1-(1-p_1p_2)(1-p_3) =$

$p_1p_2 + p_3 - p_1p_2p_3$. The entire system is constructed from subsystem D (component 4 alone) in series with subsystem C, so it has reliability $p_4(p_1p_2 + p_3 - p_1p_2p_3) = p_1p_2p_4 + p_3p_4 - p_1p_2p_3p_4$.

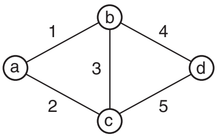
2. To calculate the reliability of a 2-out-of-3 success system with components $1, 2, 3$, Facts 1 and 2 are first used to obtain

$$f_1(2) = 1 - (1 - p_1)(1 - p_2) = p_1 + p_2 - p_1p_2, \quad f_2(2) = p_1p_2.$$

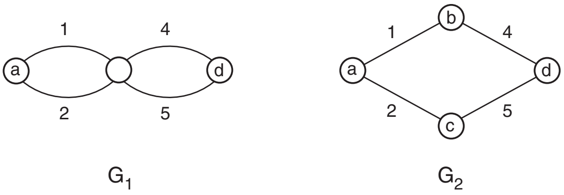
Fact 4 then gives the system reliability

$$R_{N,\phi} = f_2(3) = p_3f_1(2) + (1 - p_3)f_2(2) = p_1p_2 + p_1p_3 + p_2p_3 - 2p_1p_2p_3.$$

3. The two-terminal *bridge* network G is shown in the following figure, with $s = a$ and $t = d$.



No series or parallel reductions can be performed on G, so factoring with respect to edge $e = 3$ produces the networks $G_1 = G/e$ and $G_2 = G - e$ shown in the next figure.



Since both G_1 and G_2 are series-parallel networks,

$$\begin{aligned} R_{st}(G_1) &= [1 - (1 - p_1)(1 - p_2)][1 - (1 - p_4)(1 - p_5)] \\ &= (p_1 + p_2 - p_1p_2)(p_4 + p_5 - p_4p_5), \end{aligned}$$

$$R_{st}(G_2) = [1 - (1 - p_1p_4)(1 - p_2p_5)] = p_1p_4 + p_2p_5 - p_1p_2p_4p_5.$$

Algorithm 1 then produces

$$\begin{aligned} R_{st}(G) &= p_3(p_1 + p_2 - p_1p_2)(p_4 + p_5 - p_4p_5) + (1 - p_3)(p_1p_4 + p_2p_5 - p_1p_2p_4p_5) \\ &= p_1p_4 + p_2p_5 + p_1p_3p_5 + p_2p_3p_4 - p_1p_3p_4p_5 - p_2p_3p_4p_5 - p_1p_2p_3p_4 \\ &\quad - p_1p_2p_3p_5 - p_1p_2p_4p_5 + 2p_1p_2p_3p_4p_5. \end{aligned}$$

4. Consider a directed version of the two-terminal network in the figure of Example 3, in which there are oppositely directed edges $3 = (b, c)$ and $6 = (c, b)$. Edges 1 and 2 are directed out of $s = a$, while edges 4 and 5 are directed into $t = d$. The cyclic subgraph defined by edges $S = \{1, 2, 3, 4, 5, 6\}$ has $d_S = 0$. Also the subgraph defined by $S = \{1, 2, 3, 4\}$ has the irrelevant edges 2 and 3, so that $d_S = 0$. On the other hand, $S = \{1, 2, 3, 5\}$ defines an acyclic network without irrelevant edges, giving $d_S = (-1)^{4-4+1} = -1$ and the term $-p_1p_2p_3p_5$. Similarly, $S = \{1, 4\}$ produces $d_S = (-1)^{2-3+1} = +1$ and the term $+p_1p_4$.

After generating all acyclic networks without irrelevant edges, Fact 11 is applied to obtain

$$\begin{aligned} R_{st}(G) &= p_1p_4 + p_2p_5 + p_1p_3p_5 + p_2p_4p_6 - p_1p_2p_4p_5 - p_1p_3p_4p_5 \\ &\quad - p_1p_2p_4p_6 - p_1p_2p_3p_5 - p_2p_4p_5p_6 + p_1p_2p_3p_4p_5 + p_1p_2p_4p_5p_6. \end{aligned}$$

5. The bridge network G in Example 3 has eight spanning trees, given in lexicographic order by $T_1 = \{1,2,4\}$, $T_2 = \{1,2,5\}$, $T_3 = \{1,3,4\}$, $T_4 = \{1,3,5\}$, $T_5 = \{1,4,5\}$, $T_6 = \{2,3,4\}$, $T_7 = \{2,3,5\}$, $T_8 = \{2,4,5\}$. Applying Algorithm 2 gives

$$\begin{array}{lll} S_1 = \{1,2,4\}, & F_1 = \emptyset, & g_1 = p_1p_2p_4 \\ S_2 = \{1,2,5\}, & F_2 = \{4\}, & g_2 = p_1p_2q_4p_5 \\ S_3 = \{1,3,4\}, & F_3 = \{2\}, & g_3 = p_1q_2p_3p_4 \\ S_4 = \{1,3,5\}, & F_4 = \{2,4\}, & g_4 = p_1q_2p_3q_4p_5 \\ \vdots & \vdots & \vdots \\ S_8 = \{2,4,5\}, & F_8 = \{1,3\}, & g_8 = q_1p_2q_3p_4p_5 \end{array}$$

Summing these eight terms then yields

$$R_V(G) = p_1p_2p_4 + p_1p_2q_4p_5 + p_1q_2p_3p_4 + p_1q_2p_3q_4p_5 + \cdots + q_1p_2q_3p_4p_5.$$

6. The all-terminal reliability of the bridge network G given in Example 3 can also be calculated by determining the coefficients F_i discussed in Example 7 of §7.6.2. Here we assume that all edges operate with probability p and fail with probability $q = 1 - p$. Notice that $c = 2$ is the minimum cardinality of a cutset in G. Therefore, $F_0 = \binom{5}{0} = 1$ and $F_1 = \binom{5}{1} = 5$. At the other extreme, $F_i = 0$ for $i > m - n + 1 = 2$. The only remaining coefficient is F_2, obtained by noting that G remains connected whenever any three of the five edges operate, except for $\{1,2,3\}$ and $\{3,4,5\}$, so that $F_2 = \binom{5}{2} - 2 = 8$. This gives $R(G,p) = p^5 + 5p^4q + 8p^3q^2$.

7.7 DISCRETE-TIME MARKOV CHAINS

Many physical systems evolve randomly in time, e.g., the population of a country, the value of a company's stock, the number of customers waiting at a checkout counter, and the functional state of a machine subject to failures and repairs. A discrete-time Markov chain can be used to model such situations when the set of possible states of the system is finite (or countable) and the system changes state at discrete time points. Such Markov chain models find applications in diverse fields, such as biology, computer science, inventory, production, queueing systems, and demography. In addition, many recursive algorithms can be viewed as a manifestation of an underlying discrete-time Markov chain.

7.7.1 MARKOV CHAINS

Definitions:

A sequence of random variables $\{X_n \mid n \geq 0\}$ is a (***discrete-time***) ***Markov chain*** (***DTMC***) on a (countable) state space S if $X_n \in S$ for all $n \geq 0$ and X_{n+1} depends (probabilistically) on the previous states of the system only via X_n:

$$Pr(X_{n+1} = j \mid X_n = i, X_{n-1} = i_{n-1}, ..., X_0 = i_0) = Pr(X_{n+1} = j \mid X_n = i),$$

for all $i_0, i_1, ..., i_{n-1}, i, j \in S$.

A Markov chain $\{X_n \mid n \geq 0\}$ is ***time-homogeneous*** if

$$Pr(X_{n+1} = j \mid X_n = i) = p_{ij}, \text{ for all } n \geq 0.$$

Note: Only time-homogeneous discrete-time Markov chains will be considered in this and later sections.

The matrix $P = (p_{ij})$ is the (***one-step***) ***transition probability matrix*** of the discrete-time Markov chain.

The ***initial distribution*** for a DTMC is the vector $a = (a_i)$, where $a_i = Pr(X_0 = i)$ for $i \in S$.

The ***transition diagram*** of a DTMC is the directed graph (§8.3.1) $G = (V, E)$, where $V = S$ is the state space and $E = \{(i, j) \in S \times S \mid p_{ij} > 0\}$.

A ***stochastic*** matrix $M = (m_{ij})$ has $m_{ij} \geq 0$ for all i, j and $\sum_j m_{ij} = 1$ for all i.

Facts:

1. The first systematic study of Markov chains was carried out by Andrei Andreevich Markov (1856–1922); this work initiated the study of stochastic processes (sequences of random variables).

2. A DTMC on state space S is completely described by the initial distribution a and the transition probability matrix P.

3. The transition probability matrix P is a stochastic matrix.

Examples:

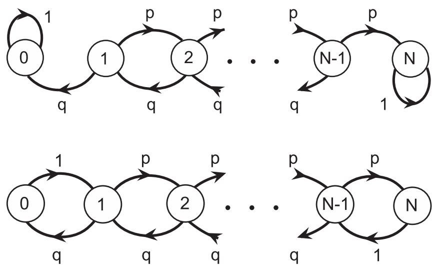
1. Consider a DTMC on the set $S = \{1, 2, 3, 4, 5, 6\}$ with the following transition probability matrix

$$P = \begin{pmatrix} 0.4 & 0.6 & 0 & 0 & 0 & 0 \\ 0.7 & 0.3 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0.1 & 0.1 & 0.1 & 0.1 & 0.1 & 0.5 \end{pmatrix}$$

To completely describe this DTMC, it is also necessary to specify the initial distribution. For example, $a = (0, 0, 0, 0, 0, 1)$ means that the system starts off in state 6.

2. *Simple random walk with absorbing states*: This is a DTMC on $S = \{0, 1, 2, ..., N\}$ with transition probabilities $p_{i,i+1} = p$, $p_{i,i-1} = 1 - p = q$, $1 \leq i \leq N - 1$, where $0 \leq p \leq 1$ is a given number. Also, $p_{0,0} = p_{N,N} = 1$, meaning that states 0 and N are absorbing: once the DTMC visits these states it cannot leave them. This Markov model is also (more colorfully) known as the *gambler's ruin problem* (§7.5.1, Example 2). The transition diagram of this DTMC is given in the following figure.

3. *Simple random walk with reflecting states*: This is a variant of Example 2, in which the boundary states 0 and N are reflecting: namely, $p_{0,1} = p_{N,N-1} = 1$. The transition diagram of this DTMC is shown next.



4. *Weather*: A simplified model of the daily weather results in a DTMC. Suppose that each day is either sunny (0) or rainy (1) and that tomorrow's weather depends only on today's weather. Specifically, suppose that a rainy day follows a sunny day with probability 0.3 and a sunny day follows a rainy day with probability 0.4. This is a DTMC with state space $S = \{0, 1\}$ and transition probability matrix

$$P = \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix}.$$

5. *Urns*: Urn B contains nine black and one white ball, while Urn R contains six red and four white balls. Balls are successively drawn with replacement from an urn. If the ball drawn is colored, the drawing continues from the same urn. If the ball drawn is white, the drawing continues from the other urn. Define the state of the system to be the urn being sampled, so $S = \{\text{B, R}\}$. This is a DTMC with transition probabilities $p_{BB} = 0.9$, $p_{BR} = 0.1$, $p_{RR} = 0.6$, $p_{RB} = 0.4$.

6. *Ehrenfest diffusion model*: Suppose that there are M molecules in a vessel, separated into two chambers by a membrane, across which molecules can pass. A state of the system at any instant is given by (k_1, k_2), where there are k_1 molecules in the first chamber and $k_2 = M - k_1$ in the second chamber. Transitions from the current state (k_1, k_2) occur by the movement of a single molecule from the first chamber to the second, resulting in state $(k_1 - 1, k_2 + 1)$, or from the second chamber to the first, resulting in state $(k_1 + 1, k_2 - 1)$.

In the Ehrenfest model of this process, the probability of transition from (k_1, k_2) to $(k_1 - 1, k_2 + 1)$ is given by $\frac{k_1}{M}$, whereas the probability of transition to $(k_1 + 1, k_2 - 1)$ is $\frac{k_2}{M} = 1 - \frac{k_1}{M}$. This quantifies the idea that if more molecules are present in (say) chamber 1, then it is more likely for some molecule to transfer next from chamber 1 to chamber 2. This is a DTMC with state space $S = \{(0, M), (1, M-1), \ldots, (M, 0)\}$ and the transition probabilities specified.

7.7.2 TRANSIENT ANALYSIS

Transient analysis of a DTMC involves the computation of $Pr(X_n = j)$, the probability of the Markov chain being in state j after n steps.

Definitions:

For $i, j \in S$ the ***n*-step transition probability** $p_{ij}^{(n)}$ is the probability of being in state j after $n \geq 0$ steps, if the Markov chain starts in state i: $p_{ij}^{(n)} = Pr(X_n = j \mid X_0 = i)$.

The ***n*-step transition probability matrix** is given by $P^{(n)} = (p_{ij}^{(n)})$.

Facts:

1. $Pr(X_n = j) = \sum_{i \in S} Pr(X_0 = i)\, Pr(X_n = j \mid X_0 = i) = \sum_{i \in S} a_i p_{ij}^{(n)}$.

2. *Chapman-Kolmogorov equations*: $P^{(n+m)} = P^{(n)} P^{(m)} = P^{(m)} P^{(n)}$ for all $m, n \geq 0$.

3. If P^n denotes the nth power of P, then $P^{(n)} = P^n$, $n \geq 0$.

4. If a is the initial distribution of a DTMC, the (absolute) probabilities $Pr(X_n = j)$ are the entries of the vector aP^n.

Examples:

1. For Example 4 of §7.7.1, the two-step transition probability matrix is

$$P^{(2)} = P^2 = \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} \begin{pmatrix} 0.7 & 0.3 \\ 0.4 & 0.6 \end{pmatrix} = \begin{pmatrix} 0.61 & 0.39 \\ 0.52 & 0.48 \end{pmatrix}.$$

Note that $P^{(2)}$ is again a stochastic matrix. To illustrate, if Friday is sunny then the conditional probability that the following Sunday is sunny is given by $p_{00}^{(2)} = 0.61$.

2. A general two-state DTMC on $S = \{0, 1\}$ can be represented by the stochastic transition probability matrix

$$P = \begin{pmatrix} 1-p & p \\ q & 1-q \end{pmatrix}.$$

Direct calculation gives the two-step transition probability matrix

$$P^{(2)} = \begin{pmatrix} (1-p)^2 + pq & p(2-p-q) \\ q(2-p-q) & (1-q)^2 + pq \end{pmatrix},$$

which can be rewritten as

$$P^{(2)} = \frac{1}{p+q} \begin{pmatrix} q + p(1-p-q)^2 & p - p(1-p-q)^2 \\ q - q(1-p-q)^2 & p + q(1-p-q)^2 \end{pmatrix}.$$

In general,

$$P^{(n)} = \frac{1}{p+q} \begin{pmatrix} q + p(1-p-q)^n & p - p(1-p-q)^n \\ q - q(1-p-q)^n & p + q(1-p-q)^n \end{pmatrix}.$$

3. *Limiting probabilities*: Suppose in Example 2 that $0 < p < 1$ and $0 < q < 1$, so that $|1-p-q| < 1$. From the final expression obtained in Example 2, it is seen that $P^{(n)}$ tends to the limiting matrix

$$\frac{1}{p+q} \begin{pmatrix} q & p \\ q & p \end{pmatrix}.$$

Consequently, if $a = (a_1, a_2)$ is any initial distribution, then the limiting probabilities aP^n approach

$$\frac{1}{p+q} \begin{pmatrix} a_1 & a_2 \end{pmatrix} \begin{pmatrix} q & p \\ q & p \end{pmatrix} = \frac{1}{p+q} \begin{pmatrix} q & p \\ q & p \end{pmatrix}$$

since $a_1 + a_2 = 1$. For example, the limiting probability of being in state 0 is $\frac{q}{p+q}$, independent of the initial state of the DTMC. (See §7.7.4.)

7.7.3 CLASSIFICATION OF STATES

Definitions:

State $j \in S$ is ***accessible*** from state $i \in S$ (written $i \to j$) if it is possible to make a sequence of transitions leading from state i to state j: that is, $p_{ij}^{(n)} > 0$ for some $n \geq 0$.

States $i, j \in S$ ***communicate*** (written $i \leftrightarrow j$) if they are mutually accessible from one another: $i \to j$ and $j \to i$.

Set $C \subseteq S$ is a (maximal) ***communicating class*** if

- $i, j \in C \Rightarrow i \leftrightarrow j$;
- $i \in C$, $i \leftrightarrow j \Rightarrow j \in C$.

A communicating class C is ***closed*** if transitions from the states of C never lead to states outside C: $i \in C$, $j \notin C \Rightarrow j$ is not accessible from i.

A DTMC is ***irreducible*** if $i \leftrightarrow j$ for all $i, j \in S$; otherwise it is ***reducible***.

For $j \in S$ define

- $T_j = \min\{n > 0 \mid X_n = j\}$;
- $f_j = Pr(T_j < \infty \mid X_0 = j)$;
- $f_j(n) = Pr(T_j = n \mid X_0 = j)$;
- $m_j = E(T_j \mid X_0 = j)$.

State $j \in S$ is ***recurrent*** if return to that state is certain: $f_j = 1$; if $f_j < 1$ then state j is ***transient***. A recurrent state $j \in S$ is ***positive recurrent*** if $m_j < \infty$ and **null recurrent** if $m_j = \infty$.

A recurrent state j has ***period*** d if d is the largest integer satisfying $\sum_{n=0}^{\infty} f_j(nd) = 1$. If $d = 1$ then state j is ***aperiodic***.

Facts:

1. Generally, all classes that are not closed can be lumped into a single set T of transient states. Thus, the state space of a DTMC can be partitioned into closed classes $C_1, C_2, \ldots, C_K$ and the set T.

2. State j is accessible from state i if and only if there is a directed path from vertex i to vertex j in the transition diagram of the DTMC.

3. A set of states C is a communicating class if and only if the corresponding set of vertices forms a strongly connected component (§8.3.2) in the transition diagram.

4. Tarjan [Ta72] describes an algorithm to find the strongly connected components, which runs in time linear in the number of arcs in the transition diagram (i.e., the number of nonzero entries of P).

5. Transience, positive recurrence, and null recurrence are class properties:

- if i is transient and $i \leftrightarrow j$ then j is transient;
- if i is positive recurrent and $i \leftrightarrow j$ then j is positive recurrent;
- if i is null recurrent and $i \leftrightarrow j$ then j is null recurrent.

In other words, states in a communicating class are all simultaneously transient or null recurrent or positive recurrent.

6. By Fact 5, a communicating class or an irreducible DTMC can be termed positive recurrent, null recurrent, or transient if all of its states are positive recurrent, null recurrent, or transient.

7. A finite communicating class is positive recurrent if it is closed, and transient otherwise.

8. A finite state irreducible DTMC is positive recurrent.

9. Null recurrent states do not occur in a finite state DTMC.

10. Establishing recurrence or transience in an infinite state DTMC is a difficult task and has to be done on a case-by-case basis.

11. We have not defined period for a transient state since for such a state the concept is not needed. Some references do however define period for all states.

12. The period of state j is the greatest common divisor of all integers $n \geq 0$ such that $p_{jj}^{(n)} > 0$.

13. The period of state j is the greatest common divisor of all the lengths of the directed cycles in the transition diagram that contain state j.

14. Periodicity is a class property: if i has period d and $i \leftrightarrow j$, then j has period d.

15. The period of a state in a finite irreducible DTMC is at most equal to the number of states in the DTMC.

16. By Fact 14, a recurrent communicating class or a recurrent irreducible DTMC can be termed periodic if all states in it are periodic with $d > 1$, else it is termed aperiodic.

Examples:

1. For the DTMC in Example 1 of §7.7.1, it is seen that $1 \rightarrow 2$, $2 \rightarrow 1$, and $1 \leftrightarrow 2$. However, 3 is not accessible from 1. The communicating classes are $C_1 = \{1,2\}$, $C_2 = \{3,4\}$, $C_3 = \{5\}$, $C_4 = \{6\}$. This DTMC is reducible. Classes C_1, C_2, C_3 are closed, but C_4 is not. States $1,2,3,4,5$ are positive recurrent and state 6 is transient. Classes C_1, C_2, C_3 are positive recurrent.

2. Consider the random walk in Example 2 of §7.7.1 with $0 < p < 1$. There are three communicating classes: $C_1 = \{0\}$, $C_2 = \{1, 2, ..., N-1\}$, and $C_3 = \{N\}$. This DTMC is reducible. Here C_1 and C_3 are closed, while C_2 is not. States 0 and N are positive recurrent. The rest are transient.

3. For the DTMC in Example 1 of §7.7.1, states 3 and 4 have period 2; states 1, 2, and 5 are aperiodic. A period is not associated with state 6 since it is transient. Classes $\{1,2\}$ and $\{5\}$ are aperiodic, while the class $\{3,4\}$ is periodic with period 2.

4. For the DTMC in Example 2 of §7.7.1, states 0 and N are aperiodic. Period is not defined for the rest of the states as they are transient.

5. Example 3 of §7.7.1 is an irreducible chain. All states are positive recurrent and have period 2.

7.7.4 LIMITING BEHAVIOR

To establish possible equilibrium configurations of DTMCs, it is necessary to study the behavior of the n-step transition probabilities $Pr(X_n = j \mid X_0 = i)$ as $n \rightarrow \infty$.

Facts:

1. Let $\{X_n \mid n \geq 0\}$ be an irreducible DTMC with transition probability matrix P and finite state space S. Then there exists a unique solution $\pi = (\pi_j)$ to the equations

$$\pi = \pi P, \quad \sum_{j \in S} \pi_j = 1.$$

2. The long run fraction of the visits to state j is given by π_j, regardless of the initial state. Also, m_j, the expected time between two consecutive visits to state j, is $\frac{1}{\pi_j}$.

3. If the DTMC is aperiodic, then $\lim_{n\to\infty} Pr(X_n = j \mid X_0 = i) = \pi_j$ for all $i \in S$.

4. Let $\{X_n \mid n \geq 0\}$ be a finite state reducible DTMC with K closed communicating classes $C_1, C_2, \ldots, C_K$ and the set of transient states T. Then $\lim_{n\to\infty} Pr(X_n = j \mid X_0 = i) = \pi_{ij}$, where

(a) if $j \in T$, then $\pi_{ij} = 0$;

(b) if i and j belong to different closed classes, then $\pi_{ij} = 0$;

(c) if i and j belong to the same closed class C_r, then $\pi_{ij} = \pi_j$, where $\{\pi_j\}$ are the limiting probabilities calculated by using Fact 1 for the irreducible DTMC formed by the states in C_r;

(d) if $i \in T$ and $j \in C_r$, then $\pi_{ij} = \alpha_{ir}\pi_j$, where $\{\pi_j\}$ are as in (c) and α_{ir} is the probability that the DTMC eventually visits the class C_r starting from state i.

5. In Fact 4(c), if C_r is periodic then limiting probabilities do not exist and π_j is interpreted as the long run fraction of the time the DTMC spends in state j starting from state i.

6. The $\{\alpha_{ir}\}$ in Fact 4(d) are given by the unique solution to

$$\alpha_{ir} = \sum_{j \in C_r} p_{ij} + \sum_{j \in T} p_{ij}\alpha_{jr}.$$

Examples:

1. The DTMC in Example 3 of §7.7.1 is irreducible and periodic with $d = 2$. Using Fact 1, its limiting behavior is described by the equations

$$\begin{aligned}
\pi_0 &= q\pi_1 \\
\pi_1 &= \pi_0 + q\pi_2 \\
\pi_i &= p\pi_{i-1} + q\pi_{i+1} \quad \text{for } 2 \leq i \leq N-2 \\
\pi_{N-1} &= p\pi_{N-2} + \pi_N \\
\pi_N &= p\pi_{N-1}
\end{aligned}$$

and $\sum_{j=0}^{N} \pi_j = 1$. Solving these equations gives $\pi_j = \frac{\rho_j}{c}$, where

$$\begin{aligned}
\rho_0 &= 1 \\
\rho_j &= \frac{(\frac{p}{q})^j}{p} \quad \text{for } 1 \leq j \leq N-1 \\
\rho_N &= \left(\frac{p}{q}\right)^{N-1}
\end{aligned}$$

and the normalizing constant is $c = \sum_{j=0}^{N} \rho_j$. This DTMC is periodic and hence these π_j represent the long run fraction of the time the DTMC spends in state j. Here $\lim_{n\to\infty} Pr(X_n = j \mid X_0 = i)$ does not exist since the probabilities under question keep oscillating with period 2.

2. For the DTMC in Example 1 of §7.7.1, $C_1 = \{1,2\}$, $C_2 = \{3,4\}$, $C_3 = \{5\}$, and $T = \{6\}$. Therefore, $\pi_1 = \frac{7}{13}$, $\pi_2 = \frac{6}{13}$, $\pi_3 = \frac{1}{2}$, $\pi_4 = \frac{1}{2}$, $\pi_5 = 1$, $\alpha_{61} = \frac{2}{5}$, $\alpha_{62} = \frac{2}{5}$, $\alpha_{63} = \frac{1}{5}$. By Fact 4 the limiting matrix (π_{ij}) is given by

$$\begin{pmatrix} \frac{7}{13} & \frac{6}{13} & 0 & 0 & 0 & 0 \\ \frac{7}{13} & \frac{6}{13} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ \frac{14}{65} & \frac{12}{65} & \frac{1}{5} & \frac{1}{5} & \frac{1}{5} & 0 \end{pmatrix}.$$

States 3 and 4 are periodic, and hence the third and fourth columns need to be interpreted as the long run fraction of the time the discrete-time Markov chain spends in those states.

3. The Ehrenfest diffusion model (§7.7.1, Example 6) is an irreducible DTMC with period 2. The solution π (Fact 1) is given by $\pi_j = \binom{M}{j}2^{-M}$ $(0 \le j \le M)$. The binomial distribution (§7.3.1) describes the long run fraction of time the system spends in each state.

7.7.5 FIRST PASSAGE TIMES

Definitions:

Let $\{X_n \mid n \ge 0\}$ be a DTMC on state space S with transition probability matrix P. Let $A \subseteq S$ be a given subset of states.

The ***first passage time*** T_A into set A is the first time at which the Markov chain reaches some state in set A; i.e., $T_A = \min\{n \ge 0 \mid X_n \in A\}$.

For $i \in S$, let $\alpha_i = Pr(T_A < \infty \mid X_0 = i)$ and let $\tau_i = E(T_A \mid X_0 = i)$.

Facts:

1. The $\{\alpha_i\}$ are given by the unique solution to

$$\alpha_i = \sum_{j \in S} p_{ij}\alpha_j$$

with the boundary conditions $\alpha_i = 1$ if $i \in A$ and $\alpha_i = 0$ if no state in A is accessible from i.

2. If $\alpha_i = 1$ for all $i \in S$, then $\{\tau_i\}$ are given by the unique solution to

$$\tau_i = 1 + \sum_{j \in S} p_{ij}\tau_j$$

with the boundary condition $\tau_i = 0$ if $i \in A$.

Examples:

1. Consider the DTMC in §7.7.1, Example 2 with $A = \{0\}$. The equations of Fact 1 are $\alpha_i = q\alpha_{i-1} + p\alpha_{i+1}$, $1 \le i \le N-1$ with the boundary conditions $\alpha_0 = 1$ and $\alpha_N = 0$. If $q \ne p$, the solution is given by

$$\alpha_i = \frac{(\frac{q}{p})^i - (\frac{q}{p})^N}{1-(\frac{q}{p})^N}, \quad 0 \le i \le N.$$

If $q = p$, the solution is $\alpha_i = 1 - \frac{i}{N}$.

2. Consider the DTMC in §7.7.1, Example 2 with $A = \{0, N\}$. In this case $\alpha_i = 1$ for all i. The equations of Fact 2 are $\tau_i = 1 + q\tau_{i-1} + p\tau_{i+1}$, $1 \leq i \leq N-1$, with the boundary conditions $\tau_0 = 0$ and $\tau_N = 0$. If $q \neq p$, the solution is given by

$$\tau_i = \tfrac{i}{q-p} - \tfrac{N}{q-p}\tfrac{1-(\frac{q}{p})^i}{1-(\frac{q}{p})^N}, \quad 0 \leq i \leq N.$$

If $q = p$, the solution is given by $\tau_i = i(N-i)$.

7.7.6 BRANCHING PROCESSES

Branching processes are a special type of Markov chain used to study the growth (and possible extinction) of populations in biology and sociology as well as particles in physics.

Definitions:

Suppose $\{Y_{ni} \mid n, i \geq 1\}$ are independent and identically distributed random variables having common probability distribution function $p_k = Pr(Y_{ni} = k)$, $k \geq 0$, with mean m and variance σ^2. Then the DTMC $\{X_n \mid n \geq 0\}$ is a ***branching process*** if $X_0 = 1$, $X_{n+1} = \sum_{i=1}^{X_n} Y_{ni}$.

A branching process is ***stable*** if $m < 1$, ***critical*** if $m = 1$, and ***unstable*** if $m > 1$.

The ***extinction probability*** of a branching process is the probability that the population becomes extinct, where $X_0 = 1$.

Facts:

1. It is convenient to think of the random variable X_n as the number of individuals in the nth generation and the random variable Y_{ni} as the number of offspring of the ith individual in the nth generation.

2. The transient behavior of the branching process is given by

$$E(X_n) = m^n,$$

$$\text{Var}(X_n) = \begin{cases} n\sigma^2, & \text{if } m = 1 \\ \sigma^2 m^{n-1}\dfrac{m^n - 1}{m-1}, & \text{if } m \neq 1. \end{cases}$$

3. State 0 is absorbing for a branching process. Absorption in state 0 is certain if and only if $m \leq 1$, while the expected time until extinction (i.e., absorption in state 0) is finite if and only if $m < 1$.

4. The probability of extinction ρ in an unstable branching process is given by the unique solution in $(0, 1)$ to the equation

$$\rho = \sum_{n=0}^{\infty} p_n \rho^n.$$

5. The expected total number of individuals ever born in a stable branching process until it becomes extinct is given by

$$E(\sum_{n=0}^{\infty} X_n) = \frac{1}{1-m}.$$

6. There is no simple expression for the expected time until absorption for a general stable branching process.

Examples:

1. The branching process with $p_0 = \frac{1}{2}$, $p_1 = \frac{1}{8}$, $p_2 = \frac{3}{8}$ has mean $m = \frac{7}{8} < 1$ and is stable. With probability 1, the population will die out.

2. The branching process with $p_0 = \frac{1}{4}$, $p_1 = \frac{1}{4}$, $p_2 = \frac{1}{2}$ has mean $m = \frac{5}{4} > 1$ and is unstable. The probability of extinction ρ_0 is found as the smallest positive root of the equation $\rho = \frac{1}{4} + \frac{1}{4}\rho + \frac{1}{2}\rho^2$. The roots of this equation are $\frac{1}{2}$ and 1, so the probability of extinction is $\rho_0 = \frac{1}{2}$. If the initial population is $X_0 = 10$ instead of $X_0 = 1$, then the probability that the initial population eventually becomes extinct is $\rho_0^{10} = \frac{1}{1024}$.

7.8 HIDDEN MARKOV MODELS

A Hidden Markov Model (HMM) is a statistical tool used in modeling discrete-time stochastic systems. The theory of HMMs assumes that the system under consideration has only a finite number of states. Still the HMM is a very powerful tool because of its dual stochastic nature (i.e., the probabilistic modeling of both inter-state transitions and intra-state processes). This property makes it suitable for modeling systems that change their statistical properties over time. HMMs are widely used in speech recognition and have found applications in several other areas such as bioinformatics, gene sequence modeling, economic/financial analysis, speech synthesis, and web usage analysis.

7.8.1 BASIC CONCEPTS

Definitions:

A ***Hidden Markov Model*** (***HMM***) consists of a finite set $S = \{1, 2, \ldots, N\}$ of ***states***, where each state $j \in S$ is associated with a (generally multidimensional) probability distribution $b_j(o)$. In a particular state, at a given time $t \geq 1$, an outcome or ***observation*** o_t can be generated, according to the associated probability distribution.

Transitions among the states are governed by a set of ***transition probabilities*** $a_{ij} = Pr(q_{t+1} = j | q_t = i)$, where $q_t \in S$ is a random variable denoting the state at time t. The matrix $A = (a_{ij})$ is the ***transition probability matrix*** of the HMM.

The ***initial state distribution*** of the HMM is the vector $\pi = (\pi_i)$, where $\pi_i = Pr(q_1 = i)$, $i \in S$.

While a transition from q_t to the next state q_{t+1} can in general depend on all past states, the model is simplified by truncating the dependency to only the past k states. This gives a ***kth-order HMM*** in which $Pr(q_{t+1} = j | q_t = i_t, q_{t-1} = i_{t-1}, \ldots, q_{t-k+1} = i_{t-k+1}) = Pr(q_{t+1} = j | q_t = i_t, q_{t-1} = i_{t-1}, \ldots, q_1 = i_1)$, where $i_1, i_2, \ldots, i_t, j \in S$. If $k = 1$, this HMM has the ***Markov property***:

$$a_{ij} = Pr(q_{t+1} = j | q_t = i) = Pr(q_{t+1} = j | q_t = i_t, q_{t-1} = i_{t-1}, \ldots, q_1 = i_1),$$

for all $i_1, i_2, \ldots, i_t, j \in S$.

The HMM is ***stationary*** or ***time homogeneous*** if $Pr(q_{s+1} = j | q_s = i) = Pr(q_{t+1} = j | q_t = i)$ for all $s, t \geq 1$.

The HMM has the ***conditional independence property*** if $Pr(O|q_1, q_2, \ldots, q_T, \lambda) = \prod_{t=1}^{T} Pr(o_t|q_t, \lambda)$, where $O = (o_1, o_2, \ldots, o_T)$ is a sequence of observations, $q_t \in S$, and λ denotes the parameter set of the HMM.

The HMM is a ***Discrete Hidden Markov Model*** (***DHMM***) if all the observations it can generate can be drawn from a finite set. That is, $o_t \in \{\nu_1, \nu_2, \ldots, \nu_M\}$ for all $t \geq 1$, where ν_k, $k \in \mathcal{M} = \{1, 2, \ldots, M\}$, denotes the kth observation symbol in the alphabet. Then the probability distribution associated with each state can be represented by the finite set of probabilities $b_j(o) = b_{jk} = Pr(o = \nu_k|q_t = j)$, where $j \in S$, $k \in \mathcal{M}$, and o is the current observation. The matrix $B = (b_{jk})$ is termed the ***observation probability matrix*** of the DHMM.

The HMM is a ***Continuous Density Hidden Markov Model*** (***CDHMM***) if it can generate all the observations within a given (finite or infinite) interval. In this case the observation probability distribution can be modeled analytically using a density function such as a multidimensional Gaussian distribution

$$N(\mu, \Sigma, o) = (2\pi)^{-\frac{D}{2}} |\Sigma|^{-\frac{1}{2}} \exp\left(-\tfrac{1}{2}(o-\mu)^T \Sigma^{-1}(o-\mu)\right)$$

where D is the dimension of the observation vector, μ is the distribution mean, and Σ is the distribution covariance matrix.

Facts:

1. A discrete-time Markov chain (DTMC) [see §7.7] can be extended to an HMM by associating a probability distribution with each state of the DTMC.

2. Unlike a DTMC, in the case of an HMM, only the outcome o_t, not the state q_t, is visible to an external observer and therefore states are "hidden" to the outside. This accounts for the name *Hidden Markov Model.*

3. A DHMM can be completely defined by the 3-tuple $\lambda = (A, B, \pi)$, where A, B, and π are the transition probability matrix, the observation probability matrix, and the initial state distribution, respectively.

4. For a CDHMM a weighted sum of a finite number M of Gaussians is often used to model the distributions $b_j(o)$ as

$$b_j(o) = \sum_{m=1}^{M} c_{jm} N(\mu_{jm}, \Sigma_{jm}, o)$$

for all $j \in S$, where c_{jm}, $m \in \mathcal{M}$, is the weighting coefficient.

5. A CDHMM can be completely defined by the 5-tuple $\lambda = (A, C, \mu^*, \Sigma^*, \pi)$, where A and π are as in Fact 3, and the weighting coefficient matrix, the set of mean vectors, and the set of covariance matrices are given by $C = (c_{jm})$, $\mu^* = \{\mu_{jm}|j \in S, m \in \mathcal{M}\}$, and $\Sigma^* = \{\Sigma_{jm}|j \in S, m \in \mathcal{M}\}$.

6. The initial state probabilities satisfy $\sum_{i=1}^{N} \pi_i = 1$.

7. The transition probabilities satisfy $a_{ij} \geq 0,\ i, j \in S$ and $\sum_{j=1}^{N} a_{ij} = 1,\ i \in S$.

8. The observation probabilities for a DHMM satisfy $b_{jk} \geq 0,\ j \in S,\ k \in \mathcal{M}$ and $\sum_{k=1}^{M} b_{jk} = 1,\ j \in S$.

9. The weighting coefficients for a CDHMM satisfy $c_{jm} \geq 0,\ j \in S,\ m \in M$ and $\sum_{m=1}^{M} c_{jm} = 1,\ j \in S$.

Examples:

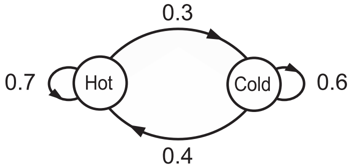
1. Suppose that an experimenter tosses one of three (possibly biased) coins and reports to the observer only the outcome Heads (H) or Tails (T). This situation can be modeled as a DHMM in which the state j refers to coin j, which has probability p_j of producing Heads. The experimenter successively chooses coins according to a DTMC with transition probabilities a_{ij}, where $i, j \in \{1, 2, 3\}$. For coin j the observation probabilities for H and T are $b_j(H) = p_j$ and $b_j(T) = 1 - p_j$, respectively. This DHMM has $N = 3$ states and $M = 2$ observation symbols.

2. Suppose that there are N urns, each containing some mix of M colored balls. At each time step, a ball is randomly selected from one of the urns and its color is revealed to the observer. The ball is then returned to that urn. However, the observer does not know what urn was sampled.

This situation can be modeled as a DHMM in which the state corresponds to the urn sampled, with state transition probabilities indicating the next urn sampled. For a given urn, the mixture of colors dictates the observation probabilities for the M possible colors. Notice that the states (urns) are hidden from view, and one only is allowed to observe the color drawn.

3. Suppose that we are interested in determining overall annual temperatures (Hot or Cold) at a specific location at some point in the distant past. However, we do not have records of the temperatures (say over T years) but do have samples of trees harvested (and preserved) over that time period. In particular, we can observe the size of tree rings $o_1, o_2, \ldots, o_T$ over that time period, where each $o_t \in \{\text{small, medium, large}\}$. It is reasonable that temperature (Hot, Cold) may follow a 2-state DTMC, with transition probabilities indicating that hot years are more likely to follow hot years, and similarly for cold years. Likewise, the size of tree rings may be presumed to be correlated with overall annual temperature. This situation can be modeled as a DHMM, since we only observe the size of tree rings, but not the state of the system (temperature).

As a specific example, the following figure shows the state transition diagram for the Markov chain on states Hot and Cold. Below this are the corresponding columns of the matrix $B = (b_{jk})$. The observations o_1, o_2, o_3 indicate respectively the ring sizes (small, medium, large).



$$\begin{array}{cc} & \text{Hot} \\ \begin{array}{c}1\\2\\3\end{array} & \begin{bmatrix}0.1\\0.4\\0.5\end{bmatrix}\end{array} \qquad \begin{array}{cc} & \text{Cold} \\ \begin{array}{c}1\\2\\3\end{array} & \begin{bmatrix}0.6\\0.3\\0.1\end{bmatrix}\end{array}$$

7.8.2 THE EVALUATION PROBLEM

This subsection discusses the problem of determining the likelihood of obtaining the observed data, given the specification of the parameters of some given HMM. This provides a measure for scoring how well a particular model matches the observation sequence. For simplicity, the focus here is on DHMMs, with specified parameter set $\lambda = (A, B, \pi)$.

Definitions:

Assume that a given sequence of observations $O = (o_1, o_2, \dots, o_T)$ has been generated by a given HMM with parameter set λ. The ***evaluation problem*** consists of determining the probability $Pr(O|\lambda)$.

A ***state*** Q of the system is given by $Q = (q_1, q_2, \dots q_T)$ and the set of all system states is denoted Ω. ***Direct evaluation*** of $Pr(O|\lambda)$ is obtained by enumerating all states of the system: $Pr(O|\lambda) = \sum_{Q\in\Omega} Pr(O, Q|\lambda) = \sum_{Q\in\Omega} Pr(O|Q, \lambda)\, Pr(Q|\lambda)$.

The ***forward algorithm*** for computing $Pr(O|\lambda)$ makes use of the ***forward variables*** $\alpha_t(i) = Pr(o_1, o_2, \dots, o_t, q_t = i|\lambda)$, which can be interpreted as the probability of the partial observation sequence $o_1, o_2, \dots, o_t$, when it terminates at the state i.

The ***backward algorithm*** for computing $Pr(O|\lambda)$ makes use of the ***backward variables*** $\beta_t(i) = Pr(o_{t+1}, o_{t+2}, \dots, o_T|q_t = i, \lambda)$, which can be interpreted as the probability of the partial observation sequence $o_{t+1}, o_{t+2}, \dots, o_T$, given that the current state is i.

Facts:

1. In the direct evaluation method, $Pr(Q|\lambda)$ can be calculated using π and A.

2. In the direct evaluation method, $Pr(O|Q, \lambda)$ can be calculated using B.

3. Since the state space Ω has size $O(N^T)$, direct evaluation of $Pr(O|\lambda)$ has $O(TN^T)$ computational complexity and so is feasible only if N and T are very small.

4. The forward variables $\alpha_t(j)$ satisfy the recursive relationship

$$\alpha_{t+1}(j) = b_j(o_{t+1}) \sum_{i=1}^{N} \alpha_t(i) a_{ij}, \;\; j \in S, \;\; t \in \{1, 2, \dots, T-1\},$$

with $\alpha_1(j) = \pi_j b_j(o_1), \;\; j \in S$.

5. The conditional probability of the observation sequence given the HMM is related to the forward variables through

$$Pr(O|\lambda) = \sum_{i=1}^{N} Pr(o_1, o_2, \dots, o_T, q_T = i|\lambda) = \sum_{i=1}^{N} \alpha_T(i).$$

6. The forward algorithm, shown as Algorithm 1, is based on Facts 4 and 5.

```
Algorithm 1: Forward algorithm.
 input: $A, B, \pi$
 output: $Pr(O|\lambda)$
 for $j := 1$ to $N$
   $\alpha_1(j) := \pi_j b_j(o_1)$
 for $t := 1$ to $T - 1$
   for $j := 1$ to $N$
     $\alpha_{t+1}(j) := b_j(o_{t+1}) \sum_{i=1}^{N} \alpha_t(i) a_{ij}$
 $Pr(O|\lambda) := \sum_{i=1}^{N} \alpha_T(i)$
```

7. The computational complexity of the forward algorithm is $O(N^2T)$, which is linear in T compared to the exponential complexity of direct evaluation (Fact 3).

8. The backward variables $\beta_t(i)$ satisfy the recursive relationship

$$\beta_t(i) = \sum_{j=1}^{N} \beta_{t+1}(j) a_{ij} b_j(o_{t+1}),\ i \in S,\ t \in \{T-1, T-2, \dots, 1\},$$

with $\beta_T(i) = 1,\ i \in S$.

9. The conditional probability of the observation sequence given the HMM is related to the backward variables through

$$Pr(O|\lambda) = \sum_{i=1}^{N} \pi_i b_i(o_1) \beta_1(i)$$

since

$$\begin{aligned} \pi_i b_i(o_1)\beta_1(i) &= Pr(q_1 = i)\, Pr(o_1|q_1 = i)\, Pr(o_2, o_3, \dots, o_T|q_1 = i, \lambda) \\ &= Pr(o_1, o_2, \dots, o_T, q_1 = i|\lambda). \end{aligned}$$

10. The backward algorithm, shown as Algorithm 2, is based on Facts 8 and 9.

```
Algorithm 2: Backward algorithm.
 input: $A, B, \pi$
 output: $Pr(O|\lambda)$
 for $i := 1$ to $N$
   $\beta_T(i) := 1$
 for $t := T - 1$ to $1$
   for $i := 1$ to $N$
     $\beta_t(i) := \sum_{j=1}^{N} \beta_{t+1}(j) a_{ij} b_j(o_{t+1})$
 $Pr(O|\lambda) := \sum_{i=1}^{N} \pi_i b_i(o_1) \beta_1(i)$
```

11. The computational complexity of the backward algorithm is also $O(N^2T)$.

12. Using the definitions of $\alpha_t(i)$ and $\beta_t(i)$ together with the conditional independence assumption, it can be shown that

$$\alpha_t(i)\beta_t(i) = Pr(O, q_t = i|\lambda),\ i \in S,\ t \in \{1, 2, \ldots, T\}.$$

13. Fact 11 gives another way to calculate $Pr(O|\lambda)$, using both forward and backward variables:

$$Pr(O|\lambda) = \sum_{i=1}^{N} Pr(O, q_t = i|\lambda) = \sum_{i=1}^{N} \alpha_t(i)\beta_t(i),\ t \in \{1, 2, \ldots, T\}.$$

Examples:

1. We use the direct evaluation approach to calculate the probability of observing the sequence (medium, large, small) for Example 3 in §7.8.1. For ease of representation, the observations are encoded using small = 1, medium = 2, and large = 3, so the observed sequence is $2, 3, 1$. Also, we encode the states as Hot = 1 and Cold = 2. In this problem, the initial state probabilities $\pi = (0.8, 0.2)$ are used.

To illustrate, for state Q = Hot Hot Cold = 112, we calculate $Pr(Q|\lambda) = Pr(112|\lambda) = (0.8)(0.7)(0.3) = 0.168$ and $Pr(O|Q, \lambda) = Pr(231|Q, \lambda) = (0.4)(0.5)(0.6) = 0.12$. Consequently, $Pr(O, Q|\lambda) = Pr(O|Q, \lambda)\,Pr(Q|\lambda) = (0.12)(0.168) = 0.02016$. Similar calculations are shown in the following table. Adding the entries in the last column gives $Pr(O|\lambda) = 0.03628$.

Q	$Pr(Q\|\lambda)$	$Pr(O\|Q,\lambda)$	$Pr(O,Q\|\lambda)$
111	0.392	0.02	0.00784
112	0.168	0.12	0.02016
121	0.096	0.004	0.000384
122	0.144	0.024	0.003456
211	0.056	0.015	0.00084
212	0.024	0.09	0.00216
221	0.048	0.003	0.000144
222	0.072	0.018	0.001296

2. We illustrate the application of the forward algorithm to the same problem studied in Example 1.

$\alpha_1(1) = \pi_1 b_1(2) = (0.8)(0.4) = 0.32$, $\alpha_1(2) = \pi_2 b_2(2) = (0.2)(0.3) = 0.06$;

$\alpha_2(1) = b_1(3)[\alpha_1(1)a_{11} + \alpha_1(2)a_{21}] = 0.5[(0.32)(0.7) + (0.06)(0.4)] = 0.124$;

$\alpha_2(2) = b_2(3)[\alpha_1(1)a_{12} + \alpha_1(2)a_{22}] = 0.1[(0.32)(0.3) + (0.06)(0.6)] = 0.0132$;

$\alpha_3(1) = b_1(1)[\alpha_2(1)a_{11} + \alpha_2(2)a_{21}] = 0.1[(0.124)(0.7) + (0.0132)(0.4)] = 0.009208$;

$\alpha_3(2) = b_2(1)[\alpha_2(1)a_{12} + \alpha_2(2)a_{22}] = 0.6[(0.124)(0.3) + (0.0132)(0.6)] = 0.027072$.

As a result, $Pr(O|\lambda) = 0.009208 + 0.027072 = 0.03628$.

3. We illustrate the application of the backward algorithm to the same problem studied in Example 1.

$\beta_3(1) = 1$, $\beta_3(2) = 1$;

$\beta_2(1) = \beta_3(1)a_{11}b_1(o_3) + \beta_3(2)a_{12}b_2(o_3) = 1(0.7)(0.1) + 1(0.3)(0.6) = 0.25$;

$\beta_2(2) = \beta_3(1)a_{21}b_1(o_3) + \beta_3(2)a_{22}b_2(o_3) = 1(0.4)(0.1) + 1(0.6)(0.6) = 0.4$;

$$\beta_1(1) = \beta_2(1)a_{11}b_1(o_2)+\beta_2(2)a_{12}b_2(o_2) = (0.25)(0.7)(0.5)+(0.4)(0.3)(0.1) = 0.0995;$$
$$\beta_1(2) = \beta_2(1)a_{21}b_1(o_2)+\beta_2(2)a_{22}b_2(o_2) = (0.25)(0.4)(0.5)+(0.4)(0.6)(0.1) = 0.074.$$

Then $Pr(O|\lambda) = \pi_1 b_1(o_1)\beta_1(1)+\pi_2 b_2(o_1)\beta_1(2) = (0.8)(0.4)(0.0995)+(0.2)(0.3)(0.074) = 0.03628$.

7.8.3 THE DECODING PROBLEM

This subsection discusses the problem of finding a state sequence that best explains the observed data, given the specification of the parameters of an HMM. The focus here is on DHMMs, with parameter set $\lambda = (A, B, \pi)$.

Definitions:

Given an HMM with parameter set λ and a sequence of observations $O = (o_1, o_2, \dots, o_T)$, the ***decoding problem*** deals with finding a state sequence $Q = (q_1.q_2, \dots, q_T)$ that maximizes the conditional probability $Pr(Q|O, \lambda)$.

The ***direct approach*** to the decoding problem proceeds by calculating $Pr(Q|O, \lambda)$ for all possible state sequences and picking one that achieves the highest value.

The ***Viterbi algorithm*** for solving the decoding problem makes use of the auxiliary variable

$$\delta_t(i) = \max_{q_1,q_2,\dots,q_{t-1}} Pr(q_1, q_2, \dots, q_{t-1}, q_t = i, o_1, o_2, \dots, o_t|\lambda),$$

which is the largest joint probability that the partial observation sequence and the state sequence can have up to time t, when the current state is i.

Facts:

1. Since the observation sequence O is given, the decoding problem can be solved by finding a state sequence Q that maximizes the joint probability $Pr(Q, O|\lambda)$.

2. Since the state space Ω has size $O(N^T)$, the direct approach has exponential complexity.

3. From the Markov property and the conditional independence property of the HMM, the following recursion holds:

$$\delta_{t+1}(j) = b_j(o_{t+1})[\max_{i=1,\dots,N} \delta_t(i)a_{ij}\,],\ j \in S,\ t \in \{1, 2, \dots, T-1\},$$

with $\delta_1(j) = \pi_j b_j(o_1),\ j \in S$.

4. The Viterbi algorithm (Algorithm 3), based on Facts 1 and 3, produces a state sequence Q^* that maximizes the joint probability $Pr(Q, O|\lambda)$.

```
Algorithm 3: Viterbi algorithm.
  input: $A, B, \pi, O$
  output: state $Q^* = (q_1^*, q_2^*, \dots, q_T^*)$ that maximizes $Pr(Q, O|\lambda)$, and the maximum
    joint probability $p^*$.
  for $j := 1$ to $N$
    $\delta_1(j) := \pi_j b_j(o_1)$
    $\psi_1(j) := 0$
```

```
for $t := 1$ to $T - 1$
  for $j := 1$ to $N$
    $\delta_{t+1}(j) := b_j(o_{t+1})[\max_{i=1,\ldots,N} \delta_t(i)a_{ij}]$
    $\psi_{t+1}(j) := \text{argmax}_{i=1,\ldots,N} \delta_t(i)a_{ij}$
$p^* := \max_{j=1,\ldots,N} \delta_T(j)$
$q_T^* := \text{argmax}_{j=1,\ldots,N} \delta_T(j)$
for $t := T$ to 2   {Backtrack to find the state $Q^*$}
  $q_{t-1}^* := \psi_t(q_t^*)$
$Q^* = (q_1^*, q_2^*, \ldots, q_T^*)$
```

5. Algorithm 3 uses the predecessor array ψ in order to retrieve a state sequence that achieves the maximum joint probability p^*.

6. Algorithm 3 has $O(N^2T)$ complexity.

7. Calculations in the Viterbi algorithm are quite similar to those in the forward algorithm, except that the *max* operator is applied within the main loop as opposed to the *summation* operator.

8. Algorithm 3 can be interpreted as a search in an acyclic network whose nodes are formed by the states of the HMM at each time instant $t \in \{1, 2, \ldots, T\}$.

Examples:

1. We use the direct evaluation approach to calculate a state sequence Q^* that maximizes the joint probability $Pr(Q, O|\lambda)$, where $O = 231$. The last column of the table shown in Example 1 of §7.8.2 displays the joint probabilities $Pr(Q, O|\lambda)$. The maximum such probability is then 0.02016, achieved by the state sequence $Q^* = 112$, which corresponds to the sequence of temperatures Hot Hot Cold.

2. We illustrate the application of the Viterbi algorithm to the same problem studied in Example 1.

$$\delta_1(1) = \pi_1 b_1(2) = (0.8)(0.4) = 0.32,\ \delta_1(2) = \pi_2 b_2(2) = (0.2)(0.3) = 0.06;$$

$$\delta_2(1) = b_1(3)\max[\delta_1(1)a_{11}, \delta_1(2)a_{21}] = 0.5\max[0.224, 0.024] = 0.112,\ \psi_2(1) = 1;$$

$$\delta_2(2) = b_2(3)\max[\delta_1(1)a_{12}, \delta_1(2)a_{22}] = 0.1\max[0.096, 0.036] = 0.0096,\ \psi_2(2) = 1;$$

$$\delta_3(1) = b_1(1)\max[\delta_2(1)a_{11}, \delta_2(2)a_{21}] = 0.1\max[0.0784, 0.00384] = 0.00784,\ \psi_3(1) = 1;$$

$$\delta_3(2) = b_2(1)\max[\delta_2(1)a_{12}, \delta_2(2)a_{22}] = 0.6\max[0.0336, 0.00576] = 0.02016,\ \psi_3(2) = 1.$$

So the maximum joint probability is $p^* = \max[\delta_3(1), \delta_3(2)] = \max[0.00784, 0.02016)] = 0.02016$. Also $q_3^* = 2$, $q_2^* = \psi_3(q_3^*) = \psi_3(2) = 1$, $q_1^* = \psi_2(q_2^*) = \psi_2(1) = 1$, giving $Q^* = 112$.

7.8.4 THE LEARNING PROBLEM

This subsection discusses the problem of optimizing the model parameters $\lambda = (A, B, \pi)$ of an HMM to best describe a given sequence of observations. This problem arises in "training" an HMM in order to mimic the observed behavior of a system.

Definitions:

Let the HMM have parameter set $\lambda = (A, B, \pi)$ and suppose the sequence of observations $O = (o_1, o_2, \ldots, o_T)$ is given. The ***learning problem*** deals with adjusting the model parameters λ in order to maximize $L = Pr(O|\lambda)$.

While there is no known way to analytically solve this problem, there are iterative procedures that adjust the model parameters so that L is locally maximized. The ***Baum-Welch algorithm*** is such a procedure which makes use of the auxiliary variables $\xi_t(i,j) = Pr(q_t = i, q_{t+1} = j|O, \lambda)$ and $\gamma_t(i) = Pr(q_t = i|O, \lambda)$.

Here $\xi_t(i,j)$ is the probability of being in state i at time t and in state j at time $t+1$, whereas $\gamma_t(i)$ is the a posteriori probability of being in state i at time t, given the observation sequence and the model.

Facts:

1. The Baum-Welch algorithm, also known as the *forward-backward* algorithm, can be derived using arguments of occurrence counting between q_t and q_{t+1}.

2. The Baum-Welch algorithm is a special case of the well-known *Expectation Maximization (EM)* method. It is guaranteed to converge to at least a local maximum.

3. The following relationship holds:

$$\xi_t(i,j) = \frac{Pr(q_t = i, q_{t+1} = j, O|\lambda)}{Pr(O|\lambda)} = \frac{\alpha_t(i) a_{ij} \beta_{t+1}(j) b_j(o_{t+1})}{\sum_{\ell=1}^{N} \sum_{m=1}^{N} \alpha_t(\ell) a_{\ell m} \beta_{t+1}(m) b_m(o_{t+1})},$$

where $i, j \in S$ and $t \in \{1, 2, \ldots, T-1\}$.

4. The relationship between $\gamma_t(i)$ and $\xi_t(i,j)$ is given by

$$\gamma_t(i) = \sum_{j=1}^{N} \xi_t(i,j), \;\; i \in S, \;\; t \in \{1, 2, \ldots, T-1\}.$$

5. Using Facts 3 and 4, the Baum-Welch algorithm can be constructed as shown in Algorithm 4.

```
Algorithm 4: Baum-Welch algorithm.
  input: $\lambda = (A, B, \pi)$, $O$
  output: $\overline{\lambda} = (\overline{A}, \overline{B}, \overline{\pi})$ that maximizes $Pr(O|\overline{\lambda})$
  initialize $\lambda_0$ to a set of random values
  while $Pr(O|\lambda) - Pr(O|\lambda_0) > \epsilon$
    run the forward algorithm to find $\alpha_t(i)$ for all $i \in S$ and $t \in \{1, 2, \ldots, T\}$
    run the backward algorithm to find $\beta_t(i)$ for all $i \in S$ and $t \in \{1, 2, \ldots, T\}$
    for $i := 1$ to $N$
      for $j := 1$ to $N$
        for $t := 1$ to $T - 1$
          $\xi_t(i,j) := \frac{\alpha_t(i) a_{ij} \beta_{t+1}(j) b_j(o_{t+1})}{\sum_{\ell=1}^{N} \sum_{m=1}^{N} \alpha_t(\ell) a_{\ell m} \beta_{t+1}(m) b_m(o_{t+1})}$
    for $i := 1$ to $N$
      for $t := 1$ to $T - 1$
        $\gamma_t(i) := \sum_{j=1}^{N} \xi_t(i,j)$
    for $i := 1$ to $N$
      $\overline{\pi}_i := \gamma_1(i)$
    for $i := 1$ to $N$
      for $j := 1$ to $N$
        $\overline{a}_{ij} := \dfrac{\sum\{\xi_t(i,j) : t = 1,\dots,T-1\}}{\sum\{\gamma_t(i) : t = 1,\dots,T-1\}}$
    for $j := 1$ to $N$
      for $k := 1$ to $M$
        $\overline{b}_j(k) := \dfrac{\sum\{\gamma_t(j) : t = 1,\dots,T-1; O_t = \nu_k\}}{\sum\{\gamma_t(j) : t = 1,\dots,T-1\}}$
    $\overline{A} := (\overline{a}_{ij})$, $\overline{B} := (\overline{b}_j(k))$, $\overline{\pi} := (\overline{\pi}_i)$
    $\overline{\lambda} := (\overline{A}, \overline{B}, \overline{\pi})$, $\lambda_0 := \lambda$
    $\lambda := \overline{\lambda}$
  return $\overline{\lambda}$
```

7.9 QUEUEING THEORY

Queueing theory provides a set of tools for the analysis of systems in which customers arrive at a service facility. It has its origins in the works of A. K. Erlang (starting in 1908) in telephony. Since then it has found many applications in diverse areas such as manufacturing, inventory systems, computer science, analysis of algorithms, and telecommunications. Although queueing theory uses the terminology of servers providing service to customers, in actual applications the customers may be people, jobs, computational steps, or messages, and the servers may be human beings, machines, telephone circuits, communication channels, or computers.

7.9.1 SINGLE-STATION QUEUES

The simplest queueing system is a single-station queue in which customers arrive, wait for service, and depart after service completion. In this and subsequent sections we restrict ourselves to single-station queues.

Definitions:

A ***queueing system*** consists of a set of ***customers***, who arrive at a service facility according to a specified ***arrival process***. If a server is available then the customer is served immediately, with the length of time required to carry out the service determined by a ***service-time distribution***. If a server is not free, the customer joins the ***queue*** and is later served according to a ***service discipline***, which specifies the order in which customers are selected for service from the queue. Throughout, the service discipline is assumed to be First-Come-First-Served (FCFS). Alternative service disciplines include Last-Come-First-Served, randomly, or according to a tiered priority scheme.

The ***queue capacity*** is the maximum number of customers allowed in the system, either being served or awaiting service. Unless otherwise specified, the queue capacity is assumed to be infinite.

In a ***single-station*** queueing system, customers arrive, wait for service, and depart after service completion.

An ***exponential distribution*** with parameter λ is a density function (§7.3.1) having the form $f(x) = \lambda e^{-\lambda x}$ for $x \geq 0$.

An arrival process is ***Poisson*** if the interarrival times (times between successive arrivals) are independent and identically distributed exponential random variables.

A random variable has an ***Erlang distribution*** with phase parameter k if it is the sum of $k \geq 1$ independent and identically distributed exponential random variables.

Facts:

1. If the random variable X has an exponential distribution with parameter λ, then $E(X) = \frac{1}{\lambda}$ and $\mathrm{Var}(X) = \frac{1}{\lambda^2}$.

2. If the arrival process is Poisson with parameter λ, then the number of customers arriving in an interval of time of length x is a Poisson random variable (§7.3.1) with parameter λx.

3. The Erlang distribution is a special type of gamma distribution (§7.3.1).

4. *Kendall's notation*: A single-station queueing system can be described by the 5-tuple interarrival-time distribution/service-time distribution/number of servers/waiting room capacity/service discipline.

5. The following symbols are standard in describing queueing systems according to the scheme in Fact 4.

- M — exponential (M for Memoryless);
- E_k — Erlang with phase parameter k;
- D — deterministic (constant);
- G — general.

6. More complicated queueing systems can consist of networks of queues, multiple types of customers, and priority schemes.

7. A list of over 300 books on queueing theory can be found at

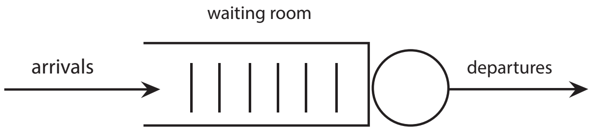
- `http://web2.uwindsor.ca/math/hlynka/qbook.html`

8. A compilation of queueing theory software can be found at

- `http://web2.uwindsor.ca/math/hlynka/qsoft.html`

Examples:

1. A single-station queueing system is depicted by the schematic diagram in the following figure. Here customers randomly join the system (according to the arrival process), wait for service in the waiting room, are served (which takes a random amount of time), and then depart from the system.



2. An $M/G/3/10/\text{LCFS}$ system has Poisson arrivals (exponential interarrival times), general service times, three servers, room for ten customers (including those in service), and Last-Come-First-Served service discipline.

3. An $M/M/1$ queue has Poisson arrivals, exponential service times, a single server, infinite waiting room, and FCFS service discipline.

4. *Airplane landings*: The landing of aircraft at an airport can be viewed as a queueing system in which the aircraft are the customers and the runways are the servers. Aircraft arrive according to a certain stochastic arrival process, and the length of time to land follows a certain service-time distribution. Those aircraft that are unable to land must join the queue of circling aircraft, awaiting service (normally according to a FCFS discipline, except in the case of an emergency landing, which would be a type of priority scheme).

5. *Communication network*: Messages arrive according to a Poisson process at rate λ per second and are to be transmitted over a particular data link. The time required to transmit a single message is exponentially distributed, with average duration $\frac{1}{\mu}$ seconds. Messages waiting to be sent are stored in an input buffer. If the buffer has infinite capacity, then this system is an $M/M/1$ queue. If the input buffer has finite capacity c, then this system is an $M/M/1/c$ queue.

6. *Banking*: Customers arriving at a bank form a single common queue and are served by the s available tellers in FCFS order. If arrivals are Poisson and the length of time to service a customer is exponential, this system can be modeled as an $M/M/s$ queue.

7. *Call center*: A call center has c operators (servers) available to provide technical assistance to customers calling a central telephone number. Calls are routed to an available agent if one is free; otherwise the caller receives a busy signal. If arrivals are Poisson and the length of time spent on a call follows an arbitrary distribution, then this is an $M/G/c/c$ queue. It is also known as a *loss system*, since any calls to the system receive a busy signal when all servers are occupied, and hence these calls are “lost” to the system.

7.9.2 GENERAL SYSTEMS

This section presents results applicable to single-station queues with general arrival patterns, service-time distributions, and queue disciplines.

Definitions:

For a single-station queueing system, define

- $A_n =$ the arrival time of the nth customer to the system;
- $S_n =$ the service time of the nth customer;
- $D_n =$ the departure time of the nth customer;
- $A(t) =$ the total number of arrivals up to and including time t;
- $D(t) =$ the total number of departures up to and including time t;
- $X(t) =$ the total number of customers waiting in the system at time t.

The stochastic process $\{X(t) \mid t \geq 0\}$ is the ***queue-length process***.

The state distribution following an arbitrary departure is $\pi_j = \lim_{n\to\infty} Pr(X(D_n^+) = j)$, for $j \geq 0$.

The state distribution prior to an arbitrary arrival is $\pi_j^* = \lim_{n\to\infty} Pr(X(A_n^-) = j)$, for $j \geq 0$.

The state distribution at an arbitrary time point, or ***steady-state distribution***, is $p_j = \lim_{t\to\infty} Pr(X(t) = j)$, for $j \geq 0$.

The queue-length process (or the queueing system) is ***stable*** if the steady-state distribution $\{p_j \mid j \geq 0\}$ exists and $\sum_{j=0}^{\infty} p_j = 1$.

The ***waiting time*** of the nth customer is $W_n = D_n - A_n$; it includes the service time.

The steady-state ***expected waiting time*** is $W = \lim_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} W_k$, if the limit exists.

The ***long-run arrival rate*** is $\lambda = \lim_{n\to\infty} \frac{n}{A_n}$, if the limit exists.

The steady-state ***expected number*** in the system is $L = \lim_{t\to\infty} \frac{1}{t} \int_0^t X(u)\, du$, if the limit exists.

Facts:

1. The number of customers in the system at any time equals the total number of arrivals up to that time minus the number of departures up to that time: that is, $X(t) = A(t) - D(t)$ for $t \geq 0$.

2. A sample path of the queue-length process $\{X(t) \mid t \geq 0\}$ is piecewise constant, with upward jumps at points of arrival and downward jumps at points of departure.

3. Suppose all the jumps in the sample paths of $\{X(t) \mid t \geq 0\}$ are of size ±1, with probability 1. If either π_j or π_j^* exists, then $\pi_j = \pi_j^*$ for all $j \geq 0$.

4. *PASTA* (*Poisson Arrivals See Time Averages*): If $\{A(t) \mid t \geq 0\}$ is Poisson and, for every $s \geq 0$, $\{A(t) \mid t \geq s\}$ is independent of $\{X(u) \mid 0 \leq u < s\}$, then $p_j = \pi_j^*$ for all $j \geq 0$.

5. *Little's law* (J. D. C. Little, 1961): $L = \lambda W$.

Examples:

1. Suppose arrivals to a system occur deterministically, every three minutes, and service times are deterministic, each taking two minutes. Since every arriving customer is served immediately, either $X(t) = 0$ (no customers) or $X(t) = 1$ (a single customer). Every arrival finds an empty system and every departure leaves an empty system: $\pi_0 = 1 = \pi_0^*$, $\pi_1 = 0 = \pi_1^*$, as required by Fact 3. (The steady-state distribution does not exist.)

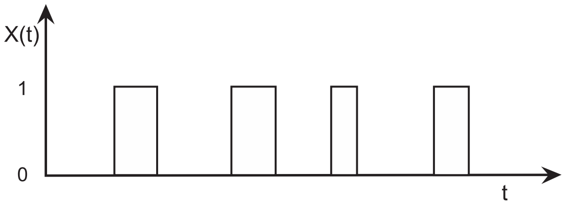
2. On average $\lambda = 24$ customers per hour arrive at a copy shop. Typically, there are $L = 9$ customers in the store at any time. Using Little's law, $W = \frac{L}{\lambda} = 0.375$ hour so that each customer spends on average 0.375 hours (or 22.5 minutes) in the shop.

3. The steady-state queue length or waiting time in a queueing system can be reduced by increasing the service rate. Suppose the long-run arrival rate doubles, but the service rate is increased so that the steady-state expected waiting time remains the same. Then by Little's law the steady-state expected queue length will also double.

4. *Machine repair*: A single machine is either working or being repaired. Suppose that the average time between breakdowns is exponentially distributed with mean $\frac{1}{\lambda}$ and the time to repair the machine is is exponentially distributed with mean $\frac{1}{\mu}$. This is then an $M/M/1/1$ queueing system with a single customer, corresponding to a broken down machine. $X(t) = 0$ signifies that the machine is working, and $X(t) = 1$ signifies that the machine is being repaired. A sample path of this system is shown in the following figure, with the machine initially working. Over a long period of time, after N breakdowns and subsequent repairs, the machine is working for $N(\frac{1}{\lambda})$ units of time and is being repaired for $N(\frac{1}{\mu})$ units of time. The long run proportion of time the machine is working is then

$$\frac{N(\frac{1}{\lambda})}{N(\frac{1}{\lambda}) + N(\frac{1}{\mu})} = \frac{\mu}{\lambda + \mu}.$$

This value also turns out to be the steady-state probability of finding the system in state 0, with the machine working.



7.9.3 SPECIAL QUEUEING SYSTEMS

This section summarizes analytical results about special types of single-station queues.

Notation:

- $\frac{1}{\lambda} =$ expected interarrival time;
- $\tilde{A}(\cdot) =$ Laplace transform of the interarrival-time density;
- $\frac{1}{\mu} =$ expected service time;
- $\tilde{B}(\cdot) =$ Laplace transform of the service-time density;
- $\sigma^2 =$ variance of the service time;
- $s =$ number of servers;
- $\rho = \frac{\lambda}{s\mu} =$ traffic intensity.

The probability generating function (§7.3.3) for the steady-state distribution $\{p_j\}$ of a queueing system is $\phi(z) = \sum_{j=0}^{\infty} p_j z^j$, $|z| < 1$.

The Laplace transform for the waiting-time distribution $f(w)$ of a queueing system is $\psi(s) = \int_0^\infty e^{-sw} f(w)\,dw$, $Re(s) > 0$.

Facts:

1. The $M/M/1$ queue is stable if $\rho < 1$. The following results hold when the queue is stable.

$$\begin{aligned} p_j &= (1-\rho)\rho^j = \pi_j = \pi_j^* \\ L &= \tfrac{\rho}{1-\rho} \\ W &= \tfrac{1}{\mu-\lambda}. \end{aligned}$$

2. The $M/M/1/K$ queue is always stable. Assume $\rho \neq 1$.

$$\begin{aligned} p_j &= \tfrac{1-\rho}{1-\rho^{K+1}}\rho^j, \quad 0 \leq j \leq K \\ \pi_j^* &= \tfrac{p_j}{1-p_K} = \pi_j, \quad 0 \leq j \leq K-1 \\ L &= \tfrac{\rho}{1-\rho}(\tfrac{1-\rho^K}{1-\rho^{K+1}} - Kp_K) \\ W &= \tfrac{1}{\mu-\lambda}(\tfrac{1-\rho^K}{1-\rho^{K+1}} - Kp_K). \end{aligned}$$

If $\rho = 1$, the above formulas reduce to

$$\begin{aligned} p_j &= \tfrac{1}{K+1}\,, \quad 0 \leq j \leq K \\ \pi_j^* &= \pi_j = \tfrac{1}{K}\,, \quad 0 \leq j \leq K-1 \\ L &= \tfrac{K}{2} \\ W &= \tfrac{K}{2\mu}\,. \end{aligned}$$

3. The $M/M/s$ queue is stable if $\rho < 1$. The following results hold when the queue is stable.

$$\begin{aligned} p_0 &= \left(\sum_{n=0}^{s-1} \tfrac{(s\rho)^n}{n!} + \tfrac{s^s}{s!}\tfrac{\rho^s}{1-\rho}\right)^{-1} \\ p_j &= \begin{cases} \tfrac{(s\rho)^j}{j!}p_0, & 0 \leq j < s \\ \tfrac{s^s}{s!}\rho^j p_0, & j \geq s \end{cases} \\ \pi_j &= \pi_j^* = p_j, \quad j \geq 0 \\ L &= \rho(s + \tfrac{p_s}{(1-\rho)^2}) \\ W &= \tfrac{1}{s\mu}(s + \tfrac{p_s}{(1-\rho)^2}) \\ E(\text{number of busy servers}) &= \rho. \end{aligned}$$

4. The $M/M/\infty$ queue is always stable.

$$\begin{aligned} p_j &= e^{-(\lambda/\mu)}\tfrac{(\lambda/\mu)^j}{j!}, \quad j \geq 0 \\ \pi_j &= \pi_j^* = p_j, \quad j \geq 0 \\ L &= \tfrac{\lambda}{\mu} \\ W &= \tfrac{1}{\mu}. \end{aligned}$$

5. The $M/G/1$ queue is stable if $\rho < 1$. The following results hold when the queue is stable.

$$\begin{aligned} p_0 &= 1 - \rho, \\ \pi_j &= \pi_j^* = p_j \\ \phi(z) &= (1-\rho)\tfrac{(1-z)\tilde{B}(\lambda(1-z))}{\tilde{B}(\lambda(1-z))-z} \\ \psi(s) &= (1-\rho)\tfrac{s\tilde{B}(s)}{s-\lambda(1-\tilde{B}(s))} \\ L &= \rho + \tfrac{\rho^2+\lambda^2\sigma^2}{2(1-\rho)} \\ W &= \tfrac{1}{\mu} + \tfrac{\lambda((1/\mu)^2+\sigma^2)}{2(1-\rho)}. \end{aligned}$$

The last four equations are the various forms of the *Pollaczek-Khintchine formula*. No closed form results are available for $M/G/c$ queues for $2 \leq c < \infty$.

6. The $M/G/c/c$ queue, also called a *loss system*, is always stable. The main result is

$$p_j = \frac{\rho^j/j!}{\sum\limits_{n=0}^{c} \rho^n/n!}, \qquad 0 \le j \le c.$$

7. The $M/G/\infty$ queue is always stable.

$$\begin{aligned} p_j &= e^{-(\lambda/\mu)} \tfrac{(\lambda/\mu)^j}{j!}, \quad j \ge 0 \\ \pi_j &= \pi_j^* = p_j, \quad j \ge 0 \\ L &= \tfrac{\lambda}{\mu} \\ W &= \tfrac{1}{\mu}. \end{aligned}$$

8. The $G/M/1$ queue is stable if $\rho < 1$. When the queue is stable there is a unique solution $\alpha \in (0,1)$ to $\alpha = \tilde{A}(\mu(1-\alpha))$. The following results hold when the queue is stable.

$$\begin{aligned} \pi_j^* &= (1-\alpha)\alpha^j = \pi_j, \quad j \ge 0 \\ p_0 &= 1-\rho \\ p_j &= \rho\pi_{j-1}^*, \quad j \ge 1 \\ L &= \tfrac{\rho}{1-\alpha} \\ W &= \tfrac{1}{\mu}\tfrac{1}{(1-\alpha)}. \end{aligned}$$

The $G/M/c$ queue can be analytically solved, but the results are complicated.

9. The $G/M/\infty$ queue is always stable.

$$\begin{aligned} L &= \tfrac{\lambda}{\mu} \\ \text{variance of number in system } &= \tfrac{\lambda}{\mu}(1-\tfrac{\lambda}{\mu}) + \tfrac{\lambda/\mu}{2}\tfrac{\tilde{A}(\mu)}{1-\tilde{A}(\mu)}. \end{aligned}$$

Examples:

1. At a drop-in legal clinic, the lawyer sees four clients during a typical (eight hour) day. Each client's case requires on average 1.5 hours of the lawyer's time. If arrivals are Poisson and service times are exponentially distributed, then this is an $M/M/1$ queue with $\lambda = \frac{4}{8} = \frac{1}{2}$ customers per hour and $\frac{1}{\mu} = \frac{3}{2}$. Here $\rho = \frac{\lambda}{\mu} = \frac{3}{4} < 1$, so the queue is stable. Using Fact 1, $p_0 = 1 - \rho = \frac{1}{4}$, so there is probability $\frac{1}{4}$ that the lawyer is idle. The expected number of clients in the clinic is $L = \frac{\rho}{1-\rho} = 3$ and the average wait of a client is $W = \frac{1}{\mu-\lambda} = 6$ hours.

2. Customers arrive at a service station according to a Poisson process with rate 10 per hour. The manager has two options: (a) employ a single fast server who can service a customer in five minutes on average, or (b) employ two slow servers each taking ten minutes on average to serve a customer. Assume that the service times are exponential. Which option should the manager implement to minimize the expected waiting time in steady state?

Under (a) the system is an $M/M/1$ queue with $\lambda = 10$, $\mu = 12$. Since $\rho = \frac{10}{12} < 1$, the system is stable. By Fact 1, $W = \frac{1}{12-10} = 0.5$ hours. Under (b) the system is an $M/M/2$ queue with $\lambda = 10$ and $\mu = 6$. The system is stable since $\rho = \frac{10}{2\cdot 6} < 1$. From Fact 3, $p_0 = \frac{1}{11}$, $p_2 = \frac{25}{198}$, and $W = \frac{6}{11} = 0.55$ hours. Thus option (a) is better. In general, it is better to employ a few fast servers than many slow servers with the same overall service capacity.

3. A system manager has the option of using one of three possible servers in a single-server system. The service times under the first server are exponential with mean of six minutes. Under the second server they are uniformly distributed over $[4, 8]$ minutes. Under the third they are constant, equal to six minutes. The customers arrive according to a Poisson process with rate 8 per hour. Which server should be chosen to minimize the expected waiting time in steady state?

The mean service time is six minutes; i.e., $\mu = 10$ per hour, for all three servers. However, the variances σ^2 are different. This $M/G/1$ system is stable under all three servers since $\rho = \frac{8}{10} < 1$. For server one, $\sigma^2 = 0.01$ (hours)^2 and $W = 0.5$ hours. For the second server, $\sigma^2 = \frac{1}{2700} = 0.000370$ (hours)^2 and $W = \frac{83}{270} = 0.31$ hours. For the third server, $\sigma^2 = 0.0$ (hours)^2 and $W = \frac{3}{10} = 0.3$ hours. Thus, it is best to use the server with constant service times. In general, reducing the variance of the service times has a beneficial effect on the system.

4. A small business wants to install a telephone system with multiple lines, though without any capacity for call queueing. This is to be done to ensure that 95% of the calls made to the business get answered. Suppose that the arrival process is Poisson with $\lambda = 10$ calls per hour, and that the average call lasts five minutes. This is an $M/G/c/c$ loss system (Fact 6), and it is necessary to find the smallest value of c such that $p_c \leq 0.05$. Using Fact 6 with $\rho = \frac{10}{12} = \frac{5}{6}$ and $c = 1$ gives $p_1 = \frac{\rho}{1+\rho} = 0.45$. Similar calculations give $p_2 = 0.16$ for $c = 2$ and $p_3 = 0.042$ for $c = 3$. Consequently, three lines are needed to ensure the stipulated grade-of-service requirement.

7.10 SIMULATION

Simulation is a technique for numerically estimating the performance of a complex stochastic system when analytic solution is not feasible. This section discusses both *discrete-event* and *Monte Carlo* simulation. In discrete-event simulation models, the passage of time plays a key role, as changes to the state of the system occur only at certain points in simulated time. For example, queueing and inventory systems can be studied by discrete-event simulation models. Monte Carlo simulation models do not, however, require the passage of time. Such models are useful in estimating eigenvalues, estimating π, and estimating the quantiles of a mathematically intractable test statistic in hypothesis testing. Simulation has been described [BrFoSc87] as "driving a model of a system with suitable inputs and observing the corresponding outputs." Accordingly, the following three subsections discuss input modeling, output analysis, and simulation programming languages.

7.10.1 INPUT MODELING

This subsection addresses three key issues in constructing a simulation model:

- determining a source of randomness to drive the probabilistic aspects of the model;
- input model selection to determine the appropriate probabilistic models to drive the simulation;

- random variate generation algorithms that transform random numbers to random variates.

Definitions:

Random numbers are real numbers generated uniformly over the interval $(0, 1)$.

A ***random number generator*** is any mechanism or algorithm for generating random numbers.

Pseudo-random numbers are values generated deterministically, but that appear to behave like independent and identically distributed random numbers.

Let m be a large prime integer. A ***purely multiplicative linear congruential generator*** (§4.3.1) produces a stream of pseudo-random numbers $\{\frac{x_i}{m} \mid i \geq 1\}$ based on the recursive relationship $x_{i+1} = ax_i \pmod{m}$, where a is an integer ***multiplier*** between 1 and $m-1$, and x_0 is an integer ***seed*** between 1 and $m-1$.

An ***input model*** characterizes the stochastic elements of a discrete-event simulation model.

A ***trace-driven*** input model generates a process that is identical to the collected data values without relying on a parametric model.

A ***random variate*** is a realization of a random variable.

Facts:

1. Stochastic simulations typically derive their source of randomness from random numbers. That is, inputs to the simulated system need to be generated according to a specified probability model, a task that can be accomplished by suitably transforming (uniform) random numbers.

2. Desirable properties for random number generators include: uniformity, independence, speed, minimal memory requirements, ease of implementation, portability across various computer systems, reproducibility, and multiple stream capability.

3. Although numerous methods have been proposed for generating random numbers, multiplicative linear congruential generators are typically used to produce a stream of pseudo-random numbers.

4. Due to the prevalence of 32-bit computer architecture, m is often chosen to be $2^{31}-1$, which is prime.

5. A *full period* generator, which cycles through all $m-1$ possible x_i values prior to repeating, is obtained by selecting a to be a primitive root modulo m. (See §4.7.1.)

6. Software for pseudo-random number generators can be found at

- `http://random.mat.sbg.ac.at/software`
- `http://www.taygeta.com/random.html`

7. Additional information on the theoretical and empirical performance of a variety of pseudo-random number generators is available at

- `http://random.mat.sbg.ac.at/generators`
- `http://random.mat.sbg.ac.at/tests`

8. If the multiplier a is chosen so that it is "modulus-compatible" with m, then potential overflow can be averted for large values of m. Two values of a that are often used with $m = 2^{31} - 1$ are $a = 7^5 = 16{,}807$ and $a = 48{,}271$ [PaMi88].

9. More detail concerning random number generation is given by [LE94] and [LE12].

10. Successful input modeling for a discrete-event simulation requires a close match between the input model and the true underlying probabilistic mechanism associated with the system.

11. One of the first steps in determining an appropriate input model for an element of a discrete-event simulation is to assess whether the observations are independent and identically distributed.

12. An input model can be specified in several ways: e.g., using a cumulative distribution function, joint probability density function, hazard function, intensity function, or variate-generation algorithm.

13. Potential input models for simulation are described in references [BaNe03], [FoEtal11], [JoKoBa94] and at

- `http://www.math.wm.edu/~leemis/chart/UDR/UDR.html`

14. Many input models rely on parametric probabilistic models such as the binomial, normal, and Weibull distributions. Maximum likelihood is typically used to estimate parameters of these models.

15. Bézier curves [FlWi93] offer a unique combination of the parametric and nonparametric approaches. After an initial distribution is fitted to the dataset, the modeler decides whether differences between the empirical and fitted models represent sampling variability (chance variation) or an aspect of the distribution that should be included in the input model.

16. Multivariate distributions (e.g., the multivariate normal distribution with mean μ and variance-covariance matrix Σ) are considered by [Jo87].

17. Once an input model has been chosen, random variate generation algorithms are used to transform random numbers to random variates from the input model.

18. Devroye [De86] gives algorithms for converting random numbers to random variates associated with input models chosen to drive the simulation.

19. Techniques commonly used for generating random variates from univariate probability distributions are: inverse transformation, composition, acceptance/rejection, and special properties.

20. Algorithm 1, which shows the inversion method for generating a univariate random variate X, is based on the probability integral transformation. It is assumed that the cumulative distribution function $F(x)$ for the input model of interest has the inverse $F^{-1}(U)$.

```
Algorithm 1: Inverse transformation method.
  input: cumulative distribution function $F$
  output: a random variate $X$ from this distribution
  generate $U$ uniformly over $(0,1)$
  $X := F^{-1}(U)$
```

21. Other topics in random variate generation include table methods, generating from multivariate distributions, random sampling, estimating integrals, and generating processes correlated in time.

Examples:

1. Suppose that a sequence of arrival times (e.g., of customers at a bank) is collected over a 24-hour time period. A *trace-driven* input model for the arrival process is generated by having arrivals occur at the same times as the observed values.

2. Let $t_1, t_2, \ldots, t_n$ be the arrival times to a queue collected on the time interval $(0, c]$. If the times between arrivals are independent and identically distributed, a parametric or nonparametric model can be fitted to the data. In the former case, parameters are often estimated by maximizing the *likelihood function* [La15]

$$L(\boldsymbol{\theta}) = \prod_{i=1}^{n} f(x_i, \boldsymbol{\theta}),$$

where $x_i = t_i - t_{i-1}$ for $i = 1, 2, \ldots, n$, $t_0 \equiv 0$, $\boldsymbol{\theta} = (\theta_1, \theta_2, \ldots, \theta_p)$ is a vector of unknown parameters, and $f(x_i, \boldsymbol{\theta})$ is the probability density function of the interarrival times.

3. If the interarrival times to a queue (as in Example 2) are not independent and identically distributed, then a nonstationary point process might be considered, such as a nonhomogeneous Poisson process, where the arrival rate $\lambda(t; \theta)$ varies over time. One parametric model is the *power law* process, with intensity function $\lambda(t; \lambda, \kappa) = \lambda^\kappa \kappa t^{\kappa - 1}$ for $t > 0$, where λ and κ are positive parameters. The likelihood function for the single realization on $(0, c]$ is $L(\lambda, \kappa) = \left(\prod_{i=1}^{n} \lambda(t_i; \lambda, \kappa)\right) \exp\left(- \int_0^c \lambda(t; \lambda, \kappa)\, dt\right)$. Maximum likelihood estimators can be determined by maximizing $L(\lambda, \kappa)$ or its logarithm with respect to λ and κ. Confidence regions for the unknown parameters can be found by using asymptotic properties of the likelihood ratio statistic or the observed *information matrix* [La15]. As with all statistical modeling, goodness-of-fit tests should be performed in order to assess the model adequacy.

4. *Weibull distribution*: The *Weibull distribution* has cumulative distribution function

$$F(x) = 1 - e^{-(\lambda x)^\kappa} \text{ for } x > 0.$$

The inverse cumulative distribution function is $F^{-1}(y) = \dfrac{[-\ln(1-y)]^{1/\kappa}}{\lambda}$ for $0 < y < 1$. Algorithm 1 can be used to generate a Weibull variate according to

$$X := \frac{[-\ln(1-U)]^{1/\kappa}}{\lambda}.$$

5. $M/M/1$ *queue*: To simulate the operation of a single-server queue (§7.9.1) having Poisson arrivals at arrival rate λ and exponential service times with service rate μ, exponentially generated variates are needed for the interarrival times $\{I_n\}$ and the service times $\{S_n\}$. These are available as a special case of the Weibull distribution (Example 4) with $\kappa = 1$ and can be generated using $I_n = \dfrac{-\ln(1-U_n)}{\lambda}$ and $S_n = \dfrac{-\ln(1-V_n)}{\mu}$, with the $\{U_n\}$, $\{V_n\}$ generated uniformly over $(0, 1)$.

A concrete example is provided in the following table, which shows one simulated run of an $M/M/1$ queue with $\lambda = 0.5$ and $\mu = 0.7$. The table shows, in successive columns, the following values for each customer n: the interarrival time I_n, the arrival time A_n, the service time S_n, the beginning time of service B_n, the departure time D_n, and the sojourn time $W_n = D_n - A_n$. Notice that customers $1, 4, 7, 8, 9$ are served immediately and incur no waiting time in the queue.

customer	I_n	A_n	S_n	B_n	D_n	W_n
1	5.44	5.44	0.78	5.44	6.22	0.78
2	0.61	6.05	2.77	6.22	8.99	2.94
3	0.35	6.40	0.96	8.99	9.95	3.55
4	4.12	10.52	2.42	10.52	12.94	2.42
5	0.54	11.06	0.88	12.94	13.82	2.76
6	2.07	13.13	0.87	13.82	14.69	1.56
7	6.82	19.95	0.86	19.95	20.81	0.86
8	2.19	22.14	0.76	22.14	22.90	0.76
9	4.09	26.23	3.31	26.23	29.54	3.31
10	0.02	26.25	0.01	29.54	29.55	3.30

7.10.2 OUTPUT ANALYSIS

Once a verified and validated simulation model has been developed, a modeler typically wants to estimate measures of performance associated with outputs of the model. Although there are often several performance measures of interest, a single measure of performance θ (e.g., the mean waiting time in a queue) is studied here. This subsection discusses using point estimation to compute an estimate for θ, determining a confidence interval for the point estimate, and applying variance reduction techniques to obtain more precise point estimates.

Definitions:

Suppose $\{Y_i\}$ is the ***output stochastic process***. If the output stochastic process consists of independent observations obtained from a population with cumulative distribution function F_Y, the ***pth quantile*** of F_Y is the value y_p such that $F_Y(y_p) = p$. The ***median*** of F_Y corresponds to $p = 0.5$.

The ***sample mean*** of the observations $Y_1, Y_2, \ldots, Y_n$ is given by $\overline{Y} = \frac{1}{n}\sum\limits_{i=1}^{n} Y_i$.

If the values $Y_1, Y_2, \ldots, Y_n$ are rearranged so that $Y_{(1)} \le Y_{(2)} \le \cdots \le Y_{(n)}$ then $Y_{(i)}$ is the ith ***order statistic***.

The ***mean*** μ_Y of the process is the asymptotic mean of the output process $\{Y_i\}$.

The ***variance*** σ_Y^2 of the process is the asymptotic mean of the output process $\{(Y_i - \overline{Y})^2\}$.

The ***probability*** $Pr(A)$ of event A is the asymptotic mean of the output process $\{I(A)\}$, where I is the 0-1 indicator function for event A.

The output process $Y_1, Y_2, \ldots$ is ***covariance stationary*** if, for finite mean μ and finite variance $\sigma^2 > 0$, $E(Y_i) = \mu$, $i = 1, 2, \ldots$, $\mathrm{Var}(Y_i) = \sigma^2$, $i = 1, 2, \ldots$, and $\mathrm{Cov}(Y_i, Y_{i+j})$ is independent of i, for $j = 1, 2, \ldots$.

Variance reduction techniques are strategies for obtaining greater precision for a fixed amount of sampling.

Time-persistent statistics are often calculated in discrete-event simulations. These statistics fundamentally differ from statistics that are based on observations $Y_1, Y_2, \ldots, Y_n$. Time-persistent statistics account for the value of a performance measure of interest (for example, the number of customers in a waiting line) and also the length of time that the value was held.

Facts:

1. The three most common measures of performance to be estimated in Monte Carlo simulation and discrete-event simulation are means, probabilities, and quantiles.

2. Point estimates for μ_Y, σ_Y^2, $Pr(A)$ are typically given by the associated sample statistics, that is, the sample mean, the sample variance, and the fraction of occurrences of the event A.

3. A simple estimator of $y_p = F_Y^{-1}(p)$ is $Y_{(s)}$, where $s = \lfloor p(n+1) \rfloor$. This estimator can be improved (with respect to bias) by estimating $F_Y^{-1}(p)$ with the linear combination $(1-\alpha)Y_{(s)} + \alpha Y_{(s+1)}$, where $\alpha = p(n+1) - \lfloor p(n+1) \rfloor$.

4. Sample means, variances, and quantiles can also be estimated for time-persistent statistics [Ne13].

5. *Replication*: This is one of the simplest methods of interval estimation, in which several runs of a simulation model are used. Classical confidence intervals based on the central limit theorem for the measures of interest are often applied to the output.

6. The presence of autocorrelation among observations (e.g., the waiting times of adjacent customers in a queue) significantly complicates the statistical analysis of simulation output from a single run.

7. To analyze a single simulation run with autocorrelation present, techniques have been developed for determining interval estimates whose actual coverage is close to the stated coverage. For many of these techniques, the output is assumed to be covariance stationary. These techniques include batch means, overlapping batch means, standardized time series, regeneration, spectral analysis, and autoregression [La15].

8. *Common random numbers*: This is a variance reduction technique in which two or more alternative system configurations are analyzed using the same set of random numbers for particular purposes (e.g., generating service times). Using common random numbers ensures that the output differences are due to the configurations rather than the sampling variability in the random numbers.

9. *Antithetic variates*: This is a second variance reduction technique, applicable to the analysis of a single system. If the random numbers $\{U_i\}$ are used for a particular purpose in one simulation run, then using $\{1 - U_i\}$ in a second run typically induces a negative correlation between the outputs of the two runs. Thus, the average of the output measures from the two runs will have a reduced variance.

10. There are a variety of variance reduction techniques. See Wilson [Wi84] for a detailed discussion.

11. Other topics in output analysis include initialization bias detection, ranking and selection, comparing alternative system designs, experimental design, and optimization.

Examples:

1. *Confidence intervals for expected waiting times*: Let $X_1, X_2, \ldots, X_n$ be the averages of the waiting times of customers in a single-server queue from n independent replications of a discrete-event simulation model. A $100(1-\alpha)\%$ confidence interval for μ, the steady-state mean waiting time, is

$$\overline{X} - t_{\alpha/2,n-1}\, \tfrac{s}{\sqrt{n}} < \mu < \overline{X} + t_{\alpha/2,n-1}\, \tfrac{s}{\sqrt{n}}\ ,$$

where $\overline{X}$ is the sample mean, s is the sample standard deviation, and $t_{\alpha/2,n-1}$ is the $\frac{1}{1-\alpha/2}$ quartile of the t distribution with $n-1$ degrees of freedom. Each replication must be “warmed up” to avoid initialization bias. The asymptotic normality of $X_1, X_2, \ldots, X_n$ is assured by the central limit theorem and independence is based on the use of independent random number streams.

2. *$M/M/1$ queue*: The simulation in Example 5 of §7.10.1 was executed so that the first 200 customer wait times were collected. The measure of performance θ for the system is the steady-state expected customer wait time. The initial conditions for each replication are an empty system and an idle server. The stopping time for each replication is when the 200th customer departs. Running this simulation experiment for $n = 100$ replications gave $\overline{X} = 4.72$ and for $n = 500$ replications gave $\overline{X} = 4.76$. For this simple queueing system, the steady-state analytical solution is $W = \frac{1}{\mu-\lambda} = 5.0$ (§7.9.3, Fact 1). These averages are biased low because the early waiting times have a lower expected value than the subsequent waiting times as a result of the initial conditions. To improve these point estimates, the system was permitted to warm up for the first 100 customers and the average waiting time was then calculated for the last 100 customers. In this case, rerunning the simulation gave the improved estimates $\overline{X} = 5.20$ for $n = 100$ and $\overline{X} = 4.93$ for $n = 500$.

3. *Common random numbers*: Law [La15, pp. 596–597] compares the $M/M/1$ and the $M/M/2$ queueing models with a utilization of $\rho = 0.9$ using the waiting times in the queue of the first 100 customers. With $n = 100$ independent replications of each system, the two models are compared in four ways:

- independent runs (I);
- arrival streams using common random numbers (A);
- service times using common random numbers (S);
- arrival streams and service times using common random numbers (A & S).

Common random numbers is a variance reduction technique that feeds identical interarrival and/or service times into the two different queueing models to increase the likelihood that observed differences in the waiting times are due to the system configurations ($M/M/1$ versus $M/M/2$) rather than sampling error. The mean half-widths of the confidence intervals ($\alpha = 0.10$) reported for this example are $0.70(I), 0.49(A), 0.49(S)$, and $0.04(A \,\&\, S)$.

7.10.3 SIMULATION LANGUAGES

This subsection considers the history and features of simulation programming languages developed over the years.

Facts:

1. The use of a general-purpose simulation programming language (SPL) expedites model development, input modeling, output analysis, and animation. In addition, SPLs have accelerated the use of simulation as an analysis tool by bringing down the cost of developing a simulation model.

2. In a history of the development of SPLs from 1955 to 1986, Nance [Na93] defines six requirements that an SPL must meet:

- random number generation;
- random variate generation;
- list processing capabilities so that objects can be created, altered, and deleted;
- statistical analysis routines;

- summary report generators;
- a timing executive or event calendar to model the passage of time.

3. SPLs may take the form of

- a set of subprograms in a general purpose language (GPL) such as Fortran or C that can be called to meet these six requirements;
- a preprocessor that converts statements or symbols to lines of code in a GPL;
- a conventional programming language.

4. The following table shows a division of the historical record into five distinct periods, including the names of several languages that came into existence in each period.

period	*characteristics*	*languages*
1955–1960	period of search	GSP
1961–1965	the advent	CLP, CSL, DYNAMO, GASP, GPSS, MILITRAN, OPS, QUIKSCRIPT, SIMSCRIPT, SIMULA, SOL
1966–1970	formative period	AS, BOSS, Q-GERT, SLANG, SPL
1971–1978	expansion period	DRAFT, HOCUS, PBQ, SIMPL
1979–1986	consolidation and regeneration	INS, SIMAN, SLAM

5. The General Purpose System Simulator (GPSS) was first developed on various IBM computers in the early 1960s. Algol-based SIMULA was also developed in the 1960s and had features that were ahead of its time. These included abstract data types, inheritance, the co-routine concept, and quasi-parallel execution.

6. SIMSCRIPT was developed by the RAND Corporation with the purpose of decreasing model and program development times. SIMSCRIPT models are described in terms of entities, attributes, and sets. The syntax and program organization were influenced by Fortran.

7. The Control and Simulation Language (CSL) takes an “activity scanning” approach to language design, where the activity is the basic descriptive unit.

8. The General Activity Simulation Program (GASP), in common with several other languages, used flow-chart symbols to bridge the gap between personnel unfamiliar with programming and programmers unfamiliar with the application area. Although originally written in Algol, GASP provided Fortran subroutines for list-processing capabilities (e.g., queue insertion).

9. GASP was a forerunner to both the Simulation Language for Alternative Modeling (SLAM) and SIMulation ANalysis (SIMAN) languages.

10. SLAM was the first language to include three modeling perspectives in one language: network (process orientation), discrete-event, and continuous (state variables).

11. SIMAN was the first major SPL executable on an IBM PC.

12. Simulation software has mushroomed, with numerous packages and languages available both for general purpose and application-specific simulations. Special purpose and integrated packages are widespread and available on desktop computers. The 2015 survey [Sw15] compares 55 products, having a wide range of features and capabilities.

13. A recent trend has been the addition of animation to intelligently view simulation output. Several web-based simulation tools can be found at

- `http://www.dcs.ed.ac.uk/home/hase/simjava/applets/index.html`
- `http://www.vissim.com`
- `http://www.anylogic.com`
- `http://www.um.es/fem/EjsWiki/index.php/Main/WhatIsEJS`

14. Software for carrying out Monte Carlo simulation can be found at the site

- `http://random.mat.sbg.ac.at/software`

15. A site that writes code for random variate generation for various probability distributions can be found at

- `http://statistik.wu-wien.ac.at/projects/anuran/index.html`

16. Winter Simulation Conference proceeding papers on simulation languages, modeling, analysis, applications, etc. are available at

7.11 THE PROBABILISTIC METHOD

The Probabilistic Method is a powerful technique for proving the existence of combinatorial structures with certain desired properties. This method seems ubiquitous because it provides a technique to deal with the "local-global" problem. More specifically, when one is confronted with the task of constructing a finite set structure that satisfies a certain combinatorial condition at every element, the total number of choices often grows exponentially, so it is very difficult to decide which choices are good. The probabilistic paradigm provides what one may call conditions for building a global patch from all the local data. The basic premise is the following: Define a suitable probability space and then prove that the probability of making no "bad choice" is positive. In particular, its power is most visible when it is used to prove deterministic statements. We describe here briefly some of the main aspects of the probabilistic method. There are numerous books, monographs, and lecture notes on the subject including [AlSp08], [MoRe00], [Sp87].

7.11.1 THE BASIC METHOD

Definitions:

Suppose (Ω, Pr) is a probability on a finite set Ω and let $X : \Omega \to \mathcal{R}$ be a random variable on Ω. The ***expectation*** of X is given by $E(X) = \sum_{\omega\in\Omega} X(\omega)\, Pr(\omega)$.

The ***Ramsey number*** $R(k, k)$ is the least integer N such that for every two-coloring of the edges of the complete graph K_n with $n \geq N$, there is a monochrome complete subgraph on k vertices.

A hypergraph is said to be ***n-uniform*** if each edge size is n. We say that a hypergraph $\mathcal{H} = (\mathcal{V}, \mathcal{E})$ has ***Property B*** (after Felix Bernstein, 1878–1956) if each vertex in $\mathcal{V}$ can be assigned one of two colors so that no edge $E \in \mathcal{E}$ is monochromatic, i.e., for no edge $E \in \mathcal{E}$ is it the case that every vertex of E has been assigned the same color.

A set $B \subset \mathcal{R}$ is called ***sum-free*** if the sum of any two elements in B does not lie in B.

The ***girth*** of a graph is the size of a smallest cycle in the graph. If the graph is acyclic then its girth is defined to be ∞.

Facts:

1. Suppose (Ω, Pr) is a probability on the finite set Ω and $X, Y : \Omega \to \mathcal{R}$ are random variables on Ω. Then

$$\begin{aligned} E(X+Y) &= E(X) + E(Y), \\ E(\lambda X) &= \lambda E(X), \text{ for real } \lambda. \end{aligned}$$

This is expressed by saying that expectation is linear.

2. If X is a random variable defined on a probability space (Ω, Pr), then $Pr(X \geq E(X)) > 0$ and $Pr(X \leq E(X)) > 0$. In particular, with positive probability, there exist $\omega, \omega' \in \Omega$ such that $X(\omega) \geq E(X)$ and $X(\omega') \leq E(\omega')$.

3. *Markov's inequality*: If $X : \Omega \to \mathcal{R}^+$ is a nonnegative valued random variable, then for any $a > 0$

$$Pr(X > a) \leq \tfrac{E(X)}{a}.$$

Examples:

We include several examples that illustrate how the method basically works. These examples span several areas of discrete mathematics, including additive combinatorics, extremal combinatorics, combinatorial geometry, and graph theory.

1. *Lower bound for $R(k,k)$*: We shall show that $R(k,k) > 2^{k/2}$ [Er47]. To do so, color each edge of K_n red or blue independently, and with equal probability. Then the probability that there exists a monochrome K_k under this coloring is at most $\binom{n}{k}2^{-\binom{k}{2}+1}$ since there are $\binom{n}{k}$ distinct k subsets of $\{1, 2, \ldots, n\}$ and for each fixed k subset, the probability that all the edges incident with those vertices bear the same color is $2^{-\binom{k}{2}+1}$. Now, a routine calculation shows that for $n = 2^{k/2}$ this expression is less than one under a random two-coloring. In particular, with positive probability, no k-subset of the vertex set induces a monochromatic K_k.

2. *Colored hats and a guessing game*: There are n friends standing in a circle so that everyone can see everybody else. On each person's head a randomly chosen hat—either black or white—is placed. After they have had a look at each other, they must simultaneously shout, "my hat is black","my hat is white", or "I don't know the color of my hat". The friends may make any strategy prior to the placement of the hats but subsequent to that, they are not allowed to communicate in any manner. They are awarded a grand prize if at least one person gets the color of her hat correct, and *no one gets her hat color wrong.* In the latter case, they are all punished. The friends need to devise a strategy that increases the probability of their getting the reward.

One strategy for the beating the 50-50 odds is the following. Denoting white and black by 1 and 0 respectively, any configuration of hats on their heads is a point in $\{0,1\}^n$. Suppose there exists a set $L \subset \{0,1\}^n$ such that for every element $(x_1, x_2, \ldots, x_n) \in W = \{0,1\}^n \backslash L$ there is an element $(y_1, y_2, \ldots, y_n) \in L$ such that the set $\{i \mid x_i \neq y_i\}$ has size 1. In this case we say that the set L is *desirable*. Here is a strategy for the n friends: Person i knows x_j for all $j \neq i$, so if there is a unique value of x_i so that $(x_1, x_2, \ldots, x_n) \in W$ then person i declares that her hat color is x_i. It then follows that the probability of getting the award by following this strategy is $|W|/2^n$. Thus to maximize this probability, they need a "small" desirable set L. This can be obtained by making a random choice. Pick a set X by choosing each element of $\{0,1\}^n$ independently with probability p (to be determined).

If Y is the set of elements which differ from the chosen elements in at least two coordinates then $E(|Y|) = 2^n(1-p)^{n+1}$, so the set $L = X \cup Y$ satisfies the required condition. Furthermore, by linearity of expectation $E(|L|) = E(|X| + |Y|) = 2^n(p + (1-p)^{n+1})$. Minimizing this over $p \in [0,1]$ we get $E(|L|) \le 2^n O\left(\frac{\log n}{n}\right)$. In particular, the n friends can achieve a success rate of $1 - O\left(\frac{\log n}{n}\right)$. One can also prove similar results when the friends are assigned hats that may take any one of q different colors, for any $q \ge 2$. See [Al08] for other related results.

3. *Property B in uniform hypergraphs*: Denote by $m(n)$ the least number of edges in an n-uniform hypergraph which does *not* have Property B. Then we have [Er63], [Er64]

$$2^{n-1} \le m(n) \le O(n^2 2^n).$$

For the lower bound, we need to show that any n-uniform hypergraph with fewer than 2^{n-1} edges is 2-colorable. To see that, given such a hypergraph $\mathcal{H}$, randomly and uniformly and independently color each vertex red or blue. Then if N denotes the number of monochrome edges, then $E(N) = \sum_{E \in \mathcal{E}} Pr(E \text{ is monochrome}) < 1$ since the probability that any given edge is monochrome is precisely $1/2^{n-1}$. Thus there is some choice of vertex coloring such that no edge is monochrome.

For the upper bound, we pick a random hypergraph as follows. Let V be the set $\{1, 2, \ldots, v\}$ and choose m edges from the set of all n-subsets of V, independently at random: specifically, pick an edge E with probability $1/\binom{v}{n}$, and repeat this process over m rounds. Here v, m will be chosen later. Now, fix a partition Π of V into two parts of sizes a, b. Then the probability that an edge that is not monochrome for Π is selected for $\mathcal{H}$ equals

$$\frac{\binom{a}{n} + \binom{b}{n}}{\binom{v}{n}} \ge \frac{2\binom{v/2}{n}}{\binom{v}{n}},$$

so the probability that there exists a partition Π such that the corresponding coloring for $\mathcal{H}$ has no monochrome edges is at most

$$(\#\text{ of 2-colorings of } V) \cdot (1-P)^m \le 2^v e^{-Pm},$$

where P denotes the quantity $\frac{2\binom{v/2}{n}}{\binom{v}{n}}$. Some calculation and optimizing for m shows that for $v = n^2/2$ and n large enough we have $m \le \frac{n^2}{2} \ln(2) \cdot 2^{n-1} \cdot e^{1+o(1)}$. It is conjectured that $m(n)/2^n = \Theta(n)$. The best known result is $m(n)/2^n = \Omega(\sqrt{\frac{n}{\log n}})$. [RaSr00]

4. *Sum-free subsets of a given set*: Given a set $B \subset \mathcal{N}$ of size n, how large a sum-free subset can it contain? We will show that B contains a sum-free subset of size greater than $|B|/3$. [Er65], [AlKl90]

Pick a prime p of the form $3k+2$ which is larger than twice the maximum absolute value of elements in B. By our choice of p, all of the elements in B are distinct mod p. Now, consider the sets $xB = \{xb \mid b \in B\}$ in $\mathcal{Z}/p\mathcal{Z}$, and let $N(x) = |[k+1, 2k+1] \cap xB|$. Now note in order to find a sum-free subset of B of the desired size, it suffices to find some $x \in \mathcal{Z}/p\mathcal{Z}$ such that $N(x) > n/3$ since the set $\{k+1, k+2, \ldots, 2k+1\}$ in $\mathcal{Z}/p\mathcal{Z}$ is sum-free. To find such an x, pick $x \in (\mathcal{Z}/p\mathcal{Z}) \setminus \{0\}$ uniformly at random. Then

$$E(N(x)) = \sum_{b \in B} Pr\left(x \cdot b \in [k+1, 2k+1]\right) = n \cdot \tfrac{k+1}{3k+1} > n/3.$$

This again implies that there exists some x such that $N(x) > n/3$ and that completes the proof.

Another way to state this result is as follows. The best constant c for which every set of integers of size n contains a sum-free subset of size at least cn is at least as large as $1/3$. It has been shown that in fact $1/3$ is the best possible constant [EbGrMa14].

Alterations:

Sometimes the probabilistic method may not produce the desired object itself but can prove the existence of an object which is very "close" to what is desired.

1. *Improvement on* $R(k,k)$: Color the edges of the complete graph K_n red or blue with equal probability, and independently for distinct edges. Then the expected number of monochrome copies of K_k is $m = \binom{n}{k}2^{-\binom{k}{2}+1}$. Thus there is a coloring of the edges in which there are at most m monochrome copies of K_k. Now, from each such monochrome copy, delete a vertex; then the resulting graph on $n-m$ vertices has no monochrome K_k. Thus we get $R(k,k) > n - \binom{n}{k}2^{-\binom{k}{2}+1}$. Optimizing this for n (for fixed k) we get $R(k,k) > (\frac{1}{e}+o(1))k2^{k/2}$.

2. *A conjecture of Danzer-Grünbaum in combinatorial geometry*: Ludwig Danzer and Branko Grünbaum [DaGr62] conjectured the following: "Any configuration of $2n$ points in $\mathcal{R}^n$ contains some three points that form a non-acute angle". In fact, they managed a proof of the same for dimensions $2,3$. Following [ErFu83], we give a proof that refutes this conjecture for all $n \geq 40$. To do so, we try to pick a subset of vertices of the n-dimensional hypercube, and try to avoid right angles. Since the vertices of the hypercube are in one to one correspondence with the set of subsets of $\{1,2\ldots,n\}$, we can denote the vertices picked instead by subsets of $\{1,2,\ldots,n\}$. Now pick each subset of $\{1,2,\ldots,n\}$ independently with probability p for some p to be determined. Let $X = \#\{\{P,Q,R\} \mid \angle PQR = \frac{\pi}{2}\}$. Suppose the sets P,Q,R form a right angle. If we denote by V_P the vector in $\mathcal{R}^n$ corresponding to the set (vertex) P of the cube, then $\langle V_P - V_Q, V_R - V_Q\rangle = 0$ where $\langle\cdot,\cdot\rangle$ is the usual dot product in $\mathcal{R}^n$. This implies that $\emptyset = \bar{P}\cap Q\cap\bar{R}$ and $\emptyset = P\cap\bar{Q}\cap R$. Therefore $\{P,Q,R\}$ is a right angle triple if and only if $P\cap R\subset Q\subset P\cup R$. Hence if the set of points picked is S, then $E(|S|) = 2^n p$ and it is not difficult to see that $E(|X|) = \frac{6^n p^3}{2}$. Now if we remove one of the sets from each triple of X that appear among the sets chosen in S then the resulting set S' has no right angles either, so there is a subset S' of expected size at least $2^n p - \frac{6^n p^3}{2}$ with no right angles. Optimizing for p, we get $E(|S'|) \geq \frac{1}{3}\sqrt{\frac{2}{3}}\left(\frac{2}{\sqrt{3}}\right)^n$, so there is a set of size $\Omega((\frac{2}{\sqrt{3}})^n)$ in the n-dimensional hypercube in which no three points form a right angle. For $n \geq 40$, this exceeds $2n$.

For more recent and better bounds (including deterministic constructions) for large sets with only acute angles, and other generalizations, see [Be06].

3. *Graphs with arbitrarily large girth and large chromatic number:* Given $k,g \geq 3$ there exist graphs G with $\chi(G) > k$ and girth greater than g. The sketch of the proof of this result, due to Erdős [Er59], is as follows. Take the vertex set $V = \{1,2,\ldots,n\}$ and for each pair i,j select the corresponding edge with probability $p = n^{-1+\theta}$ for some $0 < \theta < 1/g$, independently for each pair. By the choice of p it follows that the probability that this graph has an independent set of size greater than $O(n^{1-\theta}\log n)$ is $o(1)$. Also, if X denotes the number of cycles in G of size at most g then $E(X) = o(n)$, so with high probability (probability greater than $\frac{1}{2}$) $X < n/2$. Hence with positive probability there exists a graph for which the number of cycles of size at most g is less than $n/2$ *and* the size of maximum independent set in G is at most $O(n^{1-\theta}\log n)$. Fix such a graph and remove a vertex from each small cycle (i.e., a cycle of size at most g). The resulting graph has no small cycles, at least $n/2$ vertices, and $\chi(G) > \Omega\left(\frac{n^\theta}{\log n}\right)$.

7.11.2 DEPENDENT RANDOM CHOICE

For some instances of proving the existence of a combinatorial structure with certain desired properties, it is better to choose a different object randomly and then pick a relevant object associated with the randomly chosen object to be our desired object. Since we do not choose our actual objects of interest randomly but rather in some *dependent manner*, this method is referred to as the method of Dependent Random Choice.

Definitions:

For a graph H, $\boldsymbol{ex(n; H)}$ denotes the maximum number of edges in a graph on n vertices without a copy of H.

For a graph H, the ***Ramsey number*** $R(H)$ denotes the minimum number of vertices N such that every two coloring of the edges of K_N admits a monochrome copy of H.

The n-dimensional ***hypercube*** Q_n is the graph whose vertices are all the binary sequences of length n; two vertices are adjacent if and only if they differ in exactly one coordinate.

Examples:

1. Suppose H is bipartite with vertex partition $A \cup B$ and let $|A| = a$, $|B| = b$. In [AlKrSu03], the authors prove that if every vertex of B has degree at most r, then $ex(n; H) = O(n^{2-\frac{1}{r}})$. To see this, we shall try to embed each vertex of H into any graph G with $Cn^{2-1/r}$ edges for some absolute constant C. First we show that G contains a subset of vertices A_0 of size at least $a + b$ with the property that every r-subset of A_0 has at least $a+b$ common neighbors in G. To achieve this, pick a subset $T \subset V(G)$ over t rounds, at random (with repetition, and uniformly over each round). Consider the set of common neighbors of T which we denote by $N^*(T)$. If d denotes the average degree of the vertices of G, then

$$E(|N^*(T)|) = \textstyle\sum_{v \in V} Pr(v \in N^*(T)) = \sum_{v \in V} \left(\frac{d(v)}{n}\right)^t \geq \frac{d^t}{n^{t-1}}.$$

Let Y denote the number of r-subsets U of $N^*(T)$ such that U has fewer than $a + b$ common neighbors. If U is a subset of size r with fewer than $a + b$ neighbors, the event $U \subset N^*(T)$ occurs only if every element of T was picked from among the common neighbors of U, so $Pr(U \subset N^*(T)) \leq (\frac{a+b}{n})^t$, and hence by linearity of expectation, $E(Y) \leq \binom{n}{r}(\frac{a+b}{n})^t$. So, $E(|N^*(T)| - Y) \geq \frac{d^t}{n^{t-1}} - \binom{n}{r}(\frac{a+b}{n})^t$. Thus it follows that there exists a set $A_0 \subset N^*(T)$ of size $\geq \frac{d^t}{n^{t-1}} - \binom{n}{r}(\frac{a+b}{n})^t$ such that every r-subset of A_0 has at least $a+b$ common neighbors in G. Now since $V(H) = A \cup B$, we embed the vertices of A into A_0 arbitrarily. To embed the vertices of B, let $B = \{v_1, v_2, \ldots, v_b\}$ and suppose that we have already embedded $v_1, \ldots, v_{i-1}$ into A_0. Let W denote the set of neighbors of v_i in A (in the graph H). Since A has been embedded into A_0, this gives a set $U \subset V(G)$ of size at most r corresponding to the set of neighbors of v_i. But every U of size at most r has at least $a + b$ neighbors in G, of which at most $a + i - 1$ (with $i < b$) vertices are already assigned to some vertex of $A \cup B$. Hence, v_i can be embedded into A_0 as well. To complete the proof, some routine calculations show that for $C > \frac{1}{2}(a + \frac{(a+b)^r}{r!})^{\frac{1}{r}}$ we have $|A_0| \geq a + b$.

2. *The Ramsey number* $R(Q_n)$: Burr and Erdős [BuEr75] conjectured that $R(Q_n) = O(2^n)$. This conjecture is yet unsettled, but we show here (following [FoSu11]) that $R(Q_n) \leq 2^{3n}$. Set $N = 2^{3n}$ and consider the denser of the two colors that appear in a two coloring of the edges of K_N. There are at least $\frac{1}{2}\binom{N}{2}$ edges of this color, so the average degree of the graph G induced by edges of this color is at least $2^{-4/3}N$. Set $t = 3n/2, m = 2^n$ and $a = 2^{n-1}$. Then

$$\tfrac{d^t}{N^{t-1}} - \binom{N}{n}\left(\tfrac{m}{N}\right)^t \geq 2^{-4/3}N - N^{n-t}m^t/n! \geq 2^{n-1}.$$

As in the previous proof, it follows that the graph G contains a set U of size 2^{n-1} with the property that every n vertices of U have at least 2^n common neighbors. Since Q_n is an n-regular bipartite graph with parts of size 2^{n-1}, it follows that G contains Q_n.

3. For additional examples, see the survey paper [FoSu11].

7.11.3 THE SECOND MOMENT

Definitions:

The ***variance*** of the random variable X is $\text{Var}(X) = E(X - E(X))^2$.

A set of positive integers $\{x_1, x_2, \ldots, x_k\}$ has ***distinct sums*** if the quantities $\sum_{i \in S} x_i$ are all distinct for all subsets $S \subseteq \{1, 2, \ldots, k\}$.

Facts:

1. *Chebyshev's inequality*: For a random variable $X : \Omega \to \mathcal{R}$ and any $\lambda > 0$

$$Pr(|X - E(X)| > \lambda) \leq \tfrac{\text{Var}(X)}{\lambda^2}.$$

2. If X is a nonnegative integer-valued random variable, then

$$Pr(X = 0) \leq \tfrac{\text{Var}(X)}{E(X)^2}.$$

3. If $\text{Var}(X) = o(E(X)^2)$, then asymptotically almost surely $X \sim E(X)$.

Examples:

1. Erdős posed the question of estimating the maximum size $f(n)$ of a set $\{x_1, x_2, \ldots, x_k\}$ with distinct sums and $x_k \leq n$. We shall show that $f(n) \leq \log_2 n + \frac{1}{2}\log_2\log_2 n + O(1)$. Suppose $X = \{x_1, x_2, \ldots, x_k\}$ is a maximum sized set with distinct sums. Pick a random subset S of $\{1, 2, \ldots, k\}$ by selecting each element independently with probability 1/2. This subset yields the random sum $X_S = \sum_{i \in S} x_i$ with $E(X_S) = \frac{1}{2}(x_1 + x_2 + \cdots + x_k)$. Also, $\text{Var}(X_S) = \frac{1}{4}(x_1^2 + x_2^2 + \cdots + x_k^2) \leq \frac{n^2 k}{4}$, so by Chebyshev's inequality we have $Pr(|X_S - E(X_S)| < \lambda) \geq 1 - \frac{n^2 k}{4\lambda^2}$. Since X has distinct sums and there are 2^k distinct subsets of $\{x_1, x_2, \ldots, x_k\}$, it follows that for each integer r we have that $Pr(X_S = r)$ is either $\frac{1}{2^k}$ or 0, depending on whether r appears as a sum of some subset of X or not. This observation coupled with Chebyshev's inequality gives

$$1 - \tfrac{n^2 k}{4\lambda^2} \leq Pr(|X_S - E(X_S)| < \lambda) \leq \tfrac{2\lambda+1}{2^k}.$$

Optimizing for λ gives the desired result.

2. Given a set X of at least $4k^2$ distinct residue classes modulo a prime p, there exists an integer a such that $\{ax \pmod{p} \mid x \in X\}$ intersects every cyclic interval in $\{0, 1, \ldots, p-1\}$ of length at least p/k (see [AlKrNe95], [AlPe92]). To see this, we first note that if some shift $aX + b$ satisfies this property, then so does the set aX.

We start with a simple observation. Let $I_1, I_2, \ldots, I_{2k}$ be a (fixed) covering of $\{0, 1, \ldots, p-1\}$ by $2k$ intervals of length $\lceil p/2k \rceil$ each. Suppose that a set Y intersects each of these intervals I_j; then in particular, since every cyclic interval J of size at least p/k must contain some I_j it follows that $Y \cap J \neq \emptyset$. Select $a \in \{1, 2, \ldots, p-1\}$ and $b \in \{0, 1, \ldots, p-1\}$ uniformly and independently, and let $X_{a,b} = \{ax+b \mid x \in X\}$. Here the arithmetic is modulo p. Fix an interval I_j and consider the random variables X_x^j (for $x \in X$) which equal one if $ax + b \in I_j$ and zero otherwise. Setting $N_j = \sum_{x \in X} X_x^j = |X_{a,b} \cap I_j|$ we see that $E(N_j) = \sum_{x \in X} Pr(ax + b \in I_j) \geq 2k$. Furthermore, $\text{Var}(N_j) = \sum_{x \in X} \text{Var}(X_x) \leq 2k$. The equality in the above holds because the random variables X_x^j (as x varies over X) are pairwise independent, though they are not all mutually independent. Hence, by Chebyshev's inequality, $Pr(N_j = 0) < 1/2k$. In particular, the probability that $N_j = 0$ for some j is at most $\sum_j Pr(N_j = 0)$, and this is strictly less than 1. Consequently, there exist a, b such that $X_{a,b}$ intersects every I_j, and this completes the proof.

7.11.4 OCCURRENCE OF RARE EVENTS: THE LOCAL LEMMA

In all the examples seen so far, the probability of the "bad" event(s) is in fact negligible. But in order to prove that a "good" event occurs, we only need to show that the probability of the bad event is strictly less than one.

Definitions:

Suppose $E_1, E_2, \ldots, E_N$ are events in a probability space (Ω, Pr). A graph $\mathcal{D} = (\mathcal{V}, \mathcal{E})$ with vertex set $\mathcal{V} = \{E_i \mid i = 1, \ldots, N\}$ is called a ***dependency digraph*** of the events E_i if each E_i is independent of the set $\{E_j \mid (E_i, E_j) \notin \mathcal{E}\}$. In words, E_i is independent of all the events E_j whenever E_i and E_j are nonadjacent in $\mathcal{D}$. We write $i \sim j$ (resp. $i \not\sim j$) to denote $(E_i, E_j) \in \mathcal{D}$ (resp. $(E_i, E_j) \notin \mathcal{D}$).

Suppose graph G admits a partition $V = V_1 \cup V_2 \cup \cdots \cup V_r$ of its vertex set. We say a set $\mathcal{I}$ is an ***independent transversal*** for this partition if $\mathcal{I}$ contains exactly one element from each V_i and is independent in G.

Fix $k \geq 2$. For a k coloring $c : \mathcal{R} \to \{1, 2, \ldots, k\}$ of $\mathcal{R}$ and a fixed subset $T \subset \mathcal{R}$ we say that T is ***multicolored with respect to c*** if every color appears in the coloring induced on T.

A ***proper k-coloring*** of (the vertices of) a graph $G = (V, E)$ is a map $C : V \to \{1, 2, \ldots, k\}$ such that for adjacent vertices x and y we have $C(x) \neq C(y)$. For any integer $\beta > 1$ a proper vertex coloring C of G is ***β-frugal*** if for any vertex v and any color c there are at most β neighbors of v that are colored c.

Facts:

1. *Lovász Local Lemma - symmetric case*: Suppose $E_1, E_2, \ldots, E_N$ are events in a probability space (Ω, Pr) and $\mathcal{D}$ is a dependency graph for these events. Let d denote the maximum vertex degree in $\mathcal{D}$, and let $0 < p < 1$ be such that $Pr(E_i) \leq p$ for all i. If $ep(d + 1) \leq 1$, then

$$Pr\left(\overline{E_1} \wedge \overline{E_2} \wedge \cdots \wedge \overline{E_N}\right) > 0.$$

In particular, with positive probability, none of the events E_i occur. Here, $e \approx 2.71828$ denotes the Euler constant. [ErLo75]

2. *Lovász Local Lemma - general case*: Suppose $E_1, E_2, \ldots, E_N$ are events in a probability space (Ω, Pr) and $\mathcal{D}$ is a dependency graph for these events. Suppose there are real numbers $x_i, i = 1, \ldots, N$ satisfying $0 \le x_i < 1$ so that for each event E_i we have

$$Pr(E_i) \le x_i \prod_{j \not\sim i}(1 - x_j).$$

Then

$$Pr\left(\overline{E_1} \wedge \overline{E_2} \wedge \cdots \wedge \overline{E_N}\right) \ge \prod_{i=1}^{N}(1 - x_i) > 0.$$

Again, with positive probability, none of the events E_i occur. [ErLo75]

Examples:

1. *Independent transversals*: Suppose the graph G admits a vertex partition $V = V_1 \cup V_2 \cup \cdots \cup V_r$ and the maximum vertex degree in G equals d. Suppose further that each set V_i has size at least $2ed$. Then there exists an independent transversal in G for the partition $(V_1, V_2, \ldots, V_r)$. [Al88]

To see this, pick $v_i \in V_i$ independently and uniformly for each i. For each edge (x, y), let E_{xy} denote the event that both vertices x and y are selected. Our chosen set is an independent transversal if and only if for each edge $(x, y) \in E(G)$, the event E_{xy} does not occur. Consider the graph $\mathcal{D}$ whose vertex set consists of the edges of G in which two edges are adjacent in $\mathcal{D}$ if and only if they intersect. Then $\mathcal{D}$ is a dependency graph for the events E_{xy} for each $(x, y) \in E(G)$. To use the local lemma, note that the probability that both vertices of any fixed edge $e \in E(G)$ are included in the transversal is at most $1/(2ed)^2$, and since each vertex in G has degree at most d, the maximum degree of $\mathcal{D}$ is at most $2d$. Hence by the local lemma, it follows that with positive probability, none of the events E_{xy} occur, since $\frac{e(2d+1)}{(2ed)^2} \le 1$.

2. *A question of Straus*: Does there exist $m(k) > 0$ such that for any given fixed S of size m, there exists a k-coloring of $\mathcal{R}$ such that every translate $x + S$, $x \in \mathcal{R}$ is multicolored? It turns out that $m(k) = (3 + o(1))k \log k$ suffices. [ErLo75]

To see this, first let X be a finite set of real numbers and let $\mathcal{X} = \bigcup_{x \in X}(x + S)$. Now color every element of $\mathcal{X}$ from $\{1, 2, \ldots, k\}$ independently and uniformly. We claim that $Pr(\wedge_{x \in X}((x + S)$ is not multicolored$)) > 0$. Fix x and denote the event that $x + S$ is not multicolored by $\mathcal{E}_x$. Then

$$Pr(\mathcal{E}_x) \le k\left(1 - \tfrac{1}{k}\right)^m.$$

Moreover, $\mathcal{E}_x$ is independent of all $\mathcal{E}_y$ as long as $(x + S) \cap (y + S) = \emptyset$. Hence by the local lemma, we are done provided $ekm^2\left(1 - \frac{1}{k}\right)^m \le 1$. It is a routine calculation to see that this holds if $m > (3 + o(1))k \log k$. Hence it follows that for every finite set X, there exists a color choice for the elements of $\mathcal{X}$ such that each translate $x + S$ is multicolored. This coupled with a compactness argument shows that the same result holds for $X = \mathcal{R}$.

3. *Frugal colorings*: Suppose G is a regular graph of degree Δ, i.e., every vertex of G has degree Δ. Then for Δ sufficiently large, there is a proper β-frugal coloring of G using at most $O(\Delta^{1+\frac{1}{\beta}})$ colors [HiMoRe97]. To see this, as always, color each vertex uniformly and independently from the set of colors $\{1, 2, \ldots, N\}$ where $N = m\Delta^{1+\frac{1}{\beta}}$ for some suitable constant m that shall be determined later. For each edge uv we consider the event A_{uv} that both u and v have been assigned the same color. Likewise, for each independent set $v_1, v_2, \ldots, v_{\beta+1}$ of vertices that are also neighbors of some vertex x in G, we consider the event $B(v_1, v_2, \ldots, v_{\beta+1})$ that all the vertices $v_1, \ldots, v_{\beta+1}$ have been assigned the same color. This random coloring describes a frugal coloring if none of the events A_{uv} or $B(v_1, v_2, \ldots, v_{\beta+1})$ occur. Note that each event A_{uv} is independent of all other A_{wz} as long as $\{u, v\} \cap \{w, z\} = \emptyset$ and independent of

$B(v_1, v_2, \dots, v_{\beta+1})$ if $\{v_1, v_2, \dots, v_{\beta+1}\} \cap \{u, v\} = \emptyset$. Similarly, $B(v_1, v_2, \dots, v_{\beta+1})$ is independent of $B(w_1, w_2, \dots, w_{\beta+1})$ if $\{v_1, v_2, \dots, v_{\beta+1}\} \cap \{w_1, w_2, \dots, w_{\beta+1}\} = \emptyset$.

Let $x = 2/N$ and $y = 2/N^\beta$. Following a few routine calculations, it follows that

$$Pr(A_{uv}) \le x(1-x)^{2\Delta-2}(1-y)^{2\Delta\binom{\Delta}{\beta}}$$

and

$$Pr(B(v_1, v_2, \dots, v_{\beta+1})) \le y(1-x)^{(\beta+1)\Delta}(1-y)^{(\beta+1)\Delta\binom{\Delta}{\beta}},$$

for $m = 12$, so by the general version of the local lemma the proof follows.

To see how good the above bound is, consider the following bipartite graphs G_β, for any integer $\beta > 1$. The vertex set consists of the 1-dimensional subspaces (*points*) and $(\beta+1)$-dimensional subspaces ($\beta + 1$ *flats*) of a $(\beta+2)$-dimensional vector space over a finite field of q elements. A point p and a $\beta + 1$ flat Π are adjacent in G_β if p is a subspace of Π. Note that no color can be used more than β times in a β-frugal coloring. Since any $\beta + 1$ distinct points together lie in a $(\beta+1)$-dimensional flat, the number of colors needed is at least $(q^{\beta+1} + q^\beta + \cdots + 1)/\beta$. Since the maximum degree in G_β equals $q^\beta + q^{\beta-1} + \cdots + q + 1$, the number of colors needed in a β-frugal coloring is at least $\Omega(\Delta^{1+1/\beta})$. Hence the result above is tight up to the constant factor C.

7.11.5 BASIC CONCENTRATION INEQUALITIES

Definitions:

For a hypergraph $\mathcal{H}$, a 2-coloring χ of the vertices of $\mathcal{H}$, and an edge $e \in \mathcal{E}(\mathcal{H})$ the ***discrepancy*** $D(e)$ of the edge e is the absolute value of the difference between the number of vertices in the two color classes. The ***discrepancy of $\mathcal{H}$ with respect to χ*** denoted $D(\mathcal{H}, \chi)$ is defined as the maximum $D(e)$ as e ranges over the edges in $\mathcal{H}$. The ***discrepancy of the hypergraph $\mathcal{H}$*** is $D(\mathcal{H}) = \min_\chi D(\mathcal{H}, \chi)$ where χ ranges over all 2-colorings of $\mathcal{H}$.

For graphs $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ the ***Cartesian product*** of G_1 and G_2 denoted $G_1 \Box G_2$ is the graph with vertex set $V_1 \times V_2$ where vertices (u_1, u_2) and (v_1, v_2) are adjacent if either $u_1 = v_1$ and $(u_2, v_2) \in E_2$ or $(u_1, v_1) \in E_1$ and $u_2 = v_2$. The Cartesian product of graphs is associative and commutative.

For vertices u, v in a graph G, the ***distance*** $d_G(u, v)$ between u and v in G is the length of a shortest u-v path in G. If u and v lie in different connected components, then we write $d_G(u, v) = \infty$. For a subset of vertices U, $d_G(x, U) = \min_{u \in U} d_G(x, u)$.

Facts:

1. *Chernoff bounds* [Ch52]: Suppose X is a binomial random variable $B(n, p)$, and $\lambda = E(X) = np$. Then for $t \ge 0$

$$\begin{aligned} Pr(X \ge E(X) + t) &\le \exp\left(-\tfrac{t^2}{2(\lambda + t/3)}\right), \\ Pr(X \ge E(X) - t) &\le \exp\left(-\tfrac{t^2}{2\lambda}\right). \end{aligned}$$

2. *Chernoff bounds - general case*: If $X_i \sim Ber(p_i)$, $i = 1, \dots, n$ and X_i are mutually independent Bernoulli random variables defined on Ω with parameters p_i, then the same inequalities as above hold for $X = \sum_{i=1}^n X_i$ with $\lambda = E(X) = \sum_{i=1}^n p_i$.

3. *Simple concentration bound*: Suppose $X_1, X_2, \ldots, X_n$ are independent random variables in (Ω, Pr) and suppose $f(x_1, x_2, \ldots, x_n) : \mathcal{R}^n \to \mathcal{R}$ is a real-valued function that satisfies the *Lipschitz* condition, i.e., $|f(x_1, x_2, \ldots, x_i, \ldots, x_n) - f(x_1, x_2, \ldots, x_i', \ldots, x_n)| \leq c_i$ for each i and for some $c_i > 0$. If $X = f(X_1, X_2, \ldots, X_n)$, then

$$Pr(|X - E(X)| > t) \leq 2\exp\left(-\frac{t^2}{2\sum_{i=1}^n c_i^2}\right).$$

4. *Azuma's inequality* [Az67]: Let $X_0, X_1, \ldots, X_n$ be a martingale such that $|X_{i+1} - X_i| \leq c_i$ for each i and some reals $c_i > 0$. Then for $\lambda > 0$

$$\begin{aligned} Pr(X_n - X_0 > \lambda) &\leq \exp\left(-\frac{\lambda^2}{2\sum_{i=1}^n c_i^2}\right), \\ Pr(X_n - X_0 < -\lambda) &\leq \exp\left(-\frac{\lambda^2}{2\sum_{i=1}^n c_i^2}\right). \end{aligned}$$

Examples:

1. *Discrepancy*: Let $\mathcal{H}$ be a k-uniform hypergraph with k edges. Color each vertex uniformly and independently using one of the two colors. We shall show that with positive probability, this random coloring χ satisfies $D(\mathcal{H}, \chi) \leq \sqrt{8k\log k}$, so that $D(\mathcal{H}) \leq \sqrt{8k\log k}$. For each edge e, we have by the Chernoff bounds that $Pr(D(e) > 2t) \leq 2e^{-t^2/(3k/2)} < \frac{1}{k}$ for $t = \sqrt{k\log k}$. Hence the probability that $D(e)$ exceeds $2t$ for some edge $e \in \mathcal{H}$ is less than 1, so that with positive probability, χ has the desired property.

2. *A result of Erdős, Silverman, and Stein* [ErSiSt83]: Let Π_n be a projective plane of order n. There exists a subset S of points, and absolute constants k, K such that $k\log n \leq |L \cap S| \leq K\log n$ for every line L in Π_n.

To see this, choose S at random, with each point x placed in S with probability $p = \frac{f(n)}{n+1}$, for some $f(n)$ to be determined later. Fix a line L, and let $S_L = |S \cap L|$. Note that $E(S_L) = (n+1)p = f(n)$. By the Chernoff bound, $Pr[|S_L - f(n)| > f(n)] < 2e^{-f(n)/3}$. Since Π_n contains $n^2 + n + 1$ lines,

$$Pr\,(\text{there exists } L \,\text{such that}\, |S_l - f(n)| > f(n)) < 4e^{-f(n)/3}n^2.$$

Therefore, if $e^{f(n)/3} > 4n^2$, the desired S exists. It is easy to check that $f(n) = 3\log 4n^2$ works for the aforementioned argument.

3. Consider the graph $G_{r,n} = K_r^{\Box n}$, the r-fold Cartesian product of the complete graph K_r. For $\epsilon > 0$, let $W \subset G_{r,n}$ be a subset of size at least ϵr^n and let U be the set of vertices of $G_{r,n}$ whose distance from W is greater than $2\sqrt{n\log n}$. We claim that $|U| \leq \frac{Cr^n}{n^2}$ for some absolute constant C that depends only on ϵ.

Suppose x is a vertex of $G_{r,n}$ obtained by choosing $v_1, v_2, \ldots, v_n$ uniformly and independently among the vertices of K_r. Consider the *Doob martingale process* $\{Y_i\}_{i=0,1,\ldots,n}$ of exposing one v_i at a time, i.e., consider the random variables $Y_i = E(d(x, W)|v_1, v_2, \ldots, v_i)$ for $i = 0, 1, \ldots, n$ (here by convention, $Y_0 = E(d(x, W)))$ where we write $d(x, W) = d_G(x, W)$ for simplicity. $\{Y_i\}$ is a martingale with $c_i = 1$ for each i since altering v_i changes the value of Y_{i-1} by at most one. By Azuma's inequality, we have $Pr(d(x, W) - E(d(x, W)) < -c\sqrt{n}) \leq e^{-c^2/2}$. Setting $c < \sqrt{2\log(1/\epsilon)}$ we see that $Pr(d(x, W) < E(d(x, W) - c\sqrt{n}) < \epsilon$. However, note that since $|W| \geq \epsilon r^n$, we have $Pr(d(x, W) = 0) \geq \epsilon$, so in particular, $E(d(x, W) < \sqrt{2\log(1/\epsilon)n}$. On the other hand, we also have $Pr(d(x, W) - E(d(x, W)) > c\sqrt{n}) \leq e^{-c^2/2}$, so setting $c = 2\sqrt{\log n}$ we get $Pr(d(x, W) > 2\sqrt{n\log n}) \leq O(1/n^2)$. This completes the proof.

7.11.6 CORRELATION INEQUALITIES

Definitions:

A family of subsets $\mathcal{A}$ of $\{1, 2, \ldots, n\}$ is called an ***upset*** if whenever $A \in \mathcal{A}$ and $A \subset A'$ then $A' \in \mathcal{A}$ as well. A family of subsets $\mathcal{A}$ of $\{1, 2, \ldots, n\}$ is called a ***downset*** if whenever $A \in \mathcal{A}$ and $A' \subset A$ then $A' \in \mathcal{A}$ as well.

Suppose L is a finite distributive lattice, i.e., a lattice in which for any $x, y, z \in L$ we have $(x \wedge y) \vee z = (x \vee z) \wedge (y \vee z)$. A function $\mu : L \to \mathcal{R}^+$ is called ***log-supermodular*** if $\mu(x)\mu(y) \le \mu(x \vee y)\mu(x \wedge y)$.

A real-valued function f defined on a finite distributive lattice is called ***increasing*** if $f(x) \le f(y)$ whenever $x \le y$. Similarly, a function f is called ***decreasing*** if $f(x) \ge f(y)$ whenever $x \le y$.

Facts:

1. *Four function theorem* [AhDa78]: Suppose $\alpha, \beta, \gamma, \delta$ are nonnegative real-valued functions defined on the set of all subsets of $\{1, 2, \ldots, n\}$ and suppose for any sets $A, B \subset \{1, 2, \ldots, n\}$

$$\alpha(A)\beta(B) \le \gamma(A \cup B)\delta(A \cap B)$$

holds. Then for any families of sets $\mathcal{A}, \mathcal{B}$

$$\alpha(\mathcal{A})\beta(\mathcal{B}) \le \gamma(\mathcal{A} \cup \mathcal{B})\delta(\mathcal{A} \cap \mathcal{B}),$$

where for any function ϕ, $\phi(\mathcal{A})$ denotes the sum $\sum_{A \in A} \phi(A)$.

2. *Four function theorem - lattice version*: Suppose $\alpha, \beta, \gamma, \delta$ are nonnegative real-valued functions defined on the distributive lattice L and suppose that for any $a, b \in L$

$$\alpha(a)\beta(b) \le \gamma(a \vee b)\delta(a \wedge b).$$

Then for any subsets $A, B \subset L$

$$\alpha(A)\beta(B) \le \gamma(A \vee B)\delta(A \wedge B),$$

where $A \vee B = \{a \vee b \mid a \in A,\ b \in B\}$ and $A \wedge B = \{a \wedge b \mid a \in A,\ b \in B\}$.

3. *FKG inequality* [FoKaGi71]: Let L be a finite distributive lattice and let $\mu : L \to \mathcal{R}^+$ be a log-supermodular function. Then for any two increasing functions f, g

$$\left(\sum_{x \in L} \mu(x) f(x)\right) \left(\sum_{x \in L} g(x)\mu(x)\right) \le \left(\sum_{x \in L} \mu(x) f(x) g(x)\right) \left(\sum_{x \in L} \mu(x)\right).$$

4. *Correlation inequalities*: Suppose $\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{D}$ are families of subsets of $\{1, 2, \ldots, n\}$ with $\mathcal{A}, \mathcal{B}$ being upsets and $\mathcal{C}, \mathcal{D}$ being downsets. Pick a random subset R of $\{1, 2, \ldots, n\}$ by picking each $i \in \{1, 2, \ldots, n\}$ independently with probability $0 \le p_i < 1$. Then

$$\begin{aligned}
Pr(R \in \mathcal{A} \cap \mathcal{B}) &\ge Pr(R \in \mathcal{A}) \cdot Pr(A \in \mathcal{B}),\\
Pr(R \in \mathcal{C} \cap \mathcal{D}) &\ge Pr(R \in \mathcal{C}) \cdot Pr(R \in \mathcal{D}),\\
Pr(R \in \mathcal{A} \cap \mathcal{C}) &\le Pr(R \in \mathcal{A}) \cdot Pr(R \in \mathcal{C}).
\end{aligned}$$

Examples:

1. Suppose $0 < \alpha_1 \le \alpha_2 \le \cdots \le \alpha_n$ and $0 < \beta_1 \le \beta_2 \le \cdots \le \beta_n$ are increasing sequences of positive real numbers. Then

$$n \sum_i \alpha_i \beta_{n+1-i} \le \left(\sum_i \alpha_i\right)\left(\sum_i \beta_i\right) \le n \sum_i \alpha_i \beta_i.$$

To prove the first inequality, we use induction on n; if the inequality holds for $n-1$, then applying the inequality for the sequences $\mathfrak{a}_i = (\alpha_1, \alpha_2, \ldots, \alpha_{i-1}, \alpha_{i+1}, \ldots, \alpha_n)$ and $\mathfrak{b}_i = (\beta_1, \beta_2, \ldots, \beta_{n-i}, \beta_{n-i+2}, \ldots, \beta_n)$ and summing these inequalities as i ranges over $1, 2, \ldots, n$, we get

$$\sum_i (A - \alpha_i)(B - \beta_{n+1-i}) \ge (n-1)^2 \sum_i \alpha_i \beta_{n+1-i},$$

where $A = \sum_i \alpha_i, B = \sum_i \beta_i$. This inequality simplifies to $(n-2)AB + \sum_i \alpha_i \beta_{n+1-i} \ge (n-1)^2 \sum_i \alpha_i \beta_{n+1-i}$, which establishes the inductive hypothesis. For the second inequality, consider the distributive lattice $L = \{1, 2, \ldots, n\}$ with $i \vee j = \max\{i, j\}$, $i \wedge j = \min\{i, j\}$. It is easy to check that $\alpha(i) = \alpha_i, \beta(i) = \beta_i, \gamma(k) = \max\{\alpha_i \beta_j \mid i \vee j = k\}$, $\delta(i) = 1$ satisfy the hypotheses of the four function theorem. Furthermore, since the sequences α_i, β_i are nonnegative and increasing we have $\gamma(i) \le \alpha_i \beta_i$. Now the four function theorem gives $AB \le \sum_i n\gamma(i) \le n \sum_i \alpha_i \beta_i$ which is what we seek.

2. Suppose $\mathcal{A}$ is a family of subsets of $\{1, 2, \ldots, n\}$ such that for any $A, B \in \mathcal{A}$ both $A \cap B \ne \emptyset$ and $A \cup B \ne \{1, 2, \ldots, n\}$ hold. Then $|\mathcal{A}| \le 2^{n-2}$. To see why, let $\mathcal{C}$ be a maximal intersecting family containing $\mathcal{A}$, and let $\mathcal{D}$ be a maximal family containing $\mathcal{A}$ with no two sets having $\{1, 2, \ldots, n\}$ as their union. Note that the maximality of $\mathcal{C}$ and $\mathcal{D}$ implies that $\mathcal{C}$ is an upset and $\mathcal{D}$ is a downset. Since $\mathcal{A} \subset \mathcal{C} \cap \mathcal{D}$, by the correlation inequalities

$$|\mathcal{A}| \le |\mathcal{C} \cap \mathcal{D}| \le \tfrac{|\mathcal{C}| \cdot |\mathcal{D}|}{2^n} = 2^{n-2}.$$

This is also clearly best possible, e.g., consider the family $\mathcal{A} = \{A \mid 1 \in A,\ n \notin A\}$.

3. Suppose $\mathcal{A}_1, \mathcal{A}_2, \ldots, \mathcal{A}_k$ (for $k \ge 1$) are intersecting families on $\{1, 2, \ldots, n\}$. Then how large can $|\bigcup_{i=1}^k \mathcal{A}_i|$ be? Clearly, if we set $\mathcal{A}_i$ to be the intersecting family of all subsets of $\{1, 2, \ldots, n\}$ containing i, then $\bigcup_{i=1}^k \mathcal{A}_i$ consists of all those sets that contain at least one of the elements of $\{1, \ldots, k\}$, so clearly $|\bigcup_{i=1}^k \mathcal{A}_i| = 2^n - 2^{n-k}$. We claim that this is indeed best possible. For $k = 1$ this follows since for any set $A \subset \{1, 2, \ldots, n\}$ we must have $|\mathcal{A} \cap \{A, \overline{A}\}| \le 1$, so an intersecting family of $\{1, 2, \ldots, n\}$ contains at most 2^{n-1} sets. In general, let $\mathcal{B} = \bigcup_{i=1}^{k-1} \mathcal{A}_i$. Since each $\mathcal{A}_i$ is an intersecting family, we may assume that each $\mathcal{A}_i$ is an upset since adding larger sets will not violate the property that $\mathcal{A}_i$ is intersecting. Since each $\mathcal{A}_i$ is an upset, it follows that $\mathcal{B}$ is an upset as well. Also, without loss of generality, assume that $\mathcal{A} := \mathcal{A}_k$ is a maximal intersecting family, so $|\mathcal{A}| = 2^{n-1}$. Let us pick a set T uniformly at random from $\{1, 2, \ldots, n\}$. Then

$$\begin{aligned}
Pr(T \in \mathcal{A} \cup \mathcal{B}) &= Pr(T \in \mathcal{A}) + Pr(T \in \mathcal{B}) - Pr(T \in \mathcal{A} \cap \mathcal{B}) \\
&\le \tfrac{1}{2} + Pr(T \in \mathcal{B}) - \tfrac{1}{2}\, Pr(T \in \mathcal{B}) \\
&= \tfrac{1}{2} + \tfrac{1}{2}\, Pr(T \in \mathcal{B}) \\
&\le \tfrac{1}{2} + \tfrac{1}{2}\left(1 - \tfrac{1}{2^{k-1}}\right) = 1 - \tfrac{1}{2^k},
\end{aligned}$$

where the first inequality is a consequence of the correlation inequality applied to the upsets $\mathcal{A}, \mathcal{B}$, and the last inequality follows by induction on k. But this translates as $|\bigcup \mathcal{A}_i| \le 2^n(1 - \frac{1}{2^k}) = 2^n - 2^{n-k}$.

GRAPH THEORY

INTRODUCTION

A graph is conceptually a set of points and a set of lines (possibly curved) joining one point to another (or to itself). Graph theory has its origins in many disciplines. Graphs are natural mathematical models of physical situations in which the points represent either objects or locations and the lines represent connections. Graphs are also used to model sociological and abstract situations in which each line represents a relationship between the entities represented by the points. Applications of graphs are wide-ranging—in areas such as circuit design, communications networks, ecology, engineering, operations research, counting, probability, set theory, information theory, and sociology.

This chapter contains an extensive treatment of the various properties of graphs. Further topics in graph theory are covered in Chapter 9 (Trees) and in Chapter 10 (Networks and Flows).

GLOSSARY

acyclic digraph: a digraph containing no directed cycles.

acyclic graph: a graph containing no cycles.

adjacency matrix (of a digraph): the square matrix A with $A[i,j]$ = the number of edges from vertex v_i to vertex v_j.

adjacency matrix (of a graph): the square matrix A with $A[i,j]$ = the number of edges between vertices v_i and v_j.

adjacent edges: two edges with a common endpoint.

adjacent vertex (in a digraph) from [to] a vertex u: a vertex v such that there is an arc from u to v [to u from v].

adjacent vertices: two vertices that are endpoints of the same edge.

admittance matrix: See *Laplacian.*

algebraic specification (of a graph): a specification that uses group elements in the vertex and edge names and uses the group operation in the incidence rule.

almost every (***a.e.***) ***graph has property*** $\boldsymbol{P}$: the statement that the probability that a random n-vertex graph has property P approaches 1 as $n \to \infty$.

antichain: a hypergraph in which no edge contains any other edge.

antihole: an induced subgraph whose complement is isomorphic to the cycle C_k with $k \geq 4$.

antimagic graph: a graph whose q edges can be labeled with distinct integers from 1 to q such that the sums of the labels of the edges incident to each vertex are distinct.

arc: another name for a directed edge of a graph.

articulation point: synonym for cutpoint.

attachment of a bridge of a subgraph: for a bridge B of a subgraph H, a vertex of $B \cap H$.

attribute (of the edge-set or vertex-set): any additional feature, such as length, cost, or color, that enables a graph to model a real problem.

automorphism: for a graph or digraph, an isomorphism from the graph or digraph to itself.

automorphism group: the collection $\mathcal{A}ut(G)$ of all automorphisms of a graph or digraph G under the operation of composition.

basis (for a digraph): a set of vertices V' of the digraph such that every vertex not in V' is reachable from V' and no proper subset of V' has this property.

Berge graph: a graph that has no odd hole and no odd antihole.

bipartite: property of a graph that its vertices can be partitioned into two subsets, called "parts", so that no two vertices within the same part are adjacent.

block: in a graph, a maximal nonseparable subgraph.

bond: a minimal disconnecting set of edges.

boundary (of a region of a graph imbedded in a surface): for region R, the subgraph containing all vertices and edges incident on R; denoted by ∂R.

boundary (of a set of vertices): for F a subset of vertices in a graph, the set of edges that have one endpoint inside F and one endpoint outside F; denoted by ∂F.

bouquet: a graph B_n with one vertex and n self-loops.

bridge (***edge***): a cut-edge.

cactus: a connected graph in which every block is either an edge or a cycle.

Cartesian product: for graphs G and H, the graph $G \square H$ that has vertex set $V_G \times V_H$ and edge set $\{(g,h)(g',h') \mid gg' \in E_G \text{ and } h = h', \text{ or}, g = g' \text{ and } hh' \in E_H\}$.

caterpillar: a tree that contains a path such that every edge has one or both endpoints in that path.

Cayley graph (***or digraph***): a graph that depicts a group with a prescribed set of generators; the vertices represent group elements, and the edges or arcs (often "colored" by the generators) represent the product rule.

cellular imbedding: an imbedding such that every region is equivalent to the interior of a (unit) disk.

center: in a connected graph, the set of vertices of minimum eccentricity.

chain: a simple hypergraph in which, given any pair of edges, one edge contains the other.

characteristic polynomial (of a graph): the characteristic polynomial of its adjacency matrix.

chromatic index (of a graph or hypergraph): See *edge chromatic number*.

chromatic number (of a graph): the minimum number $\chi(G)$ of colors needed to color the vertices of a graph G so that no vertex is adjacent to a vertex of the same color.

chromatic number (of a hypergraph): the smallest number $\chi(H)$ of independent sets required to partition the vertex set of H.

chromatic number (of a map): the minimum number $\chi(M)$ of colors needed to color the regions of the map M so that no color meets itself across an edge.

chromatic number (of a surface): the largest map chromatic number $\chi(S)$ taken over all maps on the surface S.

chromatically n-critical graph: an n-chromatic graph G such that $\chi(G-e) = n-1$ no matter what edge e is removed.

circuit: synonym for a closed walk, a closed trail, or a cycle, depending on the context.

clique (in a graph): a complete subgraph.

clique (in a hypergraph): a simple hypergraph such that every pair of edges has nonempty intersection.

clique number (of a graph): the number $\omega(G)$ of vertices of a largest clique in the graph G.

clique number (of a hypergraph): the largest number $\omega(H)$ of edges of any partial clique in the hypergraph H.

clique partition number: for a hypergraph H, the smallest number $cp(H)$ of cliques required to partition the edge set.

closed walk (***trail or path***): a walk, trail, or path whose origin and terminus are the same.

n-colorable graph: a graph having a vertex coloring using at most n colors.

n-colorable map: a map having a coloring using at most n colors.

comparability graph: a graph that admits a transitive orientation.

complement (of a graph): the graph $\overline{G}$ with the same vertex set as G, but in which two vertices are adjacent if and only if they are not adjacent in G.

complete bipartite graph: a bipartite graph $K_{r,s}$ whose vertex set has two parts, of sizes r and s, respectively, such that every vertex in one part is adjacent to every vertex in the other part.

complete graph: the simple graph K_n with n vertices in which every pair of vertices is adjacent.

complete hypergraph: the simple n-vertex hypergraph K_n^* in which every subset of vertices is an edge.

complete multipartite (or ***k-partite***) ***graph***: a k-partite simple graph such that *every* pair of vertices from different parts is joined by an edge; denoted by $K_{n_1,\ldots,n_k}$, where $n_1, \ldots, n_k$ are the sizes of the parts.

complete r-uniform hypergraph: the simple n-vertex hypergraph K_n^r in which every r-element subset is an edge.

complete set of invariants: a set of invariants that determine a graph or digraph up to isomorphism.

component: for a graph, a maximal connected subgraph.

connected: property of a graph that each pair of vertices is joined by a path.

connectivity: See *vertex connectivity.*

contraction: for a graph, the result of a sequence of elementary contractions.

contraction, ***elementary*** (of a graph): the operation of shrinking an edge to a point, so that its endpoints are merged, without otherwise changing the graph.

contraction, ***elementary*** (of a simple graph): replacing two adjacent vertices u and v by one vertex adjacent to all other vertices to which u or v were adjacent.

converse: for a digraph, the digraph obtained by reversing the direction of every arc.

corona (of a graph): for a graph H, the graph obtained by adding for each vertex v of H a new vertex v' and the edge vv'; denoted by $H \circ K_1$.

crosscap: a subportion of a surface that forms a Möbius band.

crosscap number (of a nonorientable surface): for a nonorientable surface S, the maximum number $\overline{\gamma}(S)$ of disjoint crosscaps one can find on the surface. The nonorientable surface of crosscap number k is denoted N_k.

crossing number: for a graph G, the minimum number $\nu(G)$ of edge-crossings taken over all normalized planar drawings of G.

cube graph: See *hypercube graph.*

cut-edge: for a graph G, an edge e such that $G - e$ has more components than G.

cut-vertex (or ***cutpoint***): for a graph G, a vertex v such that $G - v$ has more components than G.

cycle: a closed path of positive length. See also *k-cycle.*

cycle, ***directed***: a closed directed walk in which all the vertices except the first and last are distinct.

cycle graph: a graph C_n with n vertices that is 2-regular and connected.

cycle rank: for a connected graph G, the number $\beta_1(G)$ of edges in the complement of a spanning tree for G; that is, $|E_G| - |V_G| + 1$.

DAG: an acronym for directed acyclic graph.

degree (of a vertex in a graph): for a vertex v, the number $\deg(v)$ of instances of v as an endpoint; that is, the number of proper edges incident on v plus twice the number of loops at v.

degree (of a hypergraph vertex): for a vertex x, the number $\deg(x)$ of hypergraph edges containing x.

degree sequence of a graph: the sequence of the degrees of its vertices, usually sorted.

deleting an edge from a graph: given a graph G and an edge e of G, the operation that results in the subgraph $G-e$, which contains all the vertices of G and all edges except e.

deleting a vertex from a graph: given a graph G and a vertex v of G, the operation that results in the subgraph $G-v$, which contains all vertices of G except v and all the edges of G except those incident with v.

diameter: for a connected graph, the maximum distance between two of its vertices.

diconnected digraph: See *strongly connected digraph*.

digraph (or ***directed graph***): a graph in which every edge is directed.

dipole: the graph D_n with two vertices and a multi-edge of multiplicity n joining them.

direct product: for graphs G and H, the graph $G \times H$ that has vertex set $V_G \times V_H$ and edge set $\{(g,h)(g',h') \mid gg' \in E_G \text{ and } hh' \in E_H\}$.

directed cycle, ***path***, ***trail***, ***walk***: See *cycle*, *path*, etc.

directed graph: See *digraph*.

direction (on an edge): a sense of forward progression from one end to the other, usually marked by an arrowhead.

disconnected (digraph): a digraph whose underlying graph is disconnected.

disconnecting set of edges (in a connected graph): a set whose removal yields a nonconnected graph.

disconnecting set of vertices (in a connected graph): a set whose removal yields a nonconnected graph.

distance (in a connected graph): for two vertices v and w, the length $d(v,w)$ of a shortest path between them.

distance (in a connected digraph): for two vertices v and w, the length $d(v,w)$ of a shortest directed path between them.

dodecahedral graph: the 1-skeleton of the dodecahedron, which is a 3-dimensional polyhedron whose 12 faces are all pentagons; this graph has 20 vertices, each of degree 3, and 30 edges.

dominating set (of a graph): a set S of vertices such that every vertex not in S is adjacent to a vertex in S.

domination number (of a graph): the minimum cardinality $\gamma(G)$ of a dominating set in graph G.

downset: a simple hypergraph in which every subset of every edge is also an edge of the hypergraph.

dual graph imbedding: a new graph imbedding obtained by placing a dual vertex in the interior of each existing ("primal") region and by drawing a dual edge through each existing ("primal") edge connecting the dual vertices on its opposite sides.

dual (of a hypergraph): for a hypergraph H, the hypergraph H^* whose incidence matrix is the transpose of the incidence matrix $M(H)$.

eccentricity (of a vertex): for a vertex v in a connected graph, the maximum distance from v to another vertex.

edge: a line, either joining one *vertex* to another or joining a *vertex* to itself; an element of the second constituent set of a *graph*.

edge chromatic number (of a graph): for a graph G, the smallest number n such that G is n-edge colorable, written $\chi_1(G)$.

edge chromatic number (of a hypergraph): for a hypergraph H, the smallest number $q(H)$ of matchings required to partition the edge set of H.

n-edge colorable: property of a graph that it has an edge coloring using at most n colors.

edge coloring: an assignment of colors to the edges of a graph so that adjacent edges receive different colors. See also *n-edge colorable.*

edge connectivity: the cardinality $\kappa'(G)$ of a smallest disconnecting set of edges in graph G. See also *k-edge-connected.*

edge cut: See *disconnecting set.*

edge independence number: the cardinality $\alpha_1(G)$ of a largest independent set of edges in graph G.

edge-complement: See *complement.*

edge-deleted subgraph: any subgraph obtained from a graph by removing a single edge.

edge-reconstructible graph: a graph that is uniquely determined by its collection of edge-deleted subgraphs.

edge-reconstructible invariant: an invariant that is uniquely determined by the collection of edge-deleted subgraphs of a graph.

eigenvalue (of a graph): a number λ such that $Ax = \lambda x$ for some nonzero vector x, where A is the adjacency matrix.

eigenvector (of a graph): a nonzero vector x such that $Ax = \lambda x$, where A is the adjacency matrix.

embedding: See *imbedding.*

empty graph: sometimes, a graph with no edges; other times, a graph with no vertices or edges. See *null graph.*

endpoints (of an edge): the *vertices* that are joined by the edge.

Euler characteristic: for a surface S, the invariant $\chi(S)$ given by $2 - 2g$ for the orientable surface of genus g, and $2 - k$ for the nonorientable surface of crosscap number k.

Euler tour: a closed Euler trail.

Euler trail: a trail that contains all the edges of the graph.

Eulerian graph: a graph that has an Euler tour.

expander family: a sequence of graphs, all of the same regularity and whose orders grow to infinity, for which there exists $\epsilon > 0$ such that the isoperimetric constant is at least ϵ for all the graphs.

exterior region: in a planar graph drawing, the region that extends to infinity.

extremal graph: for a set $\mathcal{G}$ of graphs and an integer n, an n-vertex graph with $ex(\mathcal{G};n)$ edges that contains no member of $\mathcal{G}$.

extremal number: for a set $\mathcal{G}$ of graphs, the greatest number $ex(\mathcal{G};n)$ of edges in any n-vertex simple graph that does *not* contain some member of $\mathcal{G}$ as a subgraph.

face: for an imbedding of a graph in a surface, a region plus its boundary.

1-*factorization*: a partition of the edges of a graph into 1-factors.

forest: a graph without a cycle.

four color theorem: the fact that every planar map can be properly colored with at most four colors, proved in 1976.

general graph: another name for a graph that might have loops.

generating set (for a group): a subset of group elements such that every group element is a product of generators.

genus (of a graph): the minimum genus of a surface in which the graph has a cellular imbedding.

genus (of an orientable surface): for a surface S, the maximum number $\gamma(S)$ of disjoint handles one can find on the surface; the orientable surface of genus g is denoted S_g.

girth: for a graph, the number of edges in a shortest cycle, if there is at least one cycle; undefined if the graph has no cycles.

graceful graph: a graph for which there exists an injection f from the vertices to the set $\{0,1,\ldots,q\}$, where q is the number of edges, such that when each edge xy is assigned the label $|f(x)-f(y)|$, the resulting edge labels are distinct.

graph: a set V of vertices and a set E of edges such that all the endpoints of edges in E are contained in V, written $G=(V,E)$, (V_G,E_G), or $(V(G),E(G))$.

graph model: any configuration with underlying graph structure, and possibly some additional attributes on its edges and/or vertices, such as length, direction, or cost.

graph sum: for graphs G and H, the graph $G+H$ whose vertex set and edge set are, respectively, the disjoint union of the vertex sets and the edge sets of G and H.

graphical sequence: a sequence of nonnegative integers such that there is a *simple graph* for which it is the *degree sequence.*

Gray code: a cyclic ordering of all 2^k bitstrings of length k, such that each bitstring differs from the next in exactly one bit entry.

Hamilton cycle: a spanning cycle; that is, a cycle including each vertex of a graph exactly once.

Hamilton path: a path that includes all the vertices of a graph.

Hamiltonian graph: a graph that contains a Hamiltonian cycle.

harmonious graph: a graph for which there is an injection f from the vertices to $\mathcal{Z}_q$, where q is the number of edges, such that when each edge xy is assigned the label $f(x)+f(y)$ (mod q), the resulting edge labels are distinct; when the graph is a tree, exactly one label may be used on two vertices.

head (of an arc): the vertex the arc goes to.

Hoffman polynomial (of a graph): a polynomial $p(x)$ of minimum degree such that $p(A) = J$, where A is the adjacency matrix and J is the matrix with every entry equal to 1.

hole: an induced subgraph that is isomorphic to the cycle C_k with $k \geq 4$.

homeomorphic graphs: two graphs that can both be obtained from the same graph by a sequence of edge subdivisions.

hypercube graph: a graph Q_d whose 2^d vertices can be labeled with the bitstrings of length d, so that two vertices are adjacent if and only if their labels differ in exactly one bit.

hypergraph: a finite set V of "vertices" together with a finite collection E of "edges" (sometimes, "hyperedges"), which are arbitrary subsets of V, written $H = (V, E)$.

icosahedral graph: the 1-skeleton of the icosahedron, which is a 3-dimensional polyhedron whose 20 faces are triangles; this graph has 12 vertices, each of degree 5, and 30 edges.

imbedding (of a graph in a surface): a drawing so that there are no edge-crossings; also *embedding*.

incidence matrix (of a digraph with no self-loops): the matrix M_I with $M_I[i,j] = 0$ if vertex v_i is not an endpoint of arc e_j, $M_I[i,j] = 1$ if v_i is the head of arc e_j, and $M_I[i,j] = -1$ if v_i is the tail of arc e_j.

incidence matrix (of a graph): the matrix M_I with $M_I[i,j] = 0$ if vertex v_i is not an endpoint of edge e_j, $M_I[i,j] = 1$ if e_j is a proper edge with endpoint v_i, and $M_I[i,j] = 2$ if e_j is a loop at v_i.

incidence matrix (of a hypergraph): for a hypergraph, the matrix $[m_{i,j}]$ where $m_{i,j} = 1$ if vertex x_j is in edge e_i, and $m_{i,j} = 0$ otherwise.

incidence rule: a rule specifying the endpoints of every edge of a graph.

incident edge (from [to] a digraph vertex): for a vertex u in a digraph, an arc e such that u is the tail [head] of e.

incident edge (in a graph): for a vertex u in a graph, an edge e such that u is an endpoint of e.

incident-edge table (for a graph): a table that lists, for each vertex, the edges having that vertex as an endpoint.

in-degree: for a vertex v, the number of arcs with head v.

independent set (in a graph): for a graph G, a subset of either $V(G)$ or $E(G)$ such that no two elements are adjacent in G.

independent set (of hypergraph vertices): a set of vertices that does not (completely) contain any edge of the hypergraph.

independence number (of a graph): the number $\alpha(G)$ of vertices in the largest independent subset in G.

independence number (of a hypergraph): the maximum number $\alpha(H)$ of vertices that form an independent set in H.

induced subgraph (on a vertex subset): the subgraph of a graph G containing every edge of G that joins two vertices of the prescribed vertex subset.

intersection graph (for a family of subsets): for a family $\mathcal{F} = \{S_j\}$ of sets, the graph with vertex set $\mathcal{F}$ such that there is an edge between each pair of subsets S_i and S_j whose intersection is nonempty.

intersection graph (of a hypergraph): for a hypergraph H, the simple graph $I(H)$ whose vertices are the edges of H, such that two vertices of $I(H)$ are adjacent if and only if the corresponding edges of H have nonempty intersection.

interval graph: the *intersection graph* of a family of subintervals of $[0,1]$.

invariant: a parameter or property of graphs that is preserved by isomorphisms.

irreducible tournament: a tournament with no bipartition V_1, V_2 of the vertices such that all arcs between V_1 and V_2 go from V_1 to V_2.

isolated point: a vertex of a graph that is not the endpoint of any edge.

isomorphic (pair of graphs): a pair of graphs with identical mathematical structure; formally, a pair of graphs such that there is an isomorphism from one to the other.

isomorphism (of digraphs): an isomorphism of the underlying graphs of two digraphs such that the edge-correspondence preserves direction.

isomorphism (of graphs): for graphs G and H, a pair of bijections $f_V \colon V_G \to V_H$ and $f_E \colon E_G \to E_H$ such that for every edge $e \in E_G$, the endpoints of e are mapped onto the endpoints of $f_E(e)$.

isomorphism (of simple graphs): a bijection between the vertices of two graphs such that a pair of vertices is adjacent in one graph if and only if the corresponding pair of vertices is adjacent in the other graph.

isomorphism type: for a graph [digraph] G, the class of all graphs [digraphs] isomorphic to G.

isoperimetric constant: for graph G with vertex set V_G, the minimum ratio $|\partial F|/|F|$ taken over all $F \subseteq V_G$ such that $0 < |F| \leq |V_G|/2$; denoted $h(G)$.

join: for graphs G and H, the graph $G * H$ obtained by adding to the disjoint union $G + H$ an edge from each vertex in G to each vertex in H.

k-connected: property of a graph G that the smallest size of a disconnecting set of vertices is at least k; that is, $\kappa(G) \geq k$.

k-cycle: a cycle of length k.

k-edge-connected: property of a graph G that $\kappa'(G) \geq k$.

k-partite graph: a graph whose vertex set can be partitioned into at most k parts in such a way that each edge joins different parts. Equivalent to a *k-colorable graph*.

k-regular: property of a graph or hypergraph that all its vertices have degree k.

king: a vertex in a digraph that can reach all other vertices by paths of length 1 or 2.

Kuratowski graphs: the complete graph K_5 and the complete bipartite graph $K_{3,3}$.

labeled graph: in applied graph theory, any graph in which the vertices and/or edges have been assigned labels; in pure graph theory, a graph in which standard labels $v_1, v_2, \ldots, v_n$ have been assigned to the vertices.

λ of a graph: for a connected d-regular graph, the maximum $|\lambda_i|$ taken over all eigenvalues λ_i that are not $\pm d$.

Laplacian (of a graph G): the matrix $D - A$ where D is the diagonal matrix with the degree sequence of G on the diagonal and where A is the adjacency matrix.

length (of a walk): the number of edge-steps in the sequence that specifies the walk.

lexicographic product: for graphs G and H, the graph $G \circ H$ that has vertex set $V_G \times V_H$ and edge set $\{(g,h)(g',h') \mid (gg' \in E_G),\ \text{or}\ (g = g'\ \text{and}\ hh' \in E_H)\}$.

line: synonym for edge, or refers to what is modeled by an edge.

line graph: for a graph G, the graph $L(G)$ whose vertices correspond to the edges of G, with two vertices being adjacent in $L(G)$ whenever the corresponding edges have a common endpoint in G.

linear extension ordering: a consecutive labeling $v_1, v_2, \ldots, v_n$ of the vertices of a digraph such that, if there is an arc from v_i to v_j, then $i < j$.

link: See *proper edge*.

loop (or ***self-loop***): an edge joining a vertex to itself.

magic graph: a connected graph whose edges can be labeled with distinct positive integers such that for each vertex v the sum of the labels of all edges incident with v is the same.

map: an imbedding of a graph on a surface.

map chromatic number: See *chromatic number of a map.*

map coloring: an assignment of colors to the regions of a map so that adjacent regions receive different colors.

matching: a set of pairwise disjoint edges in a graph or hypergraph.

matching number: in a graph, the maximum number of pairwise disjoint edges of the graph; in a hypergraph H, the maximum number $\nu(H)$ of pairwise disjoint edges of H; that is, the cardinality of the largest partial of H that forms a matching.

minor: for a graph G, any graph that can be obtained from G by a sequence of edge deletions and contractions.

Möbius band: the surface obtained from a rectangular sheet by pasting the left side to the right with a half-twist.

multi-arc: two or more arcs, all of which have the same head and the same tail.

multi-edge: a set of at least two edges, all of which have the same endpoints.

multigraph: a graph with multi-edges.

neighbor: for a vertex, any vertex adjacent to it.

node: a vertex, or refers to what is modeled by a vertex.

nonorientable surface: a surface such that some subportion forms a Möbius band.

nonorientable surface of crosscap number k: the surface N_k obtained by adding k crosscaps to a sphere.

nonplanar: property of a graph that it cannot be drawn in the plane without crossings.

nonseparable: property of a connected graph that it has no cut-vertex.

normal: property of a hypergraph H that $q(H) = \Delta(H)$.

normalized drawing: the usual way a graph is drawn, avoiding pathological contrivances such as overloaded crossings (i.e., more than two edges).

null graph: (usually) a graph with no vertices or edges.

obstruction to n-coloring: synonym for a chromatically $(n+1)$-critical graph, since a chromatically $(n+1)$-critical subgraph prevents n-chromaticity.

octahedral graph: the 1-skeleton of the 3-dimensional octahedron, or sometimes, a generalization of this graph.

1-skeleton (of a polyhedron): the graph whose vertices and edges are, respectively, the vertices and edges of that polyhedron.

open: property of a walk, trail, or path that its final vertex is different from its initial vertex.

order (of a graph): for a graph G, the cardinality $|V_G|$ of the vertex set.

order (of a hypergraph edge): the number of vertices in the edge.

orientable surface: any surface obtainable from a sphere by adding handles.

orientable surface of genus g: the surface S_g obtained by attaching g handles to a sphere.

orientation: an assignment of a direction to every edge of a graph, making it a digraph.

origin (of a walk): the initial vertex of the walk.

out-degree: for a vertex v, the number of arcs with tail v.

partial: for a hypergraph $H=(V,E)$, a hypergraph $H'=(V,E')$ such that $E'\subseteq E$.

path: a trail in which all of its vertices are different, except that the initial and final vertices may be the same. See also *u,v-path*.

path, ***directed***: a directed trail in which no vertex is repeated.

pebbling number (of a graph): the maximum value $\pi(G)$ of the rooted pebbling number over all roots of the graph G.

pebbling step from u ***to*** v: for an edge uv, the removal of two pebbles from u and placement of one pebble on v.

perfect graph: a graph such that every induced subgraph has vertex chromatic number equal to its clique number.

perfect matching (or ***1-factor***): a matching that covers all the vertices of a graph.

Petersen graph: a 3-regular 10-vertex graph that looks like a 5-cycle joined by its vertices to the vertices of a 5-pointed star drawn in its interior.

planar: property of a graph that it can be drawn in the plane without crossings.

Platonic graph: the 1-skeleton of a Platonic solid.

Platonic solid: any of five 3-dimensional polyhedra whose sides are all identical regular polygons.

polyhedron: a generalization of a polygon to higher dimensions; usually a solid 3-dimensional figure subtended by planes.

proper edge (or ***link***): an edge with two distinct endpoints.

pseudograph: synonym for a graph with loops.

r-partite hypergraph: an r-uniform hypergraph whose vertex set can be partitioned into r blocks so that each edge intersects each block in exactly one vertex.

r-uniform: property of a uniform hypergraph that r is the common edge-order.

radius: for a connected graph G, the minimum eccentricity among the vertices of G.

Ramanujan graph: A d-regular graph G such that $\lambda(G) \leq 2\sqrt{d-1}$.

Ramsey number, classical: the number $r(m, n)$, which is the smallest positive integer k such that every simple graph with k vertices either contains K_m as a subgraph or has a set of n independent vertices.

Ramsey number: the number $R(G, H)$, which is the smallest positive integer k such that, if the edges of K_k are bipartitioned into red and blue classes, then either the red subgraph contains a copy of G or the blue subgraph contains a copy of H.

random graph on n vertices: an n-vertex graph generated by a probability distribution, in which each edge is as likely to occur as any of the others.

reachable vertex (from vertex u): a vertex v such that there is a u, v-path.

reconstructible: property of a graph that it is uniquely determined by its collection of vertex-deleted subgraphs.

reconstructible invariant: an invariant that is uniquely determined by the collection of vertex-deleted subgraphs of a graph.

reducible: property of a digraph that its vertex set can be partitioned into a disjoint union $V_1 \cup V_2$ so that all arcs joining V_1 and V_2 go from V_1 to V_2.

region: for a graph imbedded in a surface, a maximal expanse of surface containing no vertex and no part of any edge of the graph.

regular: property of a graph or hypergraph that all its vertices have the same degree. See also *k-regular*.

representation (of a graph): a graph description, such as a drawing, from which a formal specification can be constructed and labeled with the vertex names and edge names, so as to obtain a graph that conforms to the incidence rule for the graph.

rooted pebbling number (of a graph): for a connected graph with root vertex r, the minimum number t so that from every starting configuration of t pebbles it is possible to move a pebble to r via pebbling steps.

rotation system (of an imbedding): a list of the cyclic orderings of the incidence of edges at each vertex.

Schreier graph: a graph that depicts the cosets of some subgroup of a group with some set of generators; the vertices represent cosets, and the edges (often "color-coded" for the generators) represent the product rule.

self-complementary: property of a graph that it is isomorphic to its complement.

self-loop: an edge that joins a vertex to itself; see *loop*.

simple digraph: a digraph that has no self-loops and no pair of arcs with the same tail and head.

simple graph: a graph with no loops or multi-edges.

simple hypergraph: a hypergraph with no repeated edges.

sink: a digraph vertex with out-degree zero.

source: a digraph vertex with in-degree zero.

spanning subgraph: a subgraph of a graph G that includes all vertices of G.

specification (of a graph): a list of its vertices and a list of its edges, with the incidence rule for determining the endpoints of every edge.

spectrum (of a graph): the multiset of its eigenvalues.

strong component: in a digraph, a maximal subdigraph that is strongly connected.

strong orientation: for a graph, an assignment of a direction to every edge making it a strongly connected digraph.

strong product: for graphs G and H, the graph $G \boxtimes H$ that has vertex set $V_G \times V_H$ and edge set $\big\{(g',h)(g',h') \mid (g = g' \text{ or } gg' \in E_G) \text{ and } (h = h' \text{ or } hh' \in E_H)\big\}$.

strong tournament: a tournament in which there is a directed path from every vertex to every other vertex.

strongly connected: property of a digraph that every vertex is reachable from every other vertex.

strongly regular graph (with parameters $(n,\, k,\, r,\, s)$): an n-vertex, k-regular graph in which every adjacent pair of vertices is mutually adjacent to r other vertices, and in which every pair of nonadjacent vertices is mutually adjacent to s other vertices.

subdivision (of an edge): the operation of inserting a new vertex into the interior of the edge, thereby splitting it into two edges.

subdivision: given a graph, any new graph obtained by subdividing one or more edges one or more times.

subgraph: given a graph G, a graph whose vertices and edges are all in G.

supermagic graph: a connected graph whose edges can be labeled with consecutive positive integers such that for each vertex v the sum of the labels of all edges incident with v is the same for all v.

tail (of an arc): the vertex the arc goes from.

terminus (of a walk): the last vertex of the walk.

tetrahedral graph: another name for the complete graph K_4, resulting from the fact that it is equivalent to the 1-skeleton of the 4-sided Platonic solid called a tetrahedron.

thickness: for a graph G, the minimum number $\theta(G)$ of planar subgraphs whose union is G.

topological sort (or ***topsort***): an algorithm that assigns a linear extension ordering to a DAG.

tough graph: a connected graph G such that for every nonempty set S of vertices, the number of components of the graph $G - S$ does not exceed $|S|$.

total dominating set (of a graph): a set S of vertices such that every vertex is adjacent to a vertex in S.

total domination number: the minimum cardinality $\gamma_t(G)$ of a total dominating set in graph G.

tournament: a digraph with exactly one arc between each pair of distinct vertices.

trail: a walk in which no edge occurs more than once.

trail, ***directed***: a directed walk in which no arc is repeated.

transitive: property of a digraph that whenever it contains an arc from u to v and an arc from v to w, it also contains an arc from u to w.

transitive orientation: for a graph, an assignment of a direction to every edge, making it a transitive digraph.

transmitter: in a digraph, a vertex that has an arc to every other vertex.

transversal: in a hypergraph, a set of vertices that has nonempty intersection with every edge of the hypergraph.

transversal number: the minimum number $\tau(H)$ of vertices taken over all transversals of H.

tree: a connected graph without a cycle.

trivial graph: the graph with one vertex and no edge.

Turán graph: the n-vertex k-partite simple graph $T_k(n)$ with the maximum number of edges.

u,v-path: a path whose origin is the vertex u and whose terminus is the vertex v.

underlying graph: for a digraph, the graph obtained from the digraph by stripping the directions off all the arcs.

uniform: property of a hypergraph that all edges have the same number of vertices. See also *r-uniform.*

unilaterally connected (or ***unilateral***): property of a digraph that for every pair of vertices u, v, there is either a uv-path or a vu-path.

upset: a simple hypergraph in which every superset of every edge is also an edge of the hypergraph.

valence: a synonym for *degree* (adapted from molecular bonds in chemistry).

vertex: a point; an element of the first constituent set of a graph.

vertex coloring: an assignment of colors to the vertices of a graph so that adjacent vertices receive different colors.

(***vertex***) ***connectivity***: the smallest number $\kappa(G)$ of vertices whose removal disconnects the graph; by convention, $\kappa(K_n) = n - 1$.

vertex cut: See *disconnecting set.*

vertex-deleted subgraph: any subgraph obtained from a graph by removing a single vertex and all of its incident edges.

vertex invariant: a property at a vertex that is preserved by every isomorphism.

walk: an alternating sequence $v_0, e_1, v_1, \ldots, e_r, v_r$ of vertices and edges where consecutive edges are adjacent, so that each edge e_i joins vertices v_{i-1} and v_i.

walk, ***directed***: an alternating sequence of vertices and arcs $v_0, e_1, v_1, e_2, \ldots, e_n, v_n$ where the arcs align head to tail, so that each vertex is the head of the preceding arc and the tail of the subsequent arc.

weakly connected (or ***weak***) ***digraph***: a digraph whose underlying graph is connected.

weighted graph: a graph model in which each edge is assigned a number called the weight or the cost.

wheel graph: an $(n + 1)$-vertex graph W_n that “looks like” a wheel whose rim is an n-cycle and whose hub vertex is joined by spokes to all the vertices on the rim.

8.1 INTRODUCTION TO GRAPHS

Graphs are highly adaptable mathematical structures, and can be represented on a computer so that as new applications arise, existing algorithms can be reused without rewriting. This section provides some of the basic terminology and operations needed for the study of graphs and describes several useful families of graphs.

8.1.1 VARIETIES OF GRAPHS AND GRAPH MODELS

Due to the vast breadth of the usefulness of graphs, the terminology varies widely, not only from one type of graph to another, but also from one application to another. The table in Fact 1 gives synonyms for several terms. Definitions for undirected graphs are given first, followed by definitions for directed graphs. Because much of the terminology is similar for the two types of graph, only terms that are different for directed graphs are given.

Definitions:

A ***graph*** $G = (V, E)$ is a set V of *vertices* and a set E of *edges* (both sets are finite and V is nonempty unless specified otherwise) such that each edge is associated with either two vertices or one vertex twice. It is sometimes denoted (V_G, E_G) or $(V(G), E(G))$.

A ***vertex*** is usually conceptualized as a point. Abstractly, it is a member of the first of the two sets that form a *graph*.

An ***edge*** is usually conceptualized as a line segment or curve, either joining one vertex to another or joining a vertex to itself. Abstractly, it is a member of the second of the two sets that form a *graph*.

The number of vertices of a graph is often called its ***order***. The number of edges of a graph is sometimes called its ***size***.

A ***proper edge*** (or ***link***) is an edge that joins one vertex to another.

A ***loop*** (or ***self-loop***) is an edge that joins a vertex to itself.

The ***endpoints*** of an edge are the vertices that the edge joins. A loop has only one endpoint.

An edge e is ***incident with*** a vertex v if v is an endpoint of e.

An ***incidence rule*** specifies the endpoints of the edges.

A ***simple graph*** is a graph G that has no loops and in which no two edges have the same endpoints. In a simple graph, an edge with endpoints v and w can be regarded as the pair $\{v, w\}$ and is often denoted simply as vw.

A graph with no edges is called a ***null graph***. If further, V is empty, then the result is the ***empty graph***. (Note that some researchers invert the meanings of null graph and empty graph.)

The ***trivial graph*** has just one vertex and no edges.

Vertices v and w are ***adjacent*** if there is an edge whose endpoints are v and w.

Two edges are ***adjacent*** if they have a common endpoint.

A ***neighbor*** of a vertex is any vertex to which it is adjacent.

An ***attribute*** of the edge set or vertex set of a graph is a feature such as length, cost, or color sometimes attached to graphs.

A ***graph model*** is a graph which may have attributes on its edges or vertices. The vertices and edges of the model may represent arbitrary objects and relationships from the context of the application.

A ***weighted graph*** is a graph in which each edge is assigned a number called the weight or cost.

A ***node*** is sometimes a synonym for a vertex and sometimes refers to whatever is modeled by a vertex in a graph model.

A ***line*** is sometimes a synonym for an edge and sometimes refers to whatever is modeled by an edge in a graph model.

If at least two edges have the same endpoints, the set of all edges with these endpoints is called a ***multi-edge***. If r is the number of these edges, this is a sometimes called an ***edge of multiplicity*** r. A graph with a multi-edge is sometimes said to have ***multiple edges*** or ***parallel edges***.

A ***multigraph*** is another name for a graph with multi-edges but no loops, used for emphasis when the context is largely restricted to simple graphs.

A ***pseudograph*** (or ***general graph***) is another name for a graph in which loops and multi-edges are permitted, used for emphasis when the context is largely restricted to loop-free graphs.

The ***degree*** of vertex v, $\deg(v)$, is the number of proper edges plus *twice* the number of loops incident with v. Thus, in a drawing, it is the number of edge-endings at v.

The ***valence*** of a vertex is a synonym for *degree* adapted from terminology in chemistry.

A vertex of degree 0 is called an ***isolated vertex***.

A vertex of degree 1 is called a ***leaf*** or an ***end vertex***.

A ***regular*** graph is a graph in which all vertices have the same degree. It is called ***k-regular*** if that degree is k.

The ***degree sequence*** of a graph is the sequence of the degrees of its vertices, usually given in increasing or decreasing order.

A ***graphical sequence*** is a sequence of nonnegative integers that is the degree sequence of some simple graph.

A ***digraph*** or ***directed graph*** $D = (V, A)$ is a set V of *vertices* and a set A of *arcs* (both sets are finite and V is nonempty unless specified otherwise) such that each arc is associated with an ordered pair of vertices (which may be the same). It is sometimes denoted (V_D, A_D) or $(V(D), A(D))$.

A ***direction*** on an edge is an ordering for its endpoints so that the edge goes *from* one endpoint and *to* the other. Any edge, including a loop, can be directed by giving it a sense of forward progression; for example, in a graph drawing, by placing an arrow on the edge.

An ***arc*** is a directed edge.

The ***tail*** of an arc is the vertex at which the arc originates. The ***head*** is the vertex at which the arc terminates.

Two arcs are ***parallel*** if they have the same head and the same tail. They are ***opposite*** if the tail of each is the head of the other.

A ***strict digraph*** has no parallel arcs. In set theory terms, it is the graph of a relation.

A ***simple digraph*** has no loops and no parallel arcs. In set theory terms, it is the graph of an irreflexive relation.

The ***out-degree*** of vertex v, denoted $\mathrm{od}(v)$ or $\deg^{+}(v)$, is the number of arcs having v as tail. The ***in-degree*** of vertex v, denoted $\mathrm{id}(v)$ or $\deg^{-}(v)$, is the number of arcs having v as head.

A vertex with in-degree 0 and positive out-degree is called a ***source*** or ***transmitter***. A vertex with out-degree 0 and positive in-degree is called a ***sink*** or ***receiver***.

The ***degree pair*** of vertex v is the ordered pair $(\mathrm{od}(v), \mathrm{id}(v))$.

The ***degree sequence*** of a digraph is the sequence of the degree pairs of its vertices, usually given in increasing or decreasing order of the out-degree.

A ***digraphical sequence*** is a sequence of ordered pairs of nonnegative integers that is the degree sequence of some simple digraph.

Facts:

1. The following table lists some graph theory synonyms.

vertex: point, node
edge: line, link
loop: self-loop
neighbor: adjacent vertex
arc: directed edge
degree: valence
number of vertices: order
number of edges: size
nonsimple graph: pseudograph, general graph
loop-free nonsimple graph: multigraph

2. The following table lists some of the varieties of graphs and digraphs.

graph variety	*loops allowed?*	*multi-edges allowed?*
simple graph	NO	NO
multigraph	NO	YES
general graph	YES	YES
pseudograph	YES	YES
digraph	YES	YES
strict digraph	YES	NO*
simple digraph	NO	NO*

*at most one arc in each direction between two vertices

3. In a drawing of a graph, the degree of a vertex v equals the number of edge-ends at v. The degree of v need *not* equal the number of edges at v, since each loop contributes twice toward the degree.

4. In every graph, the sum of the degrees equals twice the number of edges. From this it follows that the sum of the degrees of all vertices is even.

5. In every graph the number of vertices of odd degree is even.

6. The name *handshaking lemma* is commonly applied to various elementary results about the degrees of simple graphs, especially Facts 4 and 5.

7. In every simple graph with at least two vertices, there is a pair of vertices with the same degree.

8. *Havel's theorem*: A sequence of nonnegative integers is graphical if and only if the sequence obtained by deleting the largest entry d and subtracting 1 from each of the d next largest entries is graphical. (V. Havel, 1955)

9. A nonincreasing sequence of nonnegative integers $d_1, d_2, \ldots, d_n$ is graphical if and only if its sum is even, and for $k = 1, 2, \ldots, n$,

$$\sum_{i=1}^{k} d_i \;\le\; k(k-1) + \sum_{i=k+1}^{n} \min\{k, d_i\}.$$

(P. Erdős and T. Gallai, 1960)

10. In every digraph, the sum of the in-degrees equals the sum of the out-degrees, and this is equal to the number of arcs.

11. A sequence of ordered pairs of nonnegative integers is digraphical if and only if the sequence obtained by replacing the largest first entry d by 0 and subtracting 1 from each of the d largest second entries among the other pairs is digraphical.

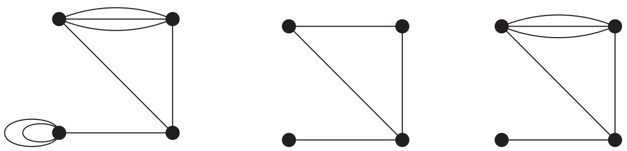
12. A sequence of ordered pairs of nonnegative integers at most $n-1$, say $(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)$, with the a_i nonincreasing is digraphical if and only if $\sum_{i=1}^{n} a_i = \sum_{i=1}^{n} b_i$, and for $k = 1, 2, \ldots, n$,

$$\sum_{i=1}^{k} a_i \;\le\; \sum_{i=1}^{k} \min\{k-1, b_i\} + \sum_{i=k+1}^{n} \min\{k, b_i\}.$$

(D. L. Fulkerson, 1960)

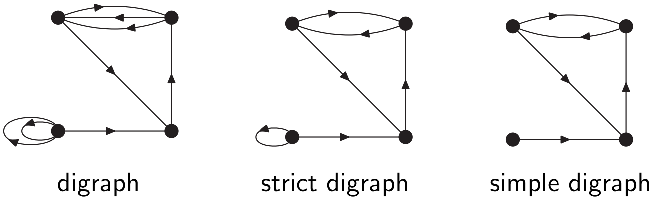
Examples:

1. The following figure gives examples of the various varieties of graphs. (See the table in Fact 2.)

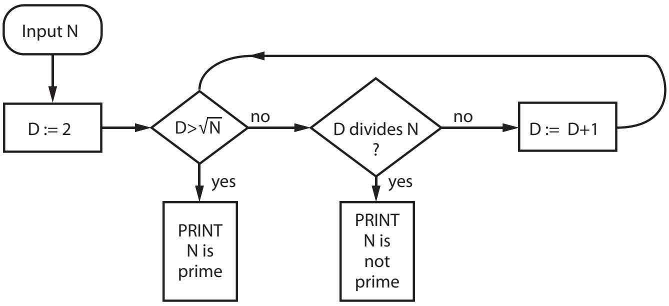


graph/pseudograph simple graph multigraph

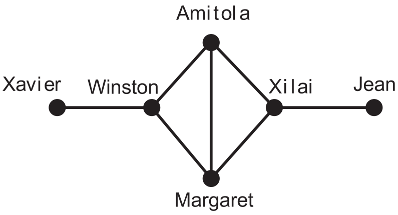
2. The following figure gives examples of the various varieties of digraphs. (See the table in Fact 2.)



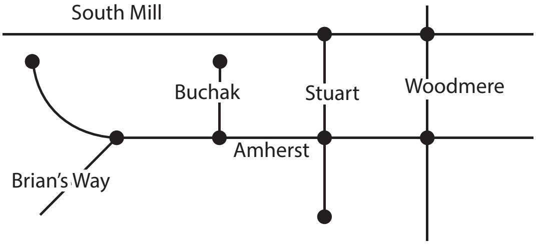
3. *Computer programming flowchart* (always a digraph): Each vertex represents some programmed operation or decision, and each arc represents the flow of control to the next operation or decision.



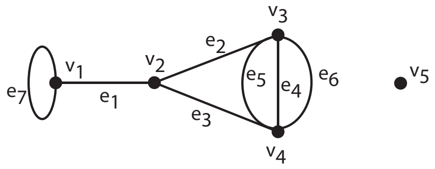
4. *Model for social networks*: Each vertex represents a person in the network, and each edge represents a form of interaction between the persons represented by its endpoints. This is illustrated by the following graph.



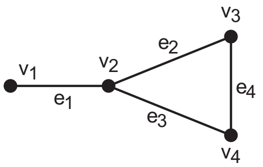
5. *Model for road networks* (most edges undirected): Each vertex represents either an intersection of two roads or the end of a dead-end street. The absence of an endpoint in the illustration indicates that the road continues beyond what is shown. Direction on an edge may be used to indicate a one-way road, with undirected edges being two-way roads.



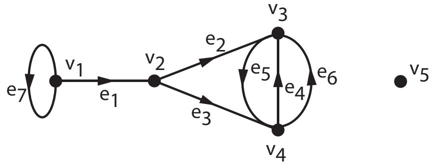
6. In the following graph with vertex set $V = \{v_1, v_2, v_3, v_4, v_5\}$ and edge set $E = \{e_1, e_2, e_3, e_4, e_5, e_6, e_7\}$, the vertex v_5 is an isolated vertex, and the degree sequence is (0, 3, 3, 4, 4). The edge e_7 is a loop, and the three edges e_4, e_5, and e_6 form a multi-edge.



7. Deleting the isolated vertex and the self-loop in Example 6 and then reducing the multi-edge to a single edge yields the following simple graph, whose degree sequence is $(1, 2, 2, 3)$.



8. One possible choice of edge directions for the graph of Example 6 yields this digraph.



9. The sequence $(1, 2, 2, 3, 4, 5)$ is not graphical, by Fact 4, because its sum is odd.

10. Havel's reduction (Fact 8) of the sequence $(2, 2, 2, 3, 4, 5)$ is $(1, 1, 1, 2, 3)$. Havel's reduction of that sequence is $(0, 0, 1, 1)$. Since $(0, 0, 1, 1)$ is the degree sequence of a graph with four vertices, two of which are isolated and two of which are joined by an edge, it follows from Havel's theorem that the sequence $(2, 2, 2, 3, 4, 5)$ is graphical.

11. The sequence $(2, 1), (2, 0), (1, 1), (1, 3)$, is not digraphical since the sum of the first entries does not equal the sum of the second entries.

12. The reduction of the sequence $(3, 1), (1, 2), (1, 2), (1, 1)$ using Fact 11 is the sequence $(0, 1), (1, 1), (1, 1), (1, 0)$. Since the second sequence is digraphical, being the degree sequence of the directed path of length 3, the first sequence is also digraphical.

8.1.2 GRAPH OPERATIONS

Definitions:

A graph $H = (V_H, E_H)$ is a ***subgraph*** of a graph $G = (V_G, E_G)$ if its vertex set and edge set are subsets of V_G and E_G, respectively.

A ***spanning subgraph*** of a graph G is a subgraph that contains all the vertices of G.

The ***induced subgraph*** on a nonempty set S of vertices in a graph G is the subgraph whose vertex set is S and whose edge set consists of all edges of G having both endpoints in S. It may be denoted by $\langle S \rangle$ or $G[S]$ and is the maximal subgraph of G with vertex set S.

An ***induced subgraph*** of G is a subgraph H such that every edge of G that joins two vertices of H is also an edge of H.

Deleting an edge e from a graph G results in the subgraph $G - e$ that contains all the vertices of G and all the edges of G except for e.

Deleting a set Y ***of edges*** from a graph G results in the subgraph $G - Y$ that contains all the vertices of G and all the edges of G except for those in Y.

Deleting a vertex v from a graph G results in the subgraph $G - v$ that contains all the vertices of G except v and all the edges of G except those incident with v. It is the induced subgraph $\langle V_G - \{v\} \rangle$.

Deleting a set S ***of vertices*** from a graph G results in the subgraph $G - S$ that contains all the vertices of G except those in S and all the edges of G except those incident with vertices in S. It is the induced subgraph $\langle V_G - S \rangle$.

Contracting an edge e in a graph G means shrinking the edge to a point, so that its endpoints are merged, without changing the rest of the graph. The resulting graph is denoted G/e (or $G \cdot e$ or $G \downarrow e$). To construct G/e from G, delete the edge e from the edge set and replace all instances of its endpoints in the vertex set and incidence rule by a new vertex.

A ***minor*** of a graph G is any graph that can be obtained from G by a sequence of edge deletions and contractions and vertex deletions.

The ***graph union*** $G \cup H$ has as its vertices and edges those vertices and edges that are in G or H.

The ***graph intersection*** $G \cap H$ has as its vertices and edges those vertices and edges that are both in G and in H.

The ***graph sum*** (or ***disjoint union***) $G + H$ consists of the disjoint unions of the vertex sets and of the edge sets of the graphs G and H.

The ***iterated graph sum*** nG is the sum of n disjoint copies of G.

The ***join*** $G * H$ is obtained by adding to $G + H$ an edge from each vertex in G to each vertex in H.

The ***Cartesian product*** $G \square H$ (or sometimes $G \times H$) has as its vertices the product $V_G \times V_H$ and as its edges $(V_G \times E_H) \cup (E_G \times V_H)$. The endpoints of the edge (u, d) are the vertices (u, x) and (u, y), where x and y are the endpoints of d in H, and those of the edge (e, w) are (u, w) and (v, w), where u and v are the endpoints of e.

An ***isomorphism*** $f\colon G \to H$ (of graphs) establishes their structural equivalence. It is given by a pair of bijections $f_V\colon V_G \to V_H$ and $f_E\colon E_G \to E_H$ such that if u and v are the endpoints of edge e in graph G, then $f_V(u)$ and $f_V(v)$ are the endpoints of $f_E(e)$ in graph H. The vertex function and the edge function can both be denoted f without the subscript. (See §8.5.)

Two graphs are ***isomorphic*** if there is an isomorphism between them. This means that they are essentially the same graph except for the names of their vertices and edges.

A ***graph mapping*** $f\colon G \to H$ (of graphs) is a pair of functions $f_V\colon V_G \to V_H$ and $f_E\colon E_G \to E_H$ such that if u and v are the endpoints of edge e in G, then $f(u)$ and $f(v)$ are the endpoints of $f(e)$ in H. Such a pair of functions is said to *preserve incidence.* The vertex function and the edge function can both be denoted f without the subscript.

An ***automorphism*** of a graph G is an isomorphism of G to itself.

The ***automorphism group*** $\mathcal{A}ut(G)$ is the group of all automorphisms of graph G.

Subdividing an edge e is the operation of inserting a new vertex in the interior of an edge. Combinatorially, this is achieved by deleting e and adding a new vertex adjacent to the endpoints of e.

Two graphs are ***homeomorphic*** if there is a graph from which they can both be obtained by a sequence of edge subdivisions.

The ***complement*** $\overline{G}$ of a simple graph G has the same vertex set as G, with two vertices being adjacent in $\overline{G}$ if and only if they are not adjacent in G.

A ***self-complementary*** graph is a graph that is isomorphic to its complement.

The ***line graph*** $L(G)$ of a graph G has vertices corresponding to the edges of G, with two vertices in $L(G)$ being adjacent whenever the corresponding edges are adjacent in G.

Facts:

1. If a graph J is isomorphic to a subgraph of a graph G, then it is commonly said that J "is" a subgraph of G, even though V_J and E_J might not be subsets of V_G and E_G.

2. A graph is a subgraph of its union with any other graph.

3. The intersection of two graphs is a subgraph of each of them.

4. A graph mapping is the combinatorial counterpart of what is topologically a continuous function from one graph to the other.

5. A graph isomorphism is a graph mapping for which both the vertex function and the edge function are bijections.

6. There is a self-complementary graph of order n if and only if $n \equiv 0$ or $1 \pmod 4$.

7. The automorphism group $\mathcal{A}ut(G)$ of any simple graph is isomorphic to the automorphism group $\mathcal{A}ut(\overline{G})$ of its complement.

8. A connected graph G is isomorphic to its line graph if and only if G is a cycle (§8.1.3).

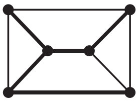
9. If two connected graphs have isomorphic line graphs, then either they are isomorphic to each other or they are K_3 and $K_{1,3}$ (see §8.1.3).

10. $\mathcal{A}ut(K_n)$ is isomorphic to the symmetric group S_n (see §5.3.1).

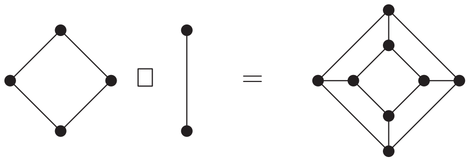
11. $\mathcal{A}ut(C_n)$ is isomorphic to the dihedral group D_n (see §5.3.2).

Examples:

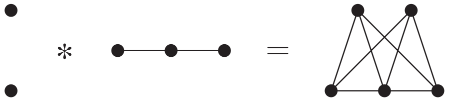
1. The dark subgraph spans the following graph, because it contains every vertex of the given graph.



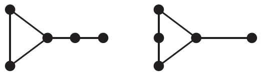
2. The Cartesian product $C_4 \,\Box\, K_2$ (see §8.1.3) is illustrated as follows:



3. The join $\overline{K_2} * P_3$ (see §8.1.3) is illustrated as follows:



4. The following two graphs are homeomorphic, but not isomorphic.



5. The graphs $K_{3,3}$ and $2K_3$ (see §8.1.3) are complements of each other.

6. The path P_4 and the cycle C_5 (see §8.1.3) are self-complementary.

7. The line graph $L(K_4)$ (see §8.1.3) is isomorphic to the octahedral graph $K_{2,2,2}$.

8.1.3 SPECIAL GRAPHS AND GRAPH FAMILIES

Definitions:

Note: Many of the following graphs are drawn in Figures 1 and 2.

The ***bouquet*** B_n is the graph with one vertex and n loops.

The ***dipole*** D_n is the graph with two vertices and an edge of multiplicity n joining them.

The ***complete graph*** K_n is the simple graph with n vertices in which every pair of vertices is adjacent.

The ***n-path*** P_n consists of a sequence of n vertices $v_1, v_2 \ldots, v_n$ and the $n-1$ edges joining successive vertices in the sequence; that is, the $n-1$ edges are $v_1v_2, v_2v_3, \ldots, v_{n-1}v_n$.

A ***path*** is a graph that is an n-path for some $n \geq 1$.

The ***n-cycle*** C_n consists of a sequence of n vertices $v_1, v_2, \ldots, v_n$ and the n edges joining successive vertices cyclically; that is, the n edges are $v_1v_2, v_2v_3, \ldots, v_{n-1}v_n, v_nv_1$.

A ***cycle*** is a graph which is an n-cycle for some $n > 0$.

The ***n-wheel*** W_n is the join of K_1 and the n-cycle C_n.

A graph is ***bipartite*** if its vertices can be partitioned into two subsets (the ***parts***, or ***partite sets***) so that no two vertices in the same part are adjacent.

The ***complete bipartite graph*** $K_{r,s}$ is the simple bipartite graph in which the two parts have cardinalities r and s, such that every vertex in one part is adjacent to every vertex in the other part.

The ***complete r-partite graph*** $K_{n_1,n_2,\ldots,n_r}$ has r disjoint subsets of vertices of orders $n_1, n_2, \ldots, n_r$, with two vertices adjacent if and only if they lie in different subsets. If the r sets all have t vertices, this graph is sometimes denoted $K_{r(t)}$.

A graph G is ***connected*** if for each pair of vertices in G, there is a path in G from one to the other.

A ***tree*** is a connected graph without any cycles as subgraphs. (See Chapter 9.) A ***forest*** is a graph without any cycles as subgraphs.

The ***Kuratowski graphs*** are the graphs K_5 and $K_{3,3}$.

The ***Petersen graph*** is the graph constructed from two disjoint 5-cycles on the vertices v_1, v_2, v_3, v_4, v_5 and w_1, w_2, w_3, w_4, w_5 by adding the edges $v_1w_2, v_2w_4, v_3w_1, v_4w_3, v_5w_5$. (See Figure 2.)

A ***Platonic solid*** is a regular 3-dimensional polyhedron.

The ***1-skeleton*** of a polyhedron is the graph that has as its vertices and edges those of the polyhedron.

The ***tetrahedral graph*** is the 1-skeleton of the 4-sided Platonic solid called a tetrahedron (its faces are triangles). It has 4 vertices, each of degree 3, and 6 edges.

The ***cube graph*** Q_3 is the 1-skeleton of the 6-sided Platonic solid called a cube (its faces are squares). It has 8 vertices, each of degree 3, and 12 edges.

The ***d-dimensional hypercube*** graph Q_d is a graph with 2^d vertices that can be labeled with the 2^d bitstrings of length d so that two vertices are adjacent if and only if their labels differ in exactly one bit.

The ***octahedral graph*** $\mathcal{O}_3$ is the 1-skeleton of the 8-sided Platonic solid called an octahedron (its faces are triangles). It has 6 vertices, each of degree 4, and 12 edges.

The ***generalized octahedral graph*** $\mathcal{O}_n$ is the graph that can be obtained from the complete graph K_{2n} by removing n mutually nonadjacent edges. It is isomorphic to $K_{n(2)}$.

The ***dodecahedral graph*** is the 1-skeleton of the 12-sided Platonic solid called a dodecahedron (its faces are pentagons). It has 20 vertices, each of degree 3, and 30 edges.

The ***icosahedral graph*** is the 1-skeleton of the 20-sided Platonic solid called an icosahedron (its faces are triangles). It has 12 vertices, each of degree 5, and 30 edges.

The ***intersection graph*** of a finite collection $F = \{S_1, S_2, \ldots, S_k\}$ of subsets of some set has as its vertices the subsets themselves, with an edge between each pair of subsets whose intersection is nonempty.

An ***interval graph*** is any graph isomorphic to the intersection graph of some collection of intervals on the real line.

Facts:

1. In a computer program, the trivial graph is often used as the initial value of a graph-valued variable, similar to how an integer-valued variable is initialized to zero. As the program runs, the graph-valued variable can be modified by adding vertices and edges.

2. Bouquets and dipoles are fundamental building blocks for graphs constructed by topological techniques.

3. Every path is a tree.

4. A graph is bipartite if and only if it has no cycles of odd length.

5. Every tree is bipartite.

6. The hypercube graphs Q_n can be defined recursively as follows: $Q_0 = K_1$, $Q_n = K_2 \,\Box\, Q_{n-1}$ for $n > 0$.

7. The hypercube graph Q_n is bipartite and is isomorphic to the lattice of subsets of a set of n elements. (See §5.7.1.)

8. The octahedral graphs $\mathcal{O}_n$ can be defined recursively as follows: $\mathcal{O}_0 = \overline{K_2}$, $\mathcal{O}_n = \overline{K_2} * \mathcal{O}_{n-1}$ for $n > 0$.

9. There are exactly five Platonic graphs: the tetrahedral graph K_4, the cube Q_3, the octahedral graph $\mathcal{O}_3$, the dodecahedral graph, and the icosahedral graph.

Examples:

1. Figure 1 shows some of the classes of graphs that occur most often in general constructions.

2. Figure 2 shows some of the graphs that occur most often as special examples.

8.1.4 GRAPH REPRESENTATION AND COMPUTATION

To apply a computer to graph-theoretic computations, it is necessary to specify the underlying graph completely and without ambiguity. The representations are also useful in their own right.

Definitions:

A ***specification*** of a graph is a list of its vertices, a list of its edges, and the incidence rule for determining the endpoints of every edge.

An ***endpoint table*** for a graph is a tabular description of the incidence rule, that gives the endpoints of every edge. In a digraph or partially directed graph, the tail and head of each arc are distinguished.

An ***incident-edge table*** for a graph is a tabular description of the incidence rule, that gives for each vertex v, a list of the edges having v as an endpoint. If the graph is directed, this list is partitioned into two sublists, according to whether v is tail or head.

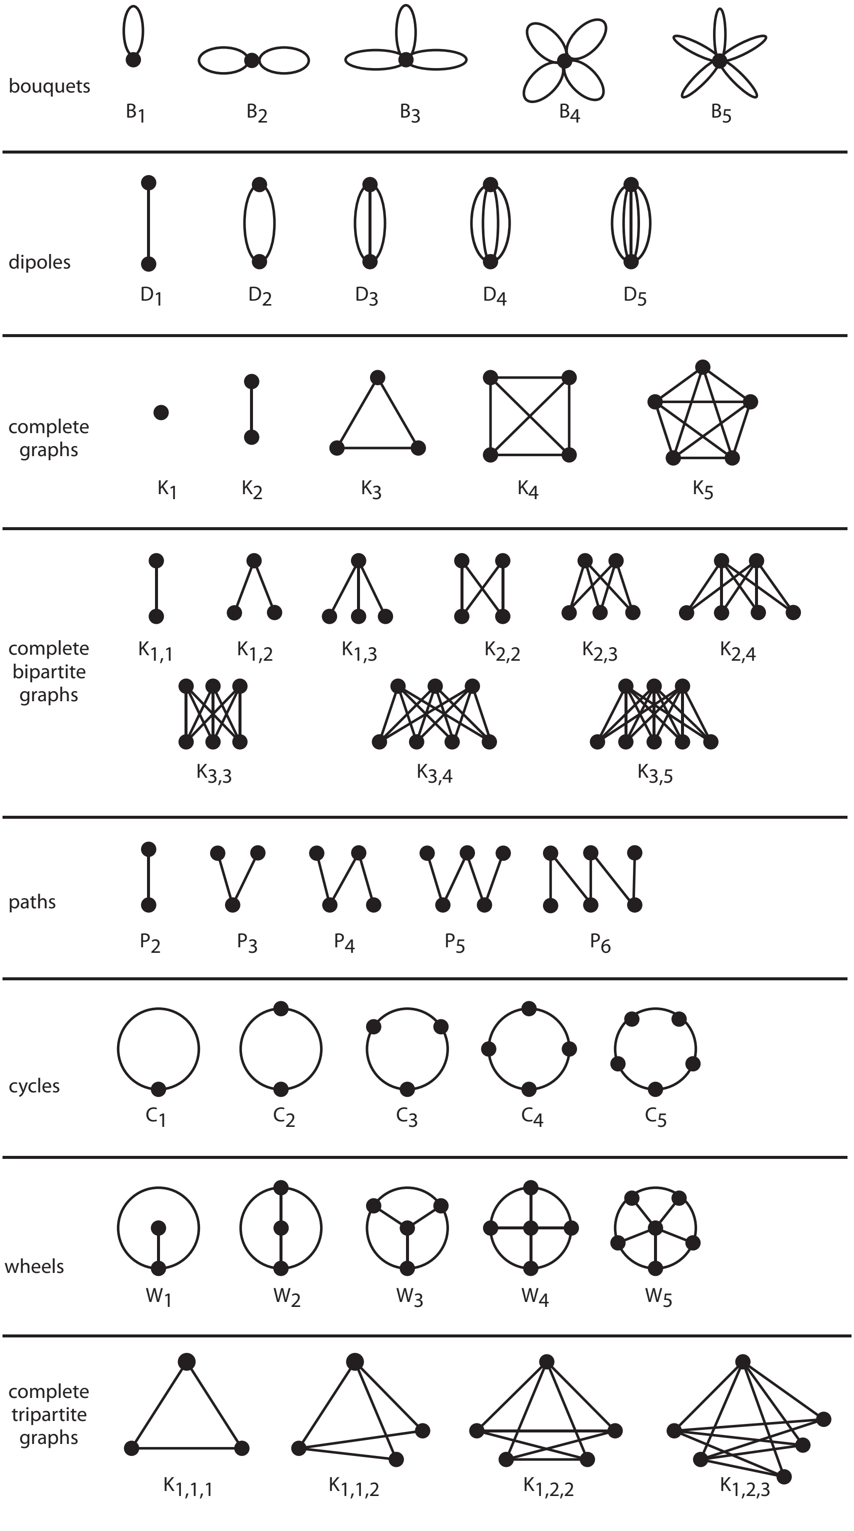
A ***representation*** of a graph G is a graph description, such as a drawing, from which a formal specification could be constructed and labeled with the vertex names and edge names from G, so as to obtain a graph that conforms to the incidence rule for G.

The ***incidence matrix*** of a graph (without loops) G with vertices $v_1, v_2, \ldots, v_n$ and edges $e_1, e_2, \ldots, e_m$ is the $n \times m$ matrix M_I with

$$M_I[i,j] = \begin{cases} 0 & \text{if } v_i \text{ is not an endpoint of } e_j \\ 1 & \text{if } v_i \text{ is an endpoint of } e_j. \end{cases}$$

(In case loops are present, if e_j is a loop at v_i, then usually $M_I[i,j] = 2$, but sometimes $M_I[i,j] = 1$ even though this violates the properties that every column-sum equals 2 and every row-sum equals the degree of the corresponding vertex.)

Figure 1: Some fundamental infinite classes of graphs.



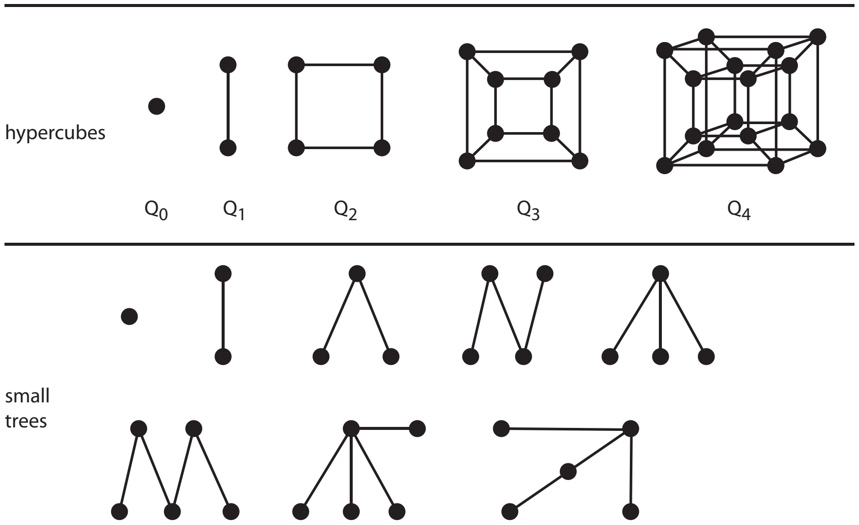


Figure 2: Some special graphs.

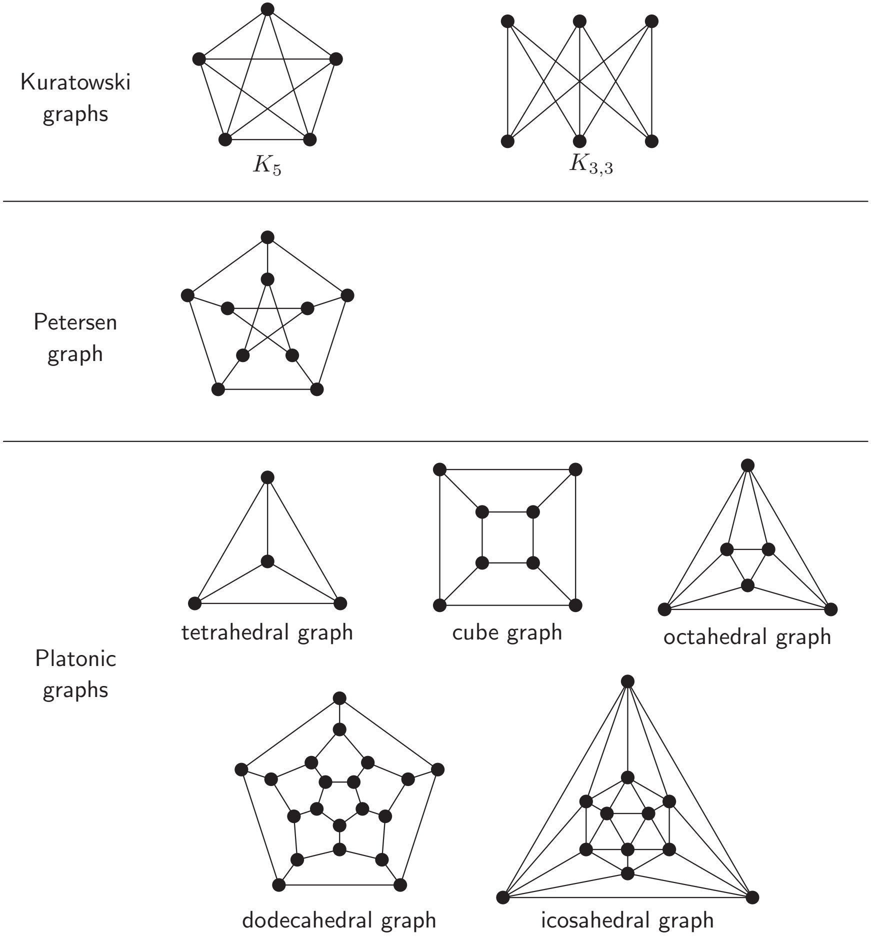


The ***adjacency matrix*** of a loop-free graph G with vertices $v_1, v_2, \ldots, v_n$ is the $n \times n$ matrix A with

$$A[i,j] = \text{the number of edges between } v_i \text{ and } v_j \text{ if } i \neq j.$$

If there are loops, then $A[i,i]$ is usually defined to be the number of loops at v_i.

A ***normalized drawing*** of a graph represents each vertex as a distinct point in the plane and each edge as a possibly curved line between endpoints, such that

- the interior of an edge does not contain any vertex;
- at most two edges cross at any point of the plane;
- two edges cross each other at most once;
- each edge crossing is normal, not a tangency.

A ***complete set of operations*** on graphs is a set from which all other operations can be constructed. The operations in a complete set are ***primitive*** if none can be derived from the other operations.

A ***graph computation package*** is a computer software system that represents graphs and includes a complete set of operations.

Facts:

1. Despite the redundancy, an incident-edge table is often used with an endpoint table in computer software, since it facilitates fast searching at the cost of relatively little space.

2. If a graph is simple, then its edges can be represented as endpoint pairs vw. Thus, the graph can be specified as a list of endpoint pairs and a list of isolated vertices.

3. If a graph is simple, then its incident-edge table can be represented as a table that gives the list of neighbors of every vertex.

4. If A is the adjacency matrix of graph G, then the (i,j)-entry of A^k is the number of walks (see §8.4.1) of length k from v_i to v_j in G.

5. *Matrix-tree theorem*: Let G be a graph, and let A be its adjacency matrix and D the diagonal matrix of the degrees of its vertices. Then the value of every cofactor of $D - A$ equals the number of spanning trees of G. (G. R. Kirchhoff, 1847)

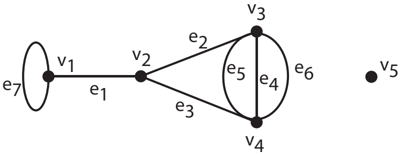
6. Given the incidence matrix of G, it is possible to obtain the incidence matrix for a subgraph H of G by deleting all rows and columns corresponding to vertices and edges that are not in H.

7. The most commonly used complete set of operations is adding a vertex, deleting a vertex, adding an edge, and deleting an edge.

8. Graph computation packages are built into mathematical computation systems such as Maple and Mathematica. They usually include display operations.

Examples:

1. The following normalized drawing, endpoint table, incident-edge table, incidence matrix and adjacency matrix all specify the same graph G.



endpoint table

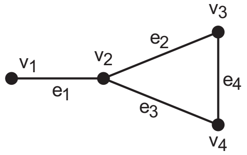
e_1	e_2	e_3	e_4	e_5	e_6	e_7
v_1	v_2	v_2	v_3	v_3	v_3	v_1
v_2	v_3	v_4	v_4	v_4	v_4	

incident-edge table

v_1	e_1	e_7		
v_2	e_1	e_2	e_3	
v_3	e_2	e_4	e_5	e_6
v_4	e_3	e_4	e_5	e_6
v_5				

$$M_I = \begin{array}{c|ccccccc} & e_1 & e_2 & e_3 & e_4 & e_5 & e_6 & e_7 \\ \hline v_1 & 1 & 0 & 0 & 0 & 0 & 0 & 2 \\ v_2 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ v_3 & 0 & 1 & 0 & 1 & 1 & 1 & 0 \\ v_4 & 0 & 0 & 1 & 1 & 1 & 1 & 0 \\ v_5 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array} \qquad A = \begin{array}{c|ccccc} & v_1 & v_2 & v_3 & v_4 & v_5 \\ \hline v_1 & 1 & 1 & 0 & 0 & 0 \\ v_2 & 1 & 0 & 1 & 1 & 0 \\ v_3 & 0 & 1 & 0 & 3 & 0 \\ v_4 & 0 & 1 & 3 & 0 & 0 \\ v_5 & 0 & 0 & 0 & 0 & 0 \end{array}$$

2. The following normalized drawing, list of endpoint pairs, lists-of-neighbors table, incidence matrix and adjacency matrix all specify the same simple graph H. It is a spanning subgraph of the graph G of Example 1, but it is *not* an induced subgraph.



endpoint pairs:
$v_1v_2, v_2v_3, v_2v_4, v_3v_4$

lists-of-neighbors

$v_1:$	v_2		
$v_2:$	v_1	v_3	v_4
$v_3:$	v_2	v_4	
$v_4:$	v_2	v_3	

$$M_I = \begin{array}{c|cccc} & e_1 & e_2 & e_3 & e_4 \\ \hline v_1 & 1 & 0 & 0 & 0 \\ v_2 & 1 & 1 & 1 & 0 \\ v_3 & 0 & 1 & 0 & 1 \\ v_4 & 0 & 0 & 1 & 1 \end{array} \qquad A = \begin{array}{c|cccc} & v_1 & v_2 & v_3 & v_4 \\ \hline v_1 & 0 & 1 & 0 & 0 \\ v_2 & 1 & 0 & 1 & 1 \\ v_3 & 0 & 1 & 0 & 1 \\ v_4 & 0 & 1 & 1 & 0 \end{array}$$

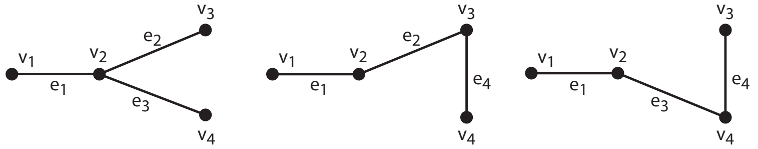
3. Squaring and cubing the adjacency matrix of Example 2 provides an illustration of Fact 4.

$$A^2 = \begin{array}{c|cccc} & v_1 & v_2 & v_3 & v_4 \\ \hline v_1 & 1 & 0 & 1 & 1 \\ v_2 & 0 & 3 & 1 & 1 \\ v_3 & 1 & 1 & 2 & 1 \\ v_4 & 1 & 1 & 1 & 2 \end{array} \qquad A^3 = \begin{array}{c|cccc} & v_1 & v_2 & v_3 & v_4 \\ \hline v_1 & 0 & 3 & 1 & 1 \\ v_2 & 3 & 2 & 4 & 4 \\ v_3 & 1 & 4 & 2 & 3 \\ v_4 & 1 & 4 & 3 & 2 \end{array}$$

For instance, the three walks of length 3 from v_4 to v_3 are as follows:

$$\langle v_4, e_3, v_2, e_3, v_4, e_4, v_3\rangle,\ \langle v_4, e_4, v_3, e_4, v_4, e_4, v_3\rangle,\ \langle v_4, e_4, v_3, e_2, v_2, e_2, v_3\rangle.$$

4. As an illustration of the Kirchhoff matrix-tree theorem of Fact 5, observe that the graph of Example 2 has the following three spanning trees.



The value of the $(2,2)$-cofactor of the matrix $D - A$ is also equal to 3:

$$D - A = \begin{array}{c} \\ v_1 \\ v_2 \\ v_3 \\ v_4 \end{array}\!\!\begin{array}{c} \begin{array}{cccc} v_1 & v_2 & v_3 & v_4 \end{array} \\ \begin{pmatrix} 1 & -1 & 0 & 0 \\ -1 & 3 & -1 & -1 \\ 0 & -1 & 2 & -1 \\ 0 & -1 & -1 & 2 \end{pmatrix} \end{array} \qquad \text{cofactor} = \begin{vmatrix} 1 & 0 & 0 \\ 0 & 2 & -1 \\ 0 & -1 & 2 \end{vmatrix} = 3.$$

8.2 GRAPH MODELS

Modeling with graphs is one of the main ways in which discrete mathematics has been applied to real world problems. This section gives a list of some of the ways in which graphs are used as mathematical models. Further information can be found in for example [ArGr06] and [Ro76].

8.2.1 ATTRIBUTES OF A GRAPH MODEL

Definitions:

A ***mathematical representation*** of a physical or behavioral phenomenon is a correspondence between the parts and processes of that phenomenon and a mathematical system of objects and functions.

A ***model*** of a physical or behavioral phenomenon is the mathematical object or function assigned to that phenomenon under a mathematical representation.

Modeling is the mathematical activity of designing models and comprehensive mathematical representations of physical and behavioral phenomena.

A ***graph model*** is a mathematical representation that involves a graph.

Examples:

Table 1 gives many examples of graph models. Each example states what the vertices and edges (or arcs) represent and where in the *Handbook* details can be found.

Table 1: Directory of graph models.

subject area *and application*	*vertex attributes and meaning* *edge/arc attributes and meaning*	*reference*
computer programming flowcharts	vertex labels are program steps edge directions show flow	§8.1.1
social organization social networks	vertices are persons edges represent interactions	§8.1.1

subject area *and application*	*vertex attributes and meaning* *edge/arc attributes and meaning*	*reference*
civil engineering road networks	vertices are road intersections edges are roads	§8.1.1, §8.3.1
operations research scheduling	vertices are activities arcs show operational precedence	§8.3.1
sociology hierarchical dominance	vertices are individuals arcs show who reports to whom	§8.3.1
computer programming subprogram-calling diagram	vertices are subprograms arcs show calling direction	§8.3.1
ecology food webs	vertices are species arcs show who eats whom	§8.3.1
operations research scheduling	vertices are activities edges are activity conflicts	§8.3.1, §8.6.1
genealogy family trees	vertices are family members arcs show parenthood	§8.3.1
set theory binary relations	vertices are elements arcs show relatedness	§8.3.1
probabilistic analysis Markov models	vertices are process states edges are state transitions	§8.3.2
traffic control assigning one-way streets	vertices are intersections edges are streets	§8.3.3
partially ordered sets Hasse diagrams	vertices are elements arcs show covering relation	§8.3.4
computer engineering communications networks	vertices are computational nodes arcs are communications links	§8.4.2
operations research transportation networks	vertices are supply and demand nodes arcs are supply lines	§8.4.2
walking tours Seven Bridges of Königsberg	vertices are land masses edges are bridges	§8.4.3
postal delivery routing Chinese Postman Problem	vertices are street intersections edges are streets	§8.4.3
information theory Gray codes	vertices are binary strings edges are single-bit changes	§8.4.4
radio broadcasting assignment of frequencies	vertices are broadcast stations edges are potential interference	§8.6.1
chemistry preventing explosions	vertices are chemicals edges are co-combustibility	§8.6.1
cartography map-coloring	regions are countries edges are shared borders	§8.6.4

subject area *and application*	*vertex attributes and meaning* *edge/arc attributes and meaning*	*reference*
highway construction avoiding overcrossings	vertices are road intersections edges are roads	§8.7.1
electrical network boards avoiding insulation	vertices are circuit components edges are wires	§8.7.1

information management binary search trees	vertices are data records edges are decisions	§18.1.4
computer operating systems priority trees	vertices are jobs edges are priority relations	§18.1.5
physical chemistry counting isomers	vertices are atoms edges are molecular bonds	§9.3.2
network optimization min-cost spanning trees	edges are connections edge-labels are costs	§10.1.1
bipartite matching personnel assignment	parts are people and jobs edges are job-capabilities	§10.2.2
network optimization shortest path	vertices are locations edge-labels are distances	§10.3.1
traveling salesman routing shortest complete tour	vertices are locations edge-labels are distances	§10.7.1

8.3 DIRECTED GRAPHS

Assigning directions to the edges of a graph is useful in modeling, and is natural whenever order is important, e.g., in a hierarchical structure or a one-way road system. Also, any graph may be viewed as a digraph, by replacing each edge with two directed edges, one in each direction. Many graph problems are best solved as special cases of digraph problems, for instance, finding shortest paths, maximum flows, and connectivity.

8.3.1 DIGRAPH MODELS AND REPRESENTATIONS

Most terminology applies equally well to graphs and digraphs. The definitions below are special to digraphs or take on a somewhat different meaning for digraphs. Further, where it is clear that only digraphs are being discussed, "directedness" is often an implicit attribute of an "edge", "path", and other terms.

Definitions:

A ***directed graph***, or ***digraph***, consists of a set V of ***vertices*** and a set E of ***directed edges*** or ***arcs***, and an ***incidence function*** that assigns to each edge a ***tail*** and a ***head***.

The ***tail*** of an arc is the vertex it leaves, and the ***head*** is the vertex it enters. An arc with tail u and head v is often denoted by uv.

A ***simple digraph*** has no self-loops or multi-arcs.

The ***underlying graph of a digraph*** is the graph obtained from the digraph by replacing every directed edge by an undirected edge.

The ***out-degree*** of vertex v, denoted $\delta^+(v)$, is the number of arcs with tail at v.

The ***in-degree*** of vertex v, denoted $\delta^-(v)$, is the number of arcs with head at v.

A digraph is ***transitive*** if whenever it contains an arc from u to v and an arc from v to w, it also contains an arc from u to w.

The ***adjacency matrix*** of a digraph is the matrix $A = [a_{ij}]$ where a_{ij} is the number of arcs from v_i to v_j.

The ***incidence matrix*** of a digraph with no self-loops is the matrix $M = [b_{ij}]$, where $b_{ij} = +1$ if v_i is the tail of e_j, $b_{ij} = -1$ if v_i is the head of e_j, and $b_{ij} = 0$ otherwise. (There is no standard convention for self-loops.)

Facts:

1. *Simple-digraph terminology*: In a context focusing on simple digraphs, there is often a different convention:

- "digraph" refers to a simple digraph;
- a directed graph with multi-arcs is called a *multidigraph*;
- a directed graph with self-loops is called a *pseudodigraph*;

2. *Alternative "path" terminology*: There is an alternative convention in which a (directed) "path" may use vertices and arcs more than once, but an "elementary path" does not repeat arcs, and a "simple path" does not repeat vertices (and, hence, does not repeat arcs either). See §8.3.2.

3. A digraph is frequently represented by an *arc list*, in which each arc is represented by an ordered pair uv, where u is its tail and v is its head. There is a separate entry for each arc, so that uv occurs as often as the number of such arcs. A list of the isolated vertices plus such an arc list completely specifies a digraph.

4. Another common specification of a digraph is the *lists-of-neighbors representation*. For each vertex u, there is a list, which contains the head of each arc whose tail is u. Thus a vertex v occurs in that list as many times as there are arcs from u to v.

5. The incidence matrix is another way to represent a digraph. Since all but one or two of the entries in every column are zero, the incidence matrix is an inefficient representation.

6. The adjacency matrix is a way to specify a digraph when there is no reason to identify the arcs by name.

7. A digraph can be represented by a $2 \times |E|$ *incidence table* in which the tail and head of arc e appear in column e. Direction on an arc can be indicated by a convention as to whether tail or head appears in the first row.

8. The row-sum in a directed adjacency matrix equals the out-degree of the corresponding vertex. The column-sum equals the in-degree.

9. In a digraph, the sum of the in-degrees, the sum of the out-degrees, and the number of arcs are all equal to each other; that is, $\sum_{v \in V} \delta^-(v) = \sum_{v \in V} \delta^+(v) = |E|$.

Examples:

1. The following arc list, incidence table, list-of-neighbors, and adjacency matrix all represent the digraph G.

arc list:

$uv,\ vv,\ vw,\ xw,\ xw,\ ux,\ xu$

incidence table:

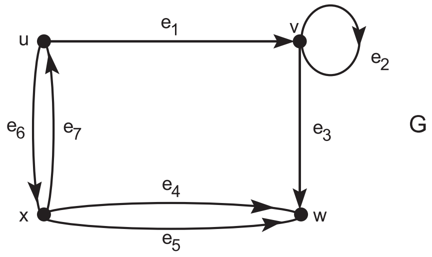
e_1	e_2	e_3	e_4	e_5	e_6	e_7
u	v	v	x	x	u	x
v	v	w	w	w	x	u

lists-of-neighbors:

$u : v, x$
$v : v, w$
$w : \emptyset$
$x : w, w, u$

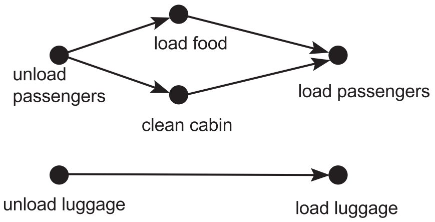
adjacency matrix:

$$\begin{array}{c|cccc} & u & v & w & x \\ \hline u & 0 & 1 & 0 & 1 \\ v & 0 & 1 & 1 & 0 \\ w & 0 & 0 & 0 & 0 \\ x & 1 & 0 & 2 & 0 \end{array}$$



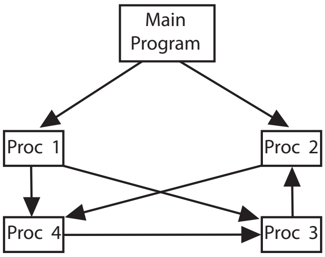
2. *Civil Engineering*: A road network in which at least some of the roads are one-way can be modeled by a digraph. The vertices are road junctures; each two-way road is represented by a pair of arcs, one in each direction. Loops are allowed, and they may represent "circles" that occur in housing developments and in industrial parks. Similarly, multi-arcs may occur.

3. *Operations Research*: A large project consists of many smaller tasks with a *precedence relation*—some tasks must be completed before certain others can begin. The vertices represent tasks, and there is an arc from u to v if task u must be completed before v can begin. For instance, in the following figure it is necessary both that food is loaded and the cabin is cleaned before passengers are loaded.

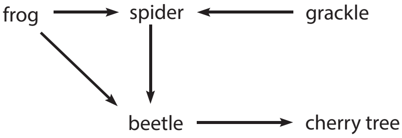


4. *Sociology and Sociobiology*: A business (or army, or society, or ant colony) has a *hierarchical dominance* structure. The vertices are the employees (soldiers, citizens, ants) and there is an arc from u to v if u dominates v. If the chain of command is unique, with a single leader, and if only arcs representing immediate authority are included, then the result is a *rooted tree*. (See §9.1.2.)

5. *Computer Software Design*: A large program consists of many subprograms, some of which can invoke others. Let the vertices of D be the subprograms, and let there be an arc from u to v if subprogram u can invoke subprogram v. Then the *call graph* D encapsulates all possible ways control can flow within the program. Directed cycles represent indirect recursion, and serve as a warning to the designer to ensure against infinite loops. See the following figure, where subprogram 2 can call itself indirectly.



6. *Ecology*: A *food web* is a simple digraph in which vertices represent species and in which there is an arc from u to v if species u eats species v. The following figure shows a small food web.



7. *Operations Research*: A sequence of books must be printed and bound, using one press and one binding machine. Suppose that book i requires time p_i for printing and time b_i for binding. It is desired to print the books in such an order that the binding machine is never idle: when it finishes one book, the next book should already be printed. The vertices of a digraph D can represent the books. There is an arc from book i to book j if $p_j \leq b_i$. Then any path through all the vertices corresponds to a permissible ordering.

8. *Genealogy*: A "family tree" is a digraph where the orientation is traditionally given not by arrows but by the direction down for later generations. Despite the name, a family tree is usually not a tree, since people commonly marry distant cousins, knowingly or unknowingly.

9. *Binary Relations*: To any binary relation R on a set V (see §1.4.1) a digraph $D(V, R)$ can be associated: the vertices are the elements of V, and there is an arc from u to v if $(u, v) \in R$. Conversely, every digraph without multiple arcs defines a binary relation on its vertices. The relation R is transitive if and only if the digraph $D(V, R)$ is transitive.

8.3.2 PATHS, CYCLES, AND CONNECTEDNESS

Definitions:

A ***directed walk*** is a sequence of arcs such that the head of one arc is the tail of the next arc.

The ***length*** of a directed walk is the number of arcs in the sequence.

A ***closed directed walk*** is a directed walk that begins and ends at the same vertex.

A ***directed trail*** is a directed walk in which no arc is repeated.

A ***directed path*** is a directed trail in which no vertex is repeated.

A ***directed cycle*** is a closed directed trail in which no vertices are repeated, except the initial and final vertex.

Vertex v is ***reachable*** from vertex u if there is a directed path from u to v.

A ***basis for a digraph*** is a set of vertices V' such that every vertex not in V' is reachable from V' and such that no proper subset of V' has this property.

The ***distance*** from a vertex u to a vertex v in a digraph is the length of a shortest directed path from u to v.

A digraph is ***strongly connected*** (or ***diconnected***, or ***strong***) if every vertex is reachable from every other vertex.

A digraph is ***unilaterally connected*** (or ***unilateral***) if for every pair of vertices u and v, there is either a uv-path or a vu-path.

A digraph is ***weakly connected*** (or ***weak***) if the underlying graph is connected.

The digraph is ***disconnected*** if the underlying graph is disconnected.

A ***strong component*** of a digraph is a maximal subgraph that is strongly connected.

A digraph is ***reducible*** if the vertex set can be partitioned into a disjoint union $V_1 \cup V_2$ so that all arcs joining V_1 and V_2 go from V_1 to V_2.

The ***condensation*** D^* of a digraph D is the simple digraph whose vertices are the strong components $\{V_1, V_2, \ldots, V_k\}$ of D, with an arc $V_iV_j \in E_{D^*}$ if and only if there is an arc vv' in D such that $v \in V_i$ and $v' \in V_j$.

The ***converse of a digraph*** D is obtained by reversing the directions of all the arcs of D.

The ***directional dual*** of a theorem about digraphs is the statement obtained by replacing each property in the theorem statement by its converse.

Facts:

1. Using a pencil on a drawing of a digraph, a directed walk can be traversed by following the arrows without lifting the pencil from the graph.

2. Distance in digraphs need not be symmetric. That is, the distance from u to v might be different from the distance from v to u.

3. If A is the adjacency matrix of D, then the ij entry of A^n is the number of n-arc walks from v_i to v_j.

4. Let δ^+ be the smallest out-degree of a simple digraph D. If $\delta^+ > 0$, then D has a cycle of length at least $\delta^+ + 1$.

5. Let δ^- be the smallest in-degree of a simple digraph D. If $\delta^- > 0$, then D has a cycle of length at least $\delta^- + 1$.

6. The directional dual of a theorem about digraphs is a theorem about digraphs.

7. Fact 5 is the directional dual of Fact 4.

8. A digraph D is Eulerian (see §8.4.3) if and only if the underlying graph is connected and in-degree equals out-degree at every vertex.

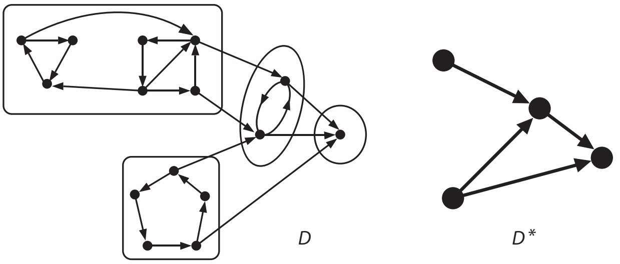
9. A digraph D has an Euler uv-trail (where $u \neq v$) if the following conditions hold:

- the out-degree of vertex u exceeds the in-degree by one; that is, $d^+(u) = d^-(u)+1$;
- the in-degree of v exceeds the out-degree by one; that is, $d^-(v) = d^+(v) + 1$;
- at every other vertex, the in-degree equals the out-degree; that is, $d^-(w) = d^+(w)$ for all $w \neq u, v$.

Other Euler-type results for graphs generalize to digraphs as well.

10. Let δ be the minimum of all in- and out-degrees of simple digraph D. If $\delta \geq |V|/2 > 1$, then D contains a Hamilton cycle (see §8.4.4).

11. The strong components of a digraph D partition the vertices of D, but not the arcs. However, the maximal unilateral subgraphs do partition the arcs. If V_1, V_2 are the vertex sets of two strong components of D, then all arcs between V_1 and V_2 face the same way—either from V_1 or to V_1. See the following figure.



12. The condensation of any digraph is an acyclic digraph (see §8.3.4). See the figure for the previous fact.

13. A digraph is reducible if and only if its condensation has at least two vertices.

14. A digraph is unilateral if and only if its condensation is a path.

15. A set V' is a basis of a digraph D if and only if V' consists of one vertex from each strong component of D that has in-degree 0 in D^*. Thus, every basis of a digraph has the same number of vertices.

16. The eigenvalues of a digraph D are the union (counting multiplicities) of the eigenvalues of its strong components. (See §8.10.2.)

Examples:

1. Let u, v be vertices of an n-vertex digraph D with adjacency matrix A. If v is reachable from u, then some uv-path has length $\leq n-1$. Thus, D is strong if and only if every entry of $\sum_{k=0}^{n-1} A^k$ is positive. There are more computationally efficient tests for diconnectivity: the Floyd-Warshall algorithm (see §10.3.3) and directed depth-first search (see §9.2.1).

2. Let M be an arbitrary square matrix. Computation of the eigenvalues of M can sometimes be sped up as follows. Create matrix A by replacing each nonzero entry of M by a '1', and then let D be the digraph with adjacency matrix A. The eigenvalues of M are the union of the eigenvalues of the minors of M indexed by the strong components of D. If M is *sparse* (few nonzeros), then digraph D will usually have many small components and this approach will be efficient.

3. *Markov models*: Let V represent a set of states and E the possible transitions of a Markov process (see §7.7). Then walks through D represent "histories" that the process can follow.

8.3.3 ORIENTATIONS

There are many natural questions concerning when the edges of an undirected graph could be assigned directions so as to obtain a certain sort of digraph. For instance, when can a graph be oriented to obtain a strong digraph? An application of this last question is to determine when a set of roads could all be made one-way, while keeping all points reachable from all others.

Definitions:

An ***orientation*** of a graph is an assignment of directions to its edges, thereby making it a digraph.

An orientation of a graph is ***strong*** if, for each pair of vertices u, v, there is a directed path from u to v and a directed path from v to u.

An orientation of a graph is ***transitive*** if, whenever there is an arc from u to v and an arc from v to w, there is also an arc from u to w.

A graph that admits a transitive orientation is called a ***comparability graph***.

A ***cut-edge*** (or ***bridge***) of a graph is an edge whose removal would increase the number of components (see §8.4.1).

A ***2-edge-connected*** graph G is connected and has no cut-edge.

A ***generalized circuit*** in a graph is a closed walk (see §8.4.1) that uses each edge at most once in each direction.

A ***triangular chord*** for a closed walk (see §8.4.1) $u_1, u_2, \ldots, u_k, u_1$ is a proper edge that joins two vertices exactly two apart on the walk.

Facts:

1. Let $\chi(G)$ be the chromatic number (see §8.6.1) of graph G. Then every orientation of G has a path of length at least $\chi(G) - 1$.

2. A graph G has a strong orientation if and only if G is 2-edge-connected. (H. Robbins, 1939)

3. A graph G is a comparability graph if and only if every generalized circuit of G of odd length > 3 has a triangular chord.

4. Algorithms 1 and 2 give ways of creating a strong orientation in a 2-edge-connected graph.

Algorithm 1: **Naive algorithm for creating a strong orientation.**

```
{This algorithm is good to use by hand for small graphs}
input: a 2-edge-connected graph $G$
output: a strong orientation of $G$

$H$ := any cycle in $G$
direct $H$
while some vertex of $G$ is not in directed subgraph $H$
  $v$ := a vertex not in $H$
  find two edge-disjoint paths from $v$ to $H$
```

```
    {Two such paths exist because $G$ is 2-edge-connected}
  direct one path from $v$ to $H$ and the other from $H$ to $v$
  $H := H$ with these two subgraphs added
orient any remaining edges arbitrarily
```

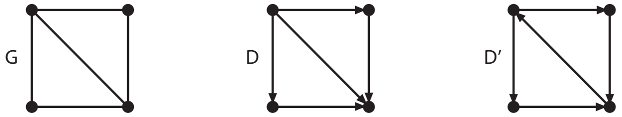
Algorithm 2: **Better algorithm for creating a strong orientation.**

```
{A good algorithm for large graphs or for computer implementation}
input: a 2-edge-connected graph
output: a strong orientation

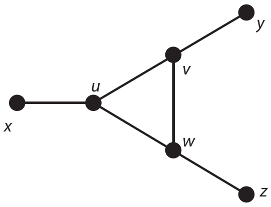
select an arbitrary vertex as root
construct the depth-first search spanning tree from that root  {See §9.2.1.}
orient the tree edges downward from the root
orient all back edges upward toward the root
orient all cross edges arbitrarily
```

Examples:

1. In the figure below the digraph D is a weak transitive orientation of the graph G and D' is a strong nontransitive orientation.



2. The following graph is not transitively orientable, and $x, u, v, y, v, w, z, w, u, x$ are the vertices of a generalized circuit without a triangular chord.



3. *Traffic control*: The flow of traffic on crowded city streets can sometimes be improved by making streets one-way. When this is done, it is necessary that a car can travel legally between any two locations. Assigning directions to the edges of the graph representing the street grid is an orientation of this graph, and cars can travel legally between any two points if and only this graph has a strong orientation. Consequently, by Robbins' theorem (Fact 2), to make all the streets one-way without losing mutual accessibility of locations, it is necessary and sufficient that the grid of streets be 2-edge-connected.

8.3.4 DIRECTED ACYCLIC GRAPHS

Definitions:

A digraph is ***acyclic*** if it has no *directed* cycles. A directed acyclic graph is sometimes called a DAG.

A ***source*** of a digraph is a vertex of in-degree zero.

A ***sink*** of a digraph is a vertex of out-degree zero.

A ***linear extension ordering*** of the n vertices of a digraph is a consecutive labeling $v_1, v_2, \ldots, v_n$ so that, if there is an arc from v_i to v_j, then $i < j$. (See also §11.2.5.)

A ***topological sort***, or ***topsort***, is an algorithm that assigns a linear extension ordering to a DAG.

Facts:

1. Every DAG has at least one source, and by duality, at least one sink.

2. Every DAG has a unique basis (see §8.3.2), namely, the set of all its sources.

3. Topsort yields a linear ordering for the vertices that makes the adjacency matrix of a DAG upper-triangular.

4. Doing a preliminary topsort permits some optimization problems about paths to be solved subsequently by a single algorithmic pass through the vertices in the topsort order; see, for example, §16.4.1 (critical paths).

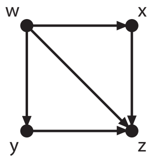
5. Algorithm 3 provides a simple algorithm for topological sort.

Algorithm 3: **Naive topological sort.**

```
{Construct a linear extension ordering for a DAG}
input: a DAG $D$
output: a numbering of the vertices in a topsort order
$H := D$; $k := 1$
while $V_H \neq \emptyset$
    $v_k :=$ a vertex of $H$ of in-degree 0  {This exists; see Fact 1}
    $H := H - v_k$  {Remaining graph is still a DAG}
    $k := k + 1$
```

Examples:

1. In the following digraph vertex w is a source and vertex z is a sink. It is a DAG, even though the underling graph has cycles. Labeling the vertices either in the order w, x, y, z or w, y, x, z is a linear extension ordering.



2. Consider any digraph whose vertices represent instantaneous events, and whose arcs go from earlier events to later events. Any such digraph is acyclic. Conversely, any digraph whose vertices represent procedural steps and whose arcs represent required precedence can be scheduled (using a topological sort) so that arcs do in fact go forward in time.

3. The Hasse diagram of a poset (see §11.1.1) is a DAG, as is the entire graph of a poset (arc from u to v if and only if $u \geq v$).

8.3.5 TOURNAMENTS

Definitions:

A ***tournament*** is a digraph with exactly one arc between each pair of distinct vertices. An ***n-tournament*** has n vertices.

The ***score vector*** of a tournament is the sequence of out-degrees of the vertices (number of arcs leaving each vertex), usually in ascending order.

A tournament is ***regular*** if every vertex has the same out-degree.

A tournament is ***strong*** if there is a directed path between each pair of vertices in both directions.

A tournament is ***transitive*** if, whenever there is an arc from u to v and from v to w, there is also an arc from u to w.

A tournament is ***irreducible*** if there is no bipartition V_1, V_2 of the vertices such that all arcs between V_1 and V_2 go from V_1 to V_2.

Vertex u of a tournament ***dominates*** vertex v if there is an arc from u to v.

A ***transmitter*** in a digraph is a vertex that has an arc to every other vertex.

A ***king*** in a digraph is a vertex from which there is a path of length 1 or 2 to all other vertices.

A ***single-elimination competition*** is a contest from which a competitor is eliminated after the first loss.

Facts:

1. Every tournament has a Hamilton path (see §8.4.4), in fact an odd number of them.

2. The following statements are equivalent for any n-tournament T:

- T is strong;
- T is irreducible;
- T has a Hamilton cycle;
- T has cycles of all lengths $3, 4, \ldots, n$;
- Every vertex of T is on cycles of all lengths $3, 4, \ldots, n$.

3. Almost all tournaments are strong, in the sense that, as $n \to \infty$, the fraction of labeled n-tournaments that are strong approaches 1.

4. The following are equivalent for a tournament:

- the tournament is transitive;
- the tournament contains no cycles;

- the tournament contains no 3-cycles;
- the tournament is a total (i.e., linear) order;
- the tournament has a unique Hamilton path.

5. Every tournament has a king.

6. The king of a tournament is unique if and only if it is a transmitter. Otherwise, there are at least three kings.

7. In a tournament, almost every vertex is a king, for as $n \to \infty$, the fraction of n-tournaments in which every vertex is a king approaches 1.

8. *Score vector characterizations*: A nondecreasing sequence S of nonnegative integers $s_1, s_2, \ldots, s_n$ is the score vector of an n-tournament if and only if

$$\sum_{i=1}^{k} s_i \geq \binom{k}{2}, \quad \text{for } k = 1, 2, \ldots, n{-}1, \quad \text{and} \quad \sum_{i=1}^{n} s_i = \binom{n}{2}.$$

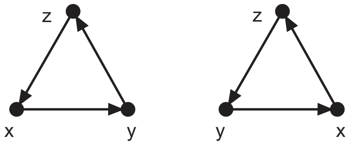
Or equivalently, if and only if the sequence S' obtained by deleting any one s_i and reducing the largest remaining $n - s_i - 1$ terms by 1 is a score vector of an $(n{-}1)$-tournament.

9. The second characterization of Fact 8 leads to a recursive algorithm to construct a tournament having a specified score vector. See Example 4.

10. A nonnegative integer sequence $s_1 \leq s_2 \leq \cdots \leq s_n$ is the score vector of a *strong* n-tournament if and only if

$$\sum_{i=1}^{k} s_i > \binom{k}{2}, \quad \text{for } k = 1, 2, \ldots, n{-}1, \quad \text{and} \quad \sum_{i=1}^{n} s_i = \binom{n}{2}.$$

11. The two tournaments in the following figure are isomorphic as unlabeled tournaments, but distinct as labeled tournaments.



There are $2^{\binom{n}{2}}$ distinct *labeled* tournaments, because for each pair of vertices $\{u, v\}$, there are two choices for which way to direct the edge. If c_n is the number of distinct *unlabeled* n-tournaments, then

$$c_n > \frac{2^{\binom{n}{2}}}{n!} \quad \text{and} \quad \lim_{n \to \infty} \frac{c_n}{2^{\binom{n}{2}}} / n! = 1.$$

See §8.9.3 and §8.9.4.

12. When a tournament is acyclic, it corresponds to a unique total ordering (Fact 4), so the ranking is clear. However, almost all tournaments are strong (Fact 3). Moreover, in a large tournament, almost every vertex is a king (Fact 7). These are reasons why it is difficult to give a satisfactory general method to rank tournaments.

13. *Scheduling tournaments*: To speed up the play of an n-tournament, games can be scheduled in parallel. If n is even, then at most $n/2$ of the $\binom{n}{2}$ games can be played simultaneously, so at least $n - 1$ rounds are needed. However, if n is odd, then only $(n - 1)/2$ games can be played simultaneously, so at least n rounds are needed. In fact, this minimum number of rounds can be obtained, and several methods of scheduling tournaments, subject to various additional conditions, have been devised. See [Mo15].

Examples:

1. A round-robin sports tournament in which there are no ties is a tournament in the mathematical sense defined above. However, a single-elimination competition (e.g., most tennis tournaments) is not a tournament as defined above.

2. It has been observed that in every small flock of hens, *every* pair of hens establish a dominance relation—the weaker of the two allows the stronger to peck her. Thus, this pecking order is a tournament.

3. In a "paired comparison experiment", a subject is asked to state a preference in each pair chosen from n items. This amounts to a tournament, where there is an arc ij if item i is preferred to item j.

4. Is there a tournament on vertices (a, b, c, d, e) with respective scores $(1, 2, 2, 2, 3)$? Deleting e according to the second part of Fact 8 leaves vertices (a, b, c, d) with scores $(1, 2, 2, 1)$. Next deleting d leaves (a, b, c) with scores $(1, 1, 1)$. The obvious tournament with such a score vector is a 3-cycle. Next reinsert vertex d, making it dominate vertex a only. Then reinsert vertex e, making it dominate a, b, c. This 5-tournament has the specified score vector $(1, 2, 2, 2, 3)$.

5. *Ranking real tournaments*: Ranking teams by their order along a Hamilton path (see Fact 1) is rarely satisfactory, because that order is unique only for transitive tournaments (Fact 4); in most cases, there are a great many Hamilton paths. Ranking by score vector usually creates ties, and a team with few wins may deserve a better rank if those teams it beats have many wins. So one may consider the *second-order score vector*, where each team's score is the sum of the out-degrees of the teams it beats. This can be continued to nth-order score vectors. There is a limit ranking obtained this way (often quite satisfactory), related to the eigenvalues of the digraph. See [Mo15] for more detail and references.

8.4 DISTANCE, CONNECTIVITY, TRAVERSABILITY, & MATCHINGS

Graphs often serve as models for transportation and communication network problems. Movement from one node to another in the network corresponds to the graph-theoretic notion of a walk, while the connectivity of a graph is a measure of resistance to a communications cutoff.

8.4.1 WALKS, DISTANCE, AND CYCLE RANK

Definitions:

A ***walk*** in a graph is an alternating sequence $v_0, e_1, v_1, \ldots, e_r, v_r$ of vertices and edges in which each edge e_i joins vertices v_{i-1} and v_i. Such a walk is also called a v_0, v_r-*walk*.

The ***length*** of a walk is the number of occurrences of edges in it. An edge that occurs more than once is counted each time it occurs.

A ***trail*** is a walk in which all of the edges are different.

A walk or trail is ***open*** if its final vertex is different from its initial vertex.

A walk or trail is ***closed*** if its final vertex is the same as its initial vertex.

A ***path*** is a trail in which all the vertices are different. A path from v_0 to v_r is called a v_0, v_r*-path*. (The word "path" also refers to a type of graph; see §8.1.3.)

A ***cycle*** is a closed trail of positive length in which all the vertices are different except for the initial and final vertex. (The word "cycle" also refers to a type of graph; see §8.1.3.)

A graph is ***connected*** if each pair of vertices is joined by a path.

A ***component*** of a graph is a maximal connected subgraph of the graph.

The vertex v is ***reachable*** from vertex u in a graph if there is a u, v-path in the graph.

An ***isolated vertex*** of a graph is a vertex with no incident edges.

The ***distance*** $d(v, w)$ between two vertices v and w of a graph is the length of a shortest path between them, with $d(v, v) = 0$, and $d(v, w) = \infty$ if there is no path between v and w.

The ***diameter*** of a connected graph is the maximum distance between two of its vertices.

The ***eccentricity*** of a vertex v of a connected graph is the greatest distance from v to another vertex.

The ***radius*** of a connected graph is the minimum eccentricity among all the vertices of the graph.

The ***center*** of a connected graph is the set of vertices of minimum eccentricity.

The ***cycle rank*** (or ***first Betti number***), denoted by $\beta_1(G)$, of a connected graph $G = (V, E)$ is $|E| - |V| + 1$.

Facts:

1. *Alternative terminology*: Sometimes "circuit" is used to mean what is here called a closed trail.

2. In a simple graph, a walk may be represented as a string of vertices $v_0 v_1 \ldots v_r$, without mentioning the edges.

3. The distance function on the vertex set of any connected graph G is a metric; i.e., the following rules hold for all vertices u, v, and w in G:

- $d(v, w) \geq 0$, with equality if and only if $v = w$;
- $d(w, v) = d(v, w)$;
- $d(u, w) \leq d(u, v) + d(v, w)$, with equality if and only if v is on a shortest path from u to w.

4. There are polynomial-time algorithms for finding a shortest path between vertices. (See §10.3.2.)

5. A graph is connected if and only if it has a spanning tree.

6. A graph is disconnected if and only if there is a partition of its vertex set into nonempty sets A and B so that no edge has one end in A and the other in B.

7. The relation "is reachable from" is an equivalence relation on the vertex set. The equivalence classes of this relation induce the components.

8. A graph is connected if every vertex is reachable from every other vertex.

9. In a simple graph, the minimum length of a cycle is at least 3. In a general graph, a self-loop is a 1-cycle, and a 2-cycle is formed by a pair of vertices joined by a pair of parallel edges.

10. The cycle rank $\beta_1(G)$ of a connected graph G equals the number of edges in the complement of a spanning tree for G.

11. The cycle rank $\beta_1(G)$ of a connected graph G is equal to the rank of a vector space over $\mathcal{Z}_2$ whose domain is the set of cycles of G.

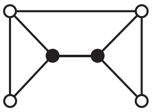
12. The cycle rank of a connected planar graph G equals the number of regions in a plane drawing of G, *minus* the exterior region.

13. The following table gives the cycle rank of some families of graphs.

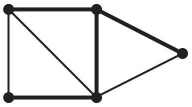
graph	*cycle rank*
bouquet B_n	n
dipole D_n	$n-1$
complete graph K_n	$\frac{(n-2)(n-1)}{2}$
complete bipartite graph $K_{m,n}$	$(m-1)(n-1)$
cycle graph C_n	1
wheel W_n	n
hypercube Q_n	$(n-2)2^n+1$
any tree	0

Example:

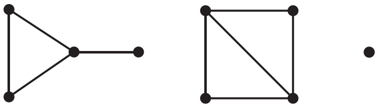
1. The following connected graph has diameter 3 and radius 2. The vertices in its center are indicated by solid dots.



2. The cycle rank of the following connected graph is 3. Observe that there are three edges in the complement of the indicated spanning tree.



3. The following disconnected graph has three components, one of which is an isolated vertex.



8.4.2 CONNECTIVITY

Definitions:

A ***cut-vertex*** of a graph G (or ***cut-point*** or ***articulation point***) is a vertex v such that $G - v$ has more components than G. (In topological analysis of nonsimple graphs, sometimes a vertex attached to a self-loop is also considered to be a cut-vertex.)

A ***nonseparable*** graph is a connected graph with no cut-vertices.

A ***block*** of a graph is a maximal nonseparable subgraph.

An ***cut-edge*** of a graph G is an edge e such that $G - e$ has more components than G (in which case there is just one more).

A ***disconnecting set of vertices*** (or ***cutset***) in a connected graph is a set of vertices whose removal yields a disconnected graph.

A ***disconnecting set of edges*** in a connected graph is a set of edges whose removal yields a disconnected graph.

The ***zeroth Betti number*** $\beta_0(G)$ of a graph G is the number of components in G. Elsewhere this is sometimes denoted by $c(G)$ or $\omega(G)$.

The (***vertex***) ***connectivity*** $\kappa(G)$ is the number of vertices in a smallest disconnecting set of vertices. By convention, $\kappa(K_n) = n - 1$.

The ***edge connectivity*** $\kappa'(G)$ is the number of edges in a smallest disconnecting set of edges.

A graph is ***k-connected*** if $\kappa(G) \geq k$.

A graph is ***k-edge-connected*** if $\kappa'(G) \geq k$.

Facts:

1. A vertex is a cut-vertex if and only if it lies on all paths between two other vertices.

2. Every nontrivial graph has at least two vertices that are not cut-vertices.

3. An edge is a cut-edge if and only if it is not contained in any cycle.

4. For any edge e of a graph G, $\beta_0(G) + 1 \geq \beta_0(G - e) \geq \beta_0(G)$.

5. For any vertex v of a graph G, $\beta_0(G - v) \geq \beta_0(G)$; however, $\beta_0(G - v)$ may be arbitrarily greater than $\beta_0(G)$.

6. Let G be a 2-connected graph. Then for any two vertices, there is a cycle containing those vertices.

7. Let G be a 2-connected graph. Then for any two edges, there is a cycle containing those edges.

8. The following statements are equivalent for a connected graph G with at least three vertices:

- G is nonseparable;
- every pair of vertices lies on a cycle;
- every pair of edges lies on a cycle;
- given any three vertices u, v, and w, there is a path from u to w containing v;
- given any three vertices u, v, and w, there is a path from u to w not containing v.

9. *Menger's theorem (for vertex connectivity)*: A graph with at least $k+1$ vertices is k-connected if and only if every pair of vertices is joined by k paths which are internally disjoint (i.e., disjoint except for their origin and terminus). (Menger, 1927)

10. *Menger's theorem (for edge connectivity)*: A graph is k-edge-connected if and only if every pair of vertices is joined by k edge-disjoint paths. (Ford and Fulkerson, 1956; also Elias, Feinstein, and Shannon, 1956)

11. For any graph G, the vertex connectivity is no more than the edge connectivity, and the edge connectivity is no more than the minimum degree. That is, $\kappa(G) \leq \kappa'(G) \leq \delta(G)$, where $\delta(G)$ denotes the minimum degree.

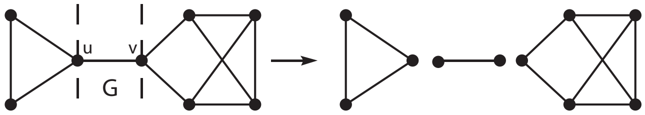
12. Furthermore, for any positive integers $a \geq b \geq c$, there exists a simple graph G for which $\delta(G) = a$, $\kappa'(G) = b$, and $\kappa(G) = c$. (Chartrand and Harary, 1968)

13. The following table gives the vertex connectivity and edge connectivity of some families of graphs.

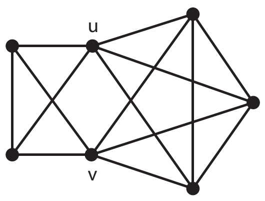
graph	κ	κ'
complete graph K_n	$n-1$	$n-1$
complete bipartite graph $K_{m,n}$	$\min(m,n)$	$\min(m,n)$
cycle graph C_n	2	2
wheel W_n	3	3
hypercube Q_n	n	n

Examples:

1. The following graph G has cut-vertices u and v. The blocks are illustrated at the right.



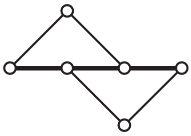
2. In the following graph, vertices u and v form a disconnecting set.



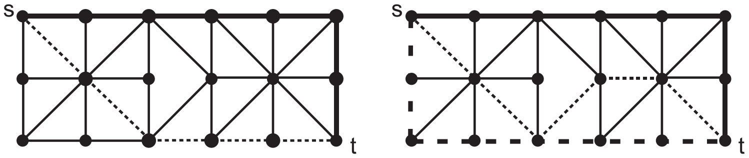
3. *Communication networks*: A communication network can be modeled as a graph with vertices representing the nodes and with undirected edges representing direct two-way communications links between nodes. In order that all pairs of nodes be in communication, the graph must be connected. Vertex connectivity and edge connectivity are measures of network reliability.

4. *Transportation networks*: Low connectivity in transportation networks results in "bottlenecks", in which many different shipments must all pass through a small number of nodes. High connectivity implies (by Menger's theorem) several alternative routes between nodes.

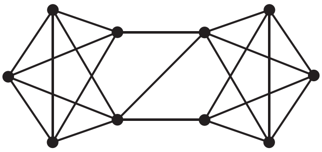
5. Menger's theorem implies that a 2-connected graph has two disjoint paths between each pair of vertices. It does *not* imply that for any path between two vertices, there must be a second such path disjoint from the first, as indicated in the following graph. There are two disjoint paths from the leftmost vertex to the rightmost, but there is no such path disjoint from the one indicated by thick edges.



6. The following shows a graph G with $\kappa(G) = 2$ and $\kappa'(G) = 3$. On the left there are two internally-disjoint paths between the upper-left vertex and the lower-right vertex, and on the right there are three edge-disjoint paths.



7. The following graph illustrates Fact 12, with $\kappa = 2$, $\kappa' = 3$, $\delta = 4$.



8.4.3 EULER TRAILS AND TOURS

Definitions:

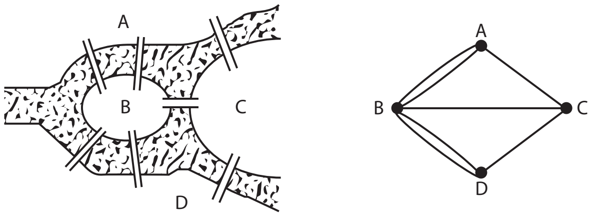
An ***Euler trail*** in a graph [digraph] is a trail that contains all the edges [arcs] of the graph.

An ***Euler tour*** or ***Euler circuit*** in a graph or digraph is a closed Euler trail.

A graph or digraph is ***Eulerian*** if it has an Euler tour.

Facts:

1. *Seven bridges of Königsberg problem*: In Kaliningrad, Russia, two branches of the River Pregel meet and flow past an island into the Baltic Sea. In 1736, when this was the town of Königsberg in East Prussia, there were seven bridges joining the banks of the river, the headland, and the island, as illustrated at the left in the following picture. The celebrated Swiss mathematician Leonhard Euler (1707–1783) was asked whether it was possible to cross all seven bridges without recrossing any of them. In the earliest known paper on graph theory, Euler proved it is impossible, because the graph at the right has no Euler trail.



2. Euler's work on the seven bridges of Königsberg problem is commonly described as the founding of graph theory and also as the founding of topology.

3. A connected graph is Eulerian if and only if every vertex has even degree. The tour may begin/end at any vertex.

4. A connected digraph has a directed Euler tour if and only if the in-degree of every vertex v equals its out-degree.

5. A connected graph has an Euler trail between distinct vertices u and v if and only if u and v are the only vertices of odd degree.

6. A connected graph (digraph) is Eulerian if and only if there exists a collection of cycles (directed cycles) whose edges partition the edge set of the graph.

7. A connected planar (see §8.7.1) graph is Eulerian if and only if its dual (see §8.8.2) is bipartite.

8. A graph G can be oriented to have a directed Euler tour if and only if it is an Eulerian graph. (Traversing an Euler tour provides an orientation.)

9. The following table indicates which members of several families of graphs are Eulerian.

graph	*Eulerian?*
bouquet B_n	for all n
dipole D_n	for even n
complete graph K_n	for odd n
complete bipartite graph $K_{m,n}$	for m and n both even
cycle graph C_n	for all n
wheel W_n	never
hypercube Q_n	for even n
tree	only if trivial

10. Algorithm 1 gives a recursive method for finding an Eulerian tour on an Eulerian graph.

Algorithm 1: **Recursive algorithm for finding an Eulerian tour.**

```
input: a connected graph $G$, all of whose vertices have even degree
output: an Euler tour of $G$

$C :=$ a cycle in the graph $G$; place $C$ on the cycle-queue $\mathcal{Q}$
partition the edge-complement $G - E(C)$ into components $H_1, H_2, \ldots, H_k$
recursively run this algorithm on each component $H_i$
{So far, $E_G$ has been completely partitioned into the cycles on $\mathcal{Q}$}
merge the elements of $\mathcal{Q}$ into an Euler tour for $G$, by traversing the cycle $C$
    and splicing in the tours found for the components $H_i$ whenever possible
```

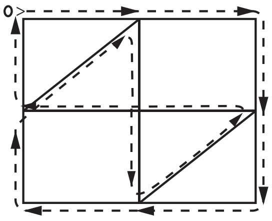
11. Fleury's algorithm for finding an Euler tour or trail is given in Algorithm 2.

Algorithm 2: **Fleury's algorithm for finding an Euler tour/trail.**

```
input: a connected graph $G$, an initial vertex $v$, and a final vertex $w$; if $v \neq w$,
   then every vertex except $v$ and $w$ must have even degree (if $v = w$, then all
   degrees must be even)
output: an Euler trail whose origin is $v$ and whose terminus is $w$
{Find trail edge with origin $v$}
if $\deg(v) > 1$ then $e :=$ any edge incident at $v$ which is not a cut-edge
else { $\deg(v) = 1$ }
   $e :=$ the unique edge incident at $v$
   $u :=$ the other endpoint of $e$
recursively find an Euler trail from $u$ to $w$ in $G - e$
prepend the edge $e$ to the trail found in the recursive step
{This yields the required Euler trail of $G$}
```

Examples:

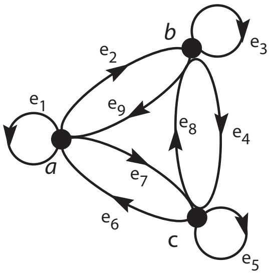
1. The following is an Eulerian graph and one of its Euler tours.



2. *Chinese postman problem* (due to Guan Meigu, 1962): A letter carrier begins at the post office, traverses every street in his territory at least once, and then returns to the post office. His objective is to walk as little as possible. Each edge of a graph representing the street configuration is labeled with the length of the corresponding block. If the graph is Eulerian, then an Euler tour gives an optimal solution. Otherwise, some edges must be retraced. Polynomial-time algorithms to solve this problem are known. See §10.2.3.

3. For every letter in an arbitrary n-letter alphabet $\mathcal{A}$, there is a string starting and ending with that letter, in which every possible substring of two letters appears consecutively exactly once. To see this, consider the digraph D with the letters of $\mathcal{A}$ as vertices and one arc for each ordered pair. (This is called a de Bruijn digraph.) The digraph D is connected and, at each of the n vertices, in-degree = out-degree = n, which implies that it is Eulerian. Thus, the sequence of vertices encountered on a closed Euler tour from any vertex to itself yields the specified string.

In the following figure, $e_1, e_2, \ldots, e_9$ are the arcs of an Euler cycle and the associated string is the sequence of vertices, *aabbccacba*. This result generalizes to substrings of any fixed length, also using Euler tours.



8.4.4 HAMILTON CYCLES AND PATHS

Definitions:

A ***Hamilton cycle*** in a graph [digraph] is a cycle [directed cycle] that includes all vertices of the graph.

A graph or digraph is ***Hamiltonian*** if it contains a Hamilton cycle.

A ***Hamilton path*** in a graph [digraph] is a path [directed path] that includes all vertices of the graph.

A ***theta graph*** is a subdivision of the complete bipartite graph $K_{2,3}$. Thus, the graph comprises three internally disjoint paths joining the two degree-3 vertices.

A ***Gray code*** is a cyclic ordering of all 2^k length-k bitstrings, such that each bitstring differs from the next in exactly one bit entry.

A ***1-tough*** (or simply ***tough***) graph is a connected graph G such that no matter what nonempty, proper vertex subset S is removed, the resulting number of components of $G - S$ is no more than $|S|$.

Facts:

1. The concept of a Hamilton cycle first arose in a puzzle within the Icosian Game, invented by Sir William Rowan Hamilton (1805–1865), an Irish mathematician. This puzzle involved a dodecahedron whose 20 vertices were labeled with world capitals. It required finding a complete tour of these 20 capitals.

2. The recognition problem for Hamiltonian graphs is NP-complete. Thus, unlike the case with Eulerian graphs, there is no easy test to decide whether a graph is Hamiltonian (unless P = NP). However, many of the following facts provide criteria that are often helpful in deciding.

3. A Hamiltonian graph has no cut-point. (Thus, it is 2-connected.)

4. The previous fact has this generalization: Let G be a Hamiltonian graph and let $S \subseteq V_G$. Then the graph $G - S$ has at most $|S|$ components. That is, Hamiltonian graphs are tough.

5. Bipartite Hamiltonian graphs have an equal number of vertices in the two parts of the bipartition.

6. If a simple graph has $n \geq 3$ vertices and minimum degree at least $n/2$, then it is Hamiltonian. (Dirac, 1952)

7. If a simple graph has $n \geq 3$ vertices, and if every pair of nonadjacent vertices u and v satisfies the inequality $\deg(u) + \deg(v) \geq n$, then it is Hamiltonian. (Ore, 1960)

8. Suppose that a simple graph with $n \geq 3$ vertices has degree sequence $d_1 \leq d_2 \leq \cdots \leq d_n$, and that for every i with $1 \leq i \leq n/2$ either $d_i > i$ or $d_{n-i} \geq n - i$. Then the graph is Hamiltonian.

9. Every simple graph with $n \geq 3$ vertices and at least $(n^2 - 3n + 6)/2$ edges is Hamiltonian.

10. Every graph with at least three vertices whose connectivity (κ) is at least as large as its independence number (α) is a Hamiltonian graph.

11. Every 4-connected planar graph is Hamiltonian.

12. If the edges of the complete graph K_n are assigned directions, then the resulting digraph always has a Hamilton directed path.

13. The edges of the complete graph K_{2n+1} can be partitioned into n Hamilton cycles.

14. Theta graphs are non-Hamiltonian and every non-Hamiltonian graph contains a theta subgraph.

15. A graph G is non-Hamiltonian if there is an independent set containing more than half the vertices of G.

16. "Almost all" graphs are Hamiltonian. That is, of the exactly $2^{n(n-1)/2}$ simple graphs on n (labeled) vertices, the proportion that are Hamiltonian tends to 1 as $n \to \infty$.

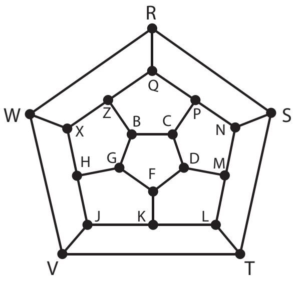
17. Suppose that a simple graph is constructed by the following process: start with n vertices and no edges; until the minimum degree is 2, a possible edge is chosen uniformly at random from among the edges not already in the graph, and added to the graph. With probability tending to 1 as $n \to \infty$, the resulting graph is Hamiltonian.

18. The following table indicates which members of several families of graphs are Hamiltonian.

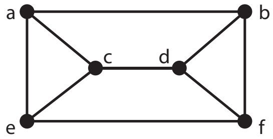
graph	*Hamiltonian?*
bouquet B_n	for all $n \geq 1$
dipole D_n	for all $n \geq 2$
complete graph K_n	for all $n \geq 3$
complete bipartite graph $K_{m,n}$	when $m = n$
cycle graph C_n	for all $n \geq 1$
wheel W_n	for all $n \geq 2$
hypercube Q_n	for all $n \geq 2$

Examples:

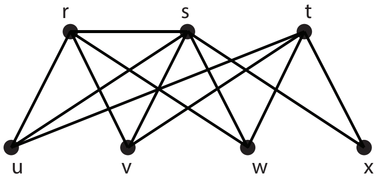
1. Finding a Hamilton cycle in the dodecahedral graph (see §8.1.3), as illustrated below, is equivalent to solving Hamilton's Icosian Game puzzle. An example of a Hamilton cycle in this graph is: $RSTVWXHJKLMNPCDFGBZQR$.



2. The following graph has the Hamilton cycle *acefdba*.



3. The following graph is non-Hamiltonian, by Fact 15, since the vertices u, v, w, and x form an independent set.

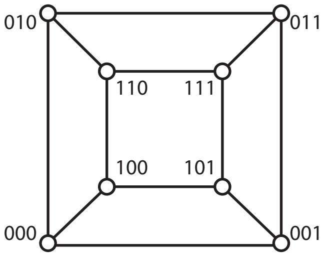


4. The 10-cycle C_{10} (§8.1.3) is an example of a graph that satisfies none of the sufficient conditions in Facts 6–10 above for Hamiltonicity, but is nonetheless Hamiltonian.

5. The traveling salesman problem (see §10.7.1) is to find a minimum-cost Hamilton cycle in a complete graph whose edges are labeled with costs.

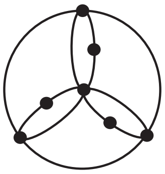
6. *Information theory — Gray codes*: In information theory, a cyclic ordering of the 2^n length-n bitstrings such that each bitstring differs from its predecessor in exactly one bit is called a *Gray code*. This corresponds to a Hamilton cycle in the n-dimensional hypercube Q_n.

The following figure shows a Hamilton cycle in the 3-cube giving the Gray code 000 → 001 → 011 → 111 → 101 → 100 → 110 → 010 → 000.



7. The Petersen graph (see §8.1.3) is tough but not Hamiltonian.

8. The following graph is tough but not Hamiltonian.



8.4.5 MATCHINGS AND FACTORS

Definitions:

A ***matching*** in a graph is a set of disjoint edges.

A ***perfect*** matching (or ***1-factor***) is a matching which covers all the vertices of the graph.

A graph H is a ***factor*** of a graph G if H is a spanning subgraph of G.

A factor which is k-regular is called a ***k-factor***.

If f is a function on $V(G)$, then a spanning subgraph H is called an ***f-factor*** if $\deg_H(v) = f(v)$, for all $v \in V(G)$. Of course, if $f(v) = k$ for every vertex, then f is just a k-factor.

An ***[a, b]-factor*** of a graph G is an f-factor such that $a \leq f(v) \leq b$, for all $v \in V(G)$.

If f and g are functions on $V(G)$, then a ***(g, f)-factor*** is a spanning subgraph H such that $g(v) \leq \deg_H(v) \leq f(v)$, for all $v \in V(G)$.

A ***path factor*** is a spanning subgraph where each component is a path.

An ***F-factor*** is a spanning subgraph where each component is either a K_2 or an odd cycle.

A ***1-factorization*** of a graph is a partition of the edges into edge-disjoint 1-factors.

A graph has the ***odd-cycle property*** if every pair of odd cycles either has a common vertex or is joined by an edge.

A graph G is ***k-tough*** if $c(G - S) \leq |S|/k$ for all cutsets $S \subseteq V(G)$, where $c(G - S)$ denotes the number of components of $G - S$.

Facts:

1. *Petersen's theorem*: A 3-regular graph with at most one cut-edge contains a 1-factor and hence also a 2-factor. (J. Petersen, 1891)

2. If $\nu(G)$ is the size of a largest matching in G and $\tau(G)$ is the minimum number of vertices necessary to cover all the edges of G, then $\nu(G) \leq \tau(G)$. *König's theorem* says that if G is bipartite, $\nu(G) = \tau(G)$. (D. König, 1931)

3. *Hall's theorem*: Let G be a bipartite graph with vertex partition $V(G) = A \cup B$. Then G has a matching of A onto B if and only if (i) $|A| = |B|$, and (ii) $|N(X)| \geq |X|$ for all $X \subseteq A$, where $N(X)$ denotes the neighborhood of set X. (In fact, Hall's and König's theorems are equivalent.) (P. Hall, 1935)

4. *Tutte's 1-factor theorem*: A graph G has a 1-factor if and only if for each $S \subseteq V(G)$, it holds that $c_o(G - S) \leq |S|$, where $c_o(G - S)$ denotes the number of odd components of $G - S$. (W. Tutte, 1947)

5. If a graph of even order is r-regular and has the odd-cycle property, then it has a 1-factor.

6. If G is k-connected and contains a 1-factor and if $|V(G)|$ is sufficiently large, then G has at least $k!$ 1-factors.

7. If G is connected and has a unique 1-factor, then G has a cut-edge belonging to this 1-factor.

8. If G is an r-regular $(r-1)$-edge-connected graph of even order, then G has a 1-factor not containing any $r-1$ prescribed edges. (And hence G has a 1-factor containing any prescribed edge.)

9. If G is a connected graph of even order whose automorphism group acts transitively on $V(G)$, then G has a 1-factor containing any given edge.

10. A 3-regular graph has exponentially many 1-factors.

11. Counting the number of perfect matchings has applications in crystal physics and organic chemistry.

12. The first polynomial-time algorithm for matching in an arbitrary graph was formulated by Edmonds [Ed65] and is now called the *Blossom Algorithm.* (See §10.2.3.)

13. Currently the fastest algorithm for matching in an arbitrary graph with n vertices and m edges is $O(m\sqrt{n})$.

14. If a graph G of order n is k-tough and kn is even, then G has a k-factor.

15. Let G be a connected graph of order n and let k be an integer ≥ 3 such that kn is even and $n \geq 4k-3$. If $d(u) \geq k$ for all vertices, and $\max\{d(u), d(v)\} \geq n/2$ for all pairs of non-adjacent vertices u and v, then G has a k-factor.

16. Let G be a graph with the odd-cycle property and with a k-factor, and let r be an integer, $1 \leq r \leq k$. Then G has an r-factor if $r|V(G)|$ is even.

17. If G is a graph and $G-v$ has a k-factor for all $v \in V(G)$, then G also has a k-factor.

18. Tutte's f-factor theorem: Graph G has an f-factor if and only if the following two conditions hold for all disjoint sets $D, S \subseteq V(G)$:

(i) $f(D) - f(S) + d_{G-D}(S) - q_G(D,S,f) \geq 0$, where $q_G(D,S,f)$ denotes the number of components C of $G-(D \cup S)$ such that $e_G(V(C), S) + f(V(C))$ is odd;

(ii) $f(D) - f(S) + d_{G-D}(S) - q_G(D,S,f) \equiv f(V(G)) \pmod 2$.

(Here $e_G(A,B)$ denotes the number of edges in G joining vertex sets A and B.)

19. If G is r-regular, then G has a $[k, k+1]$-factor, for all $k, 0 \leq k \leq r$.

20. The graph G has a (g,f)-factor if and only if both the following conditions hold:

(i) $e_G(V(C), S) + f(V(C))$ is odd;

(ii) $f(D) - g(S) + \deg_{G-D}(S) - \hat{q}_G(D,S,g,f) \geq 0$, for all pairs of disjoint sets $D, S \subseteq V(G)$, where $\hat{q}_G(D,S,g,f)$ denotes the number of components C of $G-(D \cup S)$ having $g(v) = f(v)$ for all $v \in V(C)$.

21. If G is a simple graph, then G has a path factor if and only if $i(G-S) \leq |2S|$, for all $S \subseteq V(G)$. Here $i(G-S)$ denotes the number of isolated vertices in $G-S$.

22. Let $FACT(H)$ denote the problem of finding a factor where each component is isomorphic to H. If $H = K_2$, then $FACT(H)$ is just the problem of finding a perfect matching and hence is polynomial-time. However, if H has a component with at least three vertices, then $FACT(H)$ becomes NP-complete.

23. A graph G has an F-factor if and only if $|N(S)| \geq |S|$, for every independent set $S \subseteq V(G)$. (This result can be viewed as a generalization of Hall's Theorem to the non-bipartite case.)

24. There is a polynomial-time algorithm for finding an F-factor or showing that none exists.

25. 1-*factorization conjecture*: Every r-regular graph of even order n with $r \geq n/2$ admits a 1-factorization. (Or stated differently, all such graphs have *edge chromatic number* r.)

26. The 1-factorization conjecture is "asymptotically true" in that every r-regular graph of even order n with $r \geq (\frac{1}{2} + o(1))n$ has a 1-factorization.

8.5 GRAPH ISOMORPHISM AND RECONSTRUCTION

Deciding whether two graph descriptions actually specify structurally identical graphs is called isomorphism testing. Polynomial-time algorithms for isomorphism testing are known only for certain special classes of graphs. However, there are heuristic algorithms to test isomorphism of reasonable-sized graphs. The related problem of reconstructing a graph from its vertex-deleted subgraphs is also still unsettled.

8.5.1 ISOMORPHISM INVARIANTS

Definitions:

An ***isomorphism*** between two *simple graphs* G and H is a bijection $f\colon V_G \to V_H$ between their vertex sets that preserves adjacency: $(u, v) \in E_G$ if and only if $(f(u), f(v)) \in E_H$, for any pair of vertices $u, v \in V_G$.

In full generality, a ***graph isomorphism*** between two graphs G and H is a pair of bijections $f_V\colon V_G \to V_H$ and $f_E\colon E_G \to E_H$ such that for every edge $e \in E_G$, the endvertices of e are mapped by f_V onto the endvertices of $f_E(e)$. *Note*: Except when confusion will result, the same notation f can be used for both f_V and f_E.

A ***digraph isomorphism*** is an isomorphism that preserves all arcs.

Two graphs are ***isomorphic*** if there is an isomorphism from one to the other.

The ***isomorphism type*** of a graph (digraph) G is the class of all graphs (digraphs) isomorphic to G.

A ***graph invariant*** is a property of graphs such that two isomorphic graphs have the same value with regard to it.

A ***vertex invariant*** is a property of a vertex that is preserved by isomorphism: if $f\colon V_G \to V_H$ is an isomorphism, $v \in V_G$ and p is a property of v, then the vertex $f(v) \in V_H$ has the same value as v with regard to p.

An ***automorphism*** is an isomorphism from a graph to itself.

The set of all automorphisms of a graph G forms a group under composition called the ***automorphism group*** $Aut(G)$. (See §5.2.2.)

Facts:

1. Two graphs G and H are isomorphic if there is a bijection $f\colon V_G \to V_H$ such that for every vertex pair $u, v \in V_G$ the number of edges joining u and v equals the number joining their images $f(u), f(v) \in V_H$.

2. Graph invariants are used to distinguish between nonisomorphic graphs.

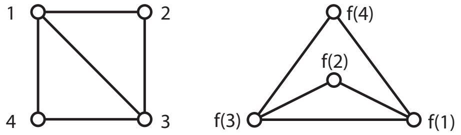
3. Most graph invariants are either too hard to compute or not strong enough at distinguishing similar but nonisomorphic graphs.

4. Vertex invariants are often used to partition the vertices of a graph into equivalence classes under graph automorphism, in order to discover the automorphism group of the graph.

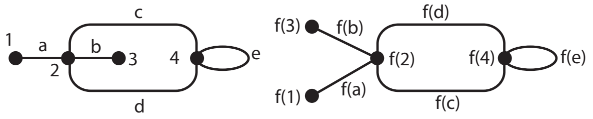
5. Graphs have many isomorphism invariants, including: elementary invariants (such as the degree sequence), structural invariants (such as the girth), topological invariants (such as genus), chromatic invariants (such as the edge chromatic number), and algebraic invariants (such as eigenvalues).

Examples:

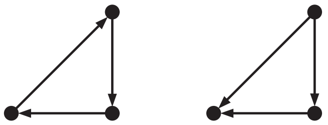
1. The following figure illustrates an isomorphism f of simple graphs.



2. The following figure illustrates an isomorphism f of nonsimple graphs.



3. The following two digraphs are not isomorphic. Even though there are six different isomorphisms of their underlying graphs, none of them preserves the direction of all the edges.



4. The next three graph drawings all look different. The following table shows some of their isomorphism invariants, from which it may be concluded that graph B cannot be isomorphic to either graph A or graph C, but that A and C might be isomorphic.

	A	B	C
# vertices	6	6	6
# edges	9	9	9
degree seq.	3, 3, 3, 3, 3, 3	3, 3, 3, 3, 3, 3	3, 3, 3, 3, 3, 3
connectivity	3	3	3
girth	4	3	4
genus	1	0	1
chromatic #	2	3	2

To construct an isomorphism between graphs A and C, assign labels 0, 1, 2, 3, 4, 5 cyclically to the vertices of A. Then assign labels 0, 2, and 4 to the top three vertices of C, and 1, 3, and 5 to the bottom three.

8.5.2 ISOMORPHISM TESTING

Definitions:

An ***isomorphism test for graphs*** is an algorithm that accepts two graphs as input and outputs "yes" to indicate the decision that they are isomorphic or "no" to indicate that they are not isomorphic. Unless the context explicitly mentions the possibility of error, it is implicitly understood that the decision is correct.

The ***eigenvalues*** of a graph are the eigenvalues of its adjacency matrix. (See §8.10.2 and §6.5.)

The ***average genus*** of a graph is the average genus of the imbedding surface, taken over all cellular imbeddings of that graph. (See §8.8.3.)

An ***equitable partition*** for a graph G is a partition $V_1, \ldots, V_n$ of its vertex set and a set of numbers $\{d_{i,j} \mid 1 \leq i, j \leq n\}$ such that every vertex in V_i is adjacent to exactly $d_{i,j}$ vertices in V_j.

A ***devil's pair*** for an isomorphism-testing approach is a pair of nonisomorphic graphs that the approach fails to distinguish.

Facts:

1. No polynomial-time isomorphism testing algorithm is known. Moreover, it is not known whether isomorphism testing is an NP-complete problem.

2. Any two randomly selected graphs are almost always not isomorphic.

3. An algorithm that calculates the order of the automorphism group of a graph can be used as a subprogram to test isomorphism of two graphs G and H, as follows:

```
if $|Aut(G)| \neq |Aut(H)|$ then $G$ and $H$ are not isomorphic
else
  if $|Aut(G \cup H)| = 2|Aut(G)|^2$ then $G$ and $H$ are isomorphic
  else $G$ and $H$ are not isomorphic
```

Note that the converse is true. Thus the problem of graph isomorphism and the problem of computing the order of the automorphism group of a graph are computationally equivalent.

4. Another algebraic approach to isomorphism testing is based on eigenvalues. A devil's pair for simply comparing eigenvalues appears in Example 4.

5. One topological approach to isomorphism testing dissects each graph into planar components (§8.7) and combines known efficient tests for isomorphism of planar graphs with careful study of possible interconnections.

6. Another topological approach to isomorphism testing is based on the genus distribution (§8.8.4), taken over all cellular imbeddings. Although calculating the genus distribution by brute force would be tedious, one can estimate it by random sampling. Any pair of trees is a trivial devil's pair, but trees are easily tested by another isomorphism algorithm.

7. The best known practical isomorphism algorithm is “NAUTY” (an acronym for No AUTomorphisms, Yes?) created by B. D. McKay. This backtrack algorithm repeatedly refines an initial vertex partition. At each stage of the refinement, a cell of size greater than 1 is broken into two parts, one a single vertex, and the coarsest equitable partition is found. The discrete partitions generated in this way correspond to labelings of the graph, organized so as to determine the automorphism group. An isomorphism invariant criterion is used to pick one of these labelings as the “canonical” one used for isomorphism testing. This algorithm can very quickly check isomorphism for most graphs.

8. To certify that two graphs are isomorphic, one can give a vertex bijection that realizes the isomorphism. Deciding whether a bijection between the vertex sets of two graphs is the vertex function of a graph isomorphism can be achieved in polynomial time.

9. If graph isomorphism is NP-complete, then the complexity hierarchy between P and NP collapses, which is considered unlikely. (See §17.5.)

10. The following table shows the best known time bounds for checking isomorphism in various classes of graphs. Almost all of these bounds have been achieved using an algebraic approach.

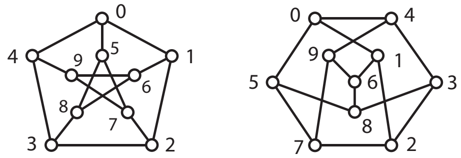
class of graphs (on n vertices)	*time bound*
graphs	$\exp O((\log n)^c)$
trees	$O(n)$
planar graphs	$O(n)$
graphs of genus g	$n^{O(g)}$
cubic graphs	$O(n^3 \log n)$
graphs with max degree $\leq d$	$n^{O(d)}$
tournaments	$n^{O(\log n)}$

11. Algorithm 1 gives a naive $O(n^2\, n!)$ method for testing whether or not two graphs are isomorphic.

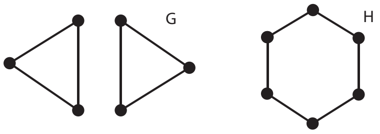
```
Algorithm 1: Naive graph isomorphism-testing algorithm.
  input: simple graphs $G, H$
  if $|V_G| \neq |V_H|$ or $|E_G| \neq |E_H|$ then print “NO” and stop
  for each bijection $f\colon V_G \to V_H$
    for each pair $u, v \in V_G$
      if $u, v$ adjacent and $f(u), f(v)$ not adjacent then print “NO” and stop
      if $u, v$ not adjacent and $f(u), f(v)$ adjacent then print “NO” and stop
  print “YES” and stop
```

Examples:

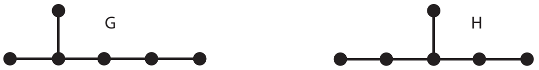
1. The labeling of the following two isomorphic graphs indicates the correspondence between vertices. This is the Petersen graph.



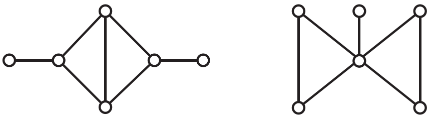
2. One devil's pair for isomorphism testing by degree sequence is



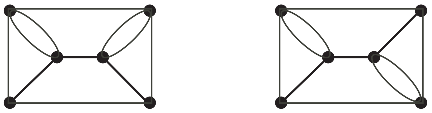
3. Another devil's pair for isomorphism testing by degree sequence is



4. The following graphs are a devil's pair for isomorphism testing by simple comparison of eigenvalues. They both have characteristic polynomial $\lambda^6 - 7\lambda^4 - 4\lambda^3 + 7\lambda^2 + 4\lambda - 1$. Yet they cannot be isomorphic because their degree sequences are different.



5. A 3-connected devil's pair for simply comparing average genus is shown below. Both graphs shown have 8 imbeddings of genus 0, 536 of genus 1, 3416 of genus 2, and 1224 of genus 3.



8.5.3 GRAPH RECONSTRUCTION

The question of whether a graph is reconstructible from its subgraphs is one of the most beguiling unsolved problems in graph theory.

Definitions:

A ***vertex-deleted subgraph*** of a graph G is a subgraph $G - v$ obtained by removing a single vertex v and all of its incident edges.

An ***edge-deleted subgraph*** of a graph G is a subgraph $G - e$ obtained by removing a single edge e.

The ***vertex-deleted subgraph collection*** of a graph G is the multi-set of all vertex-deleted subgraphs $G - v$. The number of times a graph appears in the collection equals the number of different vertices whose removal yields that graph. Thus, the cardinality of the collection equals the number of vertices of G.

The ***edge-deleted subgraph collection*** of a graph G is the multi-set of all edge-deleted subgraphs $G-e$. The number of times a graph appears in the collection equals the number of different edges whose removal yields that graph. Thus, the cardinality of the collection equals the number of edges of G.

A ***reconstructible*** graph is a graph G such that no other graph has the same vertex-deleted subgraph collection as G.

An ***edge-reconstructible*** graph is a graph G such that no other graph has the same edge-deleted subgraph collection as G.

A ***reconstructible invariant*** is a graph invariant such that all graphs with the same vertex-deleted subgraph collection have the same value with respect to this invariant.

An ***edge-reconstructible invariant*** is a graph invariant such that all graphs with the same edge-deleted subgraph collection have the same value with respect to this invariant.

Conjectures:

1. *The graph reconstruction conjecture* (P. Kelly and S. Ulam, 1941): Every graph with more than two vertices is reconstructible.

2. *The edge reconstruction conjecture*: Every graph with at least four edges is edge reconstructible.

3. *Halin's conjecture*: If two (possibly infinite) graphs with more than two vertices have the same vertex-deleted subgraph collection, then each graph is a subgraph of the other.

4. *Ramachandran's conjecture*: Every digraph D is reconstructible from the vertex-deleted subdigraphs $D-v$ together with the additional information consisting of the in- and out-degree of v.

Facts:

1. The graph reconstruction conjecture implies the edge reconstruction conjecture, and both are implied by Halin's conjecture.

2. The graph reconstruction conjecture does not hold for graphs on two vertices, because K_2 and $\overline{K_2}$ have identical sets of deleted subgraphs.

3. The edge reconstruction conjecture does not hold for graphs on four edges, because K_3+K_1 (disjoint union) and $K_{1,3}$ have identical collections of edge-deleted subgraphs.

4. Computer search has verified the reconstruction conjecture for graphs with eleven or fewer vertices.

5. The following table lists some invariants and types of graphs which are known to be reconstructible.

both edge-reconstructible and reconstructible		*other edge-reconstructible*
invariants	*graphs*	*graphs*
number of vertices	regular	more edges than non-edges
number of edges	disconnected	only two vertex degrees
degree sequence	trees	no induced $K_{1,3}$ subgraph
connectivity	outerplanar	large with Hamilton path
characteristic polynomial	cacti	$2\log_2(2 \text{ max deg}) \leq \text{avg deg}$
	maximal planar	

6. If graph F has fewer vertices than graph G, then the number of subgraphs of G isomorphic to F is reconstructible.

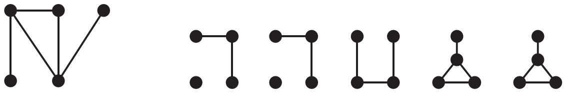
7. The reconstruction conjecture is not true for directed graphs in general, because nonreconstructible tournaments of arbitrarily large size are known, but Ramachandran's conjecture holds for all known nonreconstructible tournaments.

8. Infinite graphs are not reconstructible in general, but Halin's conjecture holds for all known nonreconstructible infinite pairs.

9. Almost every graph is uniquely determined by any three vertex-deleted subgraphs.

Example:

1. The following figure shows a graph (at the left) and its collection of vertex-deleted subgraphs.



8.6 GRAPH COLORINGS, LABELINGS, & RELATED PARAMETERS

The vertex set of a graph can be colored so that adjacent vertices are colored differently. Similarly, the edges of a graph without self-loops can be colored so that adjacent edges are colored differently. If a graph is imbedded in a surface so that there are no self-adjacent regions, then the regions can be colored so that adjacent regions receive different colors. These entertaining concepts have many important applications, including assignment and scheduling problems. We consider these and related questions here.

8.6.1 VERTEX COLORINGS

Definitions:

A (***proper***) ***vertex k-coloring*** (or ***k-coloring***) of a simple graph G is a function $f\colon V_G \to \{1,\ldots,k\}$ such that adjacent vertices are assigned different numbers. Often, the set $\{1,\ldots,k\}$ is regarded as a set of colors.

A ***coloring*** of a graph is a k-coloring for some integer k.

An ***improper coloring*** of a graph permits two adjacent vertices to be colored the same.

A graph is ***k-colorable*** (or ***k-vertex colorable***) if it has a k-coloring.

The ***chromatic number*** or (***vertex chromatic number***) $\chi(G)$ of a graph G is the minimum number k such that G is k-colorable; that is, $\chi(G)$ is the smallest number of colors needed to color the vertices of G so that no adjacent vertices have the same color.

A graph G is ***k-chromatic*** if $\chi(G) = k$.

A graph G is ***chromatically k-critical*** if G is k-chromatic and if $\chi(G-e)=k-1$ for each edge e of G.

An ***elementary contraction*** of a simple graph G on the edge e, denoted $G \cdot e$, is obtained by replacing the edge e and its two endpoints by one vertex adjacent to all the other vertices to which the endpoints were adjacent.

The ***chromatic polynomial*** of the graph G is the function $\pi_G(t)$ whose value at the integer t is the number of different functions $V_G \to \{1,\ldots,t\}$ that are proper colorings of G.

A ***list assignment*** L of a graph is an assignment of a set L_v of allowable colors at each vertex v.

A graph is ***k-choosable*** if, for every list assignment L with $|L_v| \geq k$ for all v, it is possible to choose for each vertex v an element of L_v such that the result is a proper coloring.

The ***choice number*** $ch(G)$ is the minimum k such that graph G is k-choosable.

Facts:

1. A direct way to calculate the chromatic number of a reasonably small graph is in two steps. First derive an upper bound for the number of colors needed, either by finding a coloring by trial and error or by using the greedy coloring algorithm. Then prove that one fewer colors would be insufficient. This could be achieved by an exponential-time exhaustion algorithm, or by finding an insightful proof for the particular graph.

2. $\chi(G)=2$ if and only if the graph is bipartite and its edgeset is nonempty.

3. The odd cycles are the 3-critical graphs.

4. The odd wheels W_{2n+1}, $n \geq 1$, are 4-critical.

5. $\chi(G) \leq 1+\Delta(G)$, where Δ denotes maximum degree.

6. *Brooks' theorem*: If G is a connected graph which is neither an odd cycle nor a complete graph, then $\chi(G) \leq \Delta(G)$.

7. $\chi(G) \leq 1+\max\delta(G')$, where δ denotes minimum degree, and where the maximum is taken over all induced subgraphs G' of G.

8. $\chi(G) \leq m(G)$, where $m(G)$ is the maximum length of a path in G.

9. *The Four Color Theorem* (Appel and Haken, 1976): If G is planar, then $\chi(G) \leq 4$. That is, every planar graph has a proper coloring of its vertices with 4 or fewer colors.

10. *Hadwiger's conjecture*: If G is a connected graph with $\chi(G)=n$, then K_n is a minor of G; it is known to be true for $n \leq 5$.

11. *Nordhaus-Gaddum inequalities*: If G is a graph with $|V(G)|=p$ and $\overline{G}$ is its edge-complement, then

- $2\sqrt{p} \leq \chi(G)+\chi(\overline{G}) \leq p+1$;
- $p \ \leq \chi(G)\cdot\chi(\overline{G}) \leq (p+1)^2/4$.

12. The greedy coloring algorithm (Algorithm 1) produces a vertex coloring of a graph G whose vertices are ordered. (It is called "greedy" because once a color is assigned, it is never changed.)

```
**Algorithm 1**: Greedy coloring algorithm.
  input: a graph $G$ with vertex list $v_1, v_2, \ldots, v_n$
  $c := 0$ {Initialize color at "color 0"}
  while some vertex still has no color
    $c := c + 1$ {Get the next unused color}
    for $i := 1$ to $n$ {Assign the new color to as many vertices as possible}
      if $v_i$ is uncolored and no neighbor of $v_i$ has color $c$ then assign color $c$ to $v_i$
```

13. The number of colors used by the greedy coloring algorithm depends on the ordering of the vertices of G. At least one of the orderings of the vertices of G yields $\chi(G)$, but the number of colors used can exceed $\chi(G)$ arbitrarily.

14. There is no known polynomial-time algorithm for finding $\chi(G)$ exactly. Deciding whether a graph has at most a particular chromatic number is NP-complete, if that number is at least 3.

15. The following table gives the chromatic and edge chromatic numbers (see §8.6.2) of the graphs in some common families.

graph G	$\chi(G)$	$\chi_1(G)$
path P_n, $n \geq 3$	2	2
cycle C_n, n even, $n \geq 2$	2	2
cycle C_n, n odd, $n \geq 3$	3	3
wheel W_n, n even, $n \geq 4$	3	n
wheel W_n, n odd, $n \geq 3$	4	n
complete graph K_n, n even, $n \geq 2$	n	$n-1$
complete graph K_n, n odd, $n \geq 3$	n	n
complete bipartite graph $K_{m,n}$, $m, n \geq 1$	2	$\max\{m, n\}$
bipartite G, at least one edge	2	$\Delta(G)$
Petersen graph	3	4
complete k-partite $K_{m_1,\ldots,m_k}$, $m_i \geq 1$	k	$\max\{m_1, \ldots, m_k\}$

16. The choice number is at least the chromatic number.

17. If G is connected but neither complete nor an odd cycle, $ch(G) \leq \Delta(G)$.

18. The choice number of $K_{m,m}$ is $(1 + o(1)) \log_2 m$.

19. Every planar graph is 5-choosable.

20. For every edge e of a simple graph G, $\pi_G(t) = \pi_{G-e}(t) - \pi_{G \cdot e}(t)$.

21. The chromatic polynomial $\pi_G(t)$ of a graph with n vertices and m edges is a polynomial in t of degree n, whose leading term is t^n, whose next term is $-mt^{n-1}$, and whose constant term is 0.

22. The following table gives the chromatic polynomials of some graphs.

graph	$\pi_G(t)$
n-vertex tree	$t(t-1)^{n-1}$
cycle graph C_n	$(t-1)^n + (-1)^n(t-1)$
wheel W_n	$t(t-2)^{n-1} + (-1)^{n-1}t(t-2)$
complete graph K_n	$t^{\underline{n}} = t(t-1)(t-2)\ldots(t-n+1)$

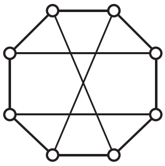
Examples:

1. *Time scheduling*: Let classes at a school be modeled by the vertices of a simple graph G, with two vertices adjacent if and only if there is at least one student in both of the corresponding classes. Then $\chi(G)$ gives the minimum number of time periods for scheduling the classes so as to accommodate all the students.

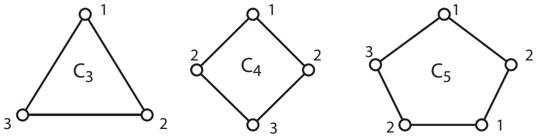
2. *Assignment of radio frequencies*: If the vertices of a graph G represent radio stations, with two stations adjacent precisely when their broadcast areas overlap, then $\chi(G)$ determines the minimum number of transmission frequencies required to avoid broadcast interference.

3. *Separating combustible chemical combinations*: Let the vertices of graph G represent different kinds of chemicals needed in some manufacturing process. An edge joins each pair of chemicals that might explode if they are combined. The chromatic number of this graph is the number of different storage areas required so that no two chemicals that mix explosively are stored together.

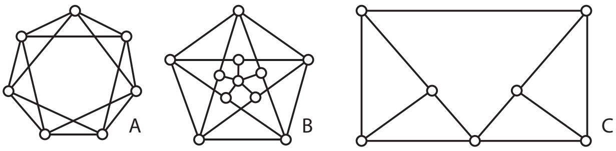
4. Proceeding in the direct way, as described in Fact 1, to color the graph in the following figure quickly yields its chromatic number. Applying the greedy coloring algorithm, with the vertices considered in cyclic order around the 8-cycle, yields a 3-coloring. Since this graph contains an odd cycle (a 5-cycle), it cannot be 2-colored. Thus, $\chi = 3$.



5. In the following figure vertex colorings are indicated for the cycle graphs C_3, C_4, and C_5; in each case three colors are used. Note that $\chi(C_3) = \chi(C_5) = 3$, whereas $\chi(C_4) = 2$ (since the vertex colored "3" could have been colored "1").



6. The following figure shows three chromatically 4-critical graphs.



7. A 3-coloring of graph A in the figure of Example 6 would necessarily give some color to three different vertices. Two of these vertices would have to be adjacent (because the edge-complement contains no 3-cycle). Thus, a 3-coloring could not be proper, and hence $\chi = 4$.

8. A 3-coloring of graph B in the figure of Example 6 would need three different colors on the outer 5-cycle. These would force the use of three different colors on the points of the central 5-star. This would force the use of a fourth color on the central vertex. Thus, $\chi = 4$.

9. The choice number of $K_{3,3}$ is 3. To see that $ch(K_{3,3}) > 2$, consider the assignment $\{a,b\}$, $\{a,c\}$, and $\{b,c\}$ to the vertices in one partite set, and the same in the other partite set.

8.6.2 EDGE COLORINGS

Definitions:

An ***edge coloring*** of a graph is an assignment of colors to its edges such that adjacent edges receive different colors.

A graph G is ***k-edge colorable*** if there is an edge coloring of G using at most k colors.

The ***edge chromatic number*** $\chi_1(G)$ (or $\chi'(G)$) of a graph G is the minimum k such that G is k-edge colorable. If $\chi_1(G) = k$, then G is ***edge k-chromatic***.

Chromatic index is a synonym for edge chromatic number.

A graph is ***edge-chromatically k-critical*** if it is edge k-chromatic and $\chi_1(G - e) = \chi_1(G) - 1$ for every edge e of G.

For a graph G, the ***line graph*** $L(G)$ has as vertices the edges of G, with two vertices adjacent in $L(G)$ if and only if the corresponding edges are adjacent in G.

Facts:

1. Every edge coloring of a graph G can be interpreted as a vertex coloring of the associated line graph $L(G)$. Thus, $\chi_1(G) = \chi(L(G))$.

2. $\Delta(G) \leq \chi_1(G)$.

3. *Vizing's theorem*: If G is a simple graph, then $\chi_1(G) \leq \Delta(G) + 1$.

4. *Vizing's general theorem*: If G is a general graph whose maximum edge multiplicity is μ, then $\chi_1(G) \leq \Delta(G) + \mu$.

5. Either $\chi_1(G) = \Delta(G)$ (G is of *class one*) or $\chi_1(G) = \Delta(G) + 1$ (G is of *class two*).

6. $\chi_1(K_{m,n}) = \chi(L(K_{m,n})) = \chi(K_m \,\square\, K_n) = \max\{m,n\}$, if $m, n \geq 1$.

7. If G is bipartite, then $\chi_1(G) = \Delta(G)$.

8. $\chi_1(K_n) = n$ if n is odd ($n \neq 1$); $\chi_1(K_n) = n - 1$ if n is even.

9. If G is planar and $\Delta(G) \geq 8$, then $\chi_1(G) = \Delta(G)$.

10. If G is 3-regular and Hamiltonian, then $\chi_1(G) = \Delta(G)$.

11. If G is regular with $|V_G|$ odd and $|E_G| > 0$, then $\chi_1(G) = \Delta(G) + 1$.

12. The greedy edge-coloring algorithm (Algorithm 2) produces an edge-coloring of a graph G, whose vertices are ordered. The number of colors it assigns depends on the vertex ordering, and it is not necessarily the minimum possible. (It is equivalent to applying the greedy vertex-coloring algorithm to the line graph.)

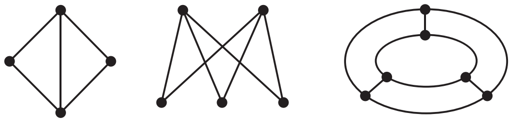
Algorithm 2: **Greedy edge-coloring algorithm.**

```
input: a graph $G$ with edge list $e_1, e_2, \ldots, e_n$
$c := 0$ {Initialize color at "color 0"}
while some edge still has no color
```

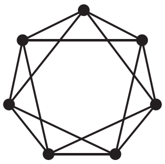
```
$c := c + 1$ {Get the next unused color}
for $i := 1$ to $n$
  {Assign the new color to as many edges as possible}
  if $e_i$ is uncolored and no neighbor of $e_i$ has color $c$ then assign color $c$ to $e_i$
```

Examples:

1. The following three graphs are all edge 3-chromatic. None of them is edge-chromatically 3-critical. Since each graph has a vertex of degree three, no 2-edge-coloring is possible.



2. The following graph is 5-edge-chromatic. Since there are 14 edges, a 4-edge-coloring would have to give the same color to four of them. For this edge-coloring to be proper, these four edges would have to have no endpoints in common. That is impossible, because the graph has only seven vertices.

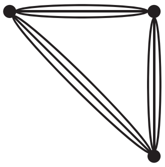


3. The Petersen graph is edge-chromatically 4-critical.

4. *Exam scheduling*: Suppose that each student at a university is to be examined orally by each of their professors at the end of the term. Then the minimum number of examination periods required is the edge chromatic number of the bipartite graph with vertices representing students and professors, and edges connecting students with their professors.

5. *Wiring electrical network boards*: A number of relays, switches, and other electronic devices $D_1, D_2, \ldots, D_n$ on a relay panel are to be connected into a network. The connecting wires are twisted into a cable, with those connected to D_1 emerging at one point, those connected to D_2 at another, and so forth. The wires emerging from the same point must be colored differently, so that they can be distinguished. The least number of colors required to color the wires is the edge chromatic number of the associated network.

6. The following nonsimple graph illustrates Vizing's general theorem. Its highest edge multiplicity is 3, its maximum degree is 6, and its edge chromatic number is 9.



8.6.3 CLIQUES AND INDEPENDENCE

Definitions:

A ***clique*** of a graph G is a complete subgraph of G. It is ***maximal*** if it is contained in no larger complete subgraph of G.

The ***clique number*** $\omega(G)$ of a graph G is the number of vertices of a largest clique of G.

A subset W of $V(G)$ (or D of $E(G)$) is ***independent*** if no two elements of W (respectively D) are adjacent.

The ***vertex independence number*** $\alpha(G)$ of G is the size of a largest independent set of vertices in G.

The ***edge independence number*** $\alpha_1(G)$ of a graph G is the size of a largest independent set of edges in G. It is also called the ***matching number***.

Facts:

1. The independence number of a graph is equal to the clique number of its edge-complement, and vice versa. That is, $\alpha(G) = \omega(\overline{G})$ and $\omega(G) = \alpha(\overline{G})$.

2. The chromatic number of a graph is at least as large as the clique number: $\chi(G) \geq \omega(G)$.

3. For each positive integer n, there is a graph G with chromatic number n and clique number equal to 2; that is, G contains no triangles.

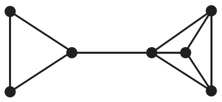
4. If no induced subgraph of a graph is isomorphic to P_4, then its chromatic number equals its clique number and the greedy algorithm (§8.6.1, Algorithm 1) always produces a coloring with the minimum number of colors.

5. $\dfrac{|V(G)|}{\alpha(G)} \leq \chi(G) \leq |V(G)| + 1 - \alpha(G)$.

6. If $|E(G)| > \Delta(G) \cdot \alpha_1(G)$, then $\chi_1(G) = \Delta(G) + 1$.

Examples:

1. The following graph has three maximal cliques—of sizes 2, 3, and 4. Thus, its clique number is 4.



2. If $1 \leq m \leq n$, then $\omega(K_{m,n}) = 2$, $\alpha(K_{m,n}) = n$, and $\alpha_1(K_{m,n}) = m$.

3. Define $K_{n(m)}$ to be the graph whose edge complement is nK_m, the disjoint union of n copies of K_m. Then $\omega(K_{n(m)}) = n$, $\alpha(K_{n(m)}) = m$, and $\alpha_1(K_{n(m)}) = \lfloor \frac{mn}{2} \rfloor$.

8.6.4 MAP COLORINGS

Definitions:

An ***orientable surface*** S is a surface homeomorphic to a sphere with $g \geq 0$ handles attached and is denoted by S_g.

A ***nonorientable surface*** S is a surface homeomorphic to a sphere with $k \geq 1$ crosscaps attached and is denoted by N_k. (See §8.8.1.)

The ***Euler characteristic*** of a surface S is $2-2g$ if S is homeomorphic to S_g, and $2-k$ if S is homeomorphic to N_k. The most usual notation for Euler characteristic in mathematics is $\chi(S)$. However, since that is used for the chromatic number, ad hoc notation such as $eu(S)$ is sometimes used in chromatic graph theory.

A ***map*** on a surface is an imbedding of a graph on that surface.

A ***map coloring*** is an assignment of colors to the regions of a map so that adjacent regions (those sharing a one-dimensional boundary portion) receive different colors.

A map M is ***n-colorable*** if there is a map coloring of M using at most n colors.

The ***chromatic number*** $\chi(M)$ of a map M is the minimum n such that M is n-colorable.

The ***chromatic number*** $\chi(S)$ of a surface S is the largest chromatic number $\chi(M)$ for all maps M on S.

The (***empire***) ***chromatic number*** $\chi(S,c)$ for a surface S is the largest $\chi(M)$ for all maps M on S, where now a country has at most $c \geq 1$ components (regions) and all components of a fixed country are colored alike, but adjacent components of different countries must receive different colors. (Thus $\chi(S)=\chi(S,1)$.)

Facts:

1. A region coloring can be regarded as a vertex coloring of the dual graph (see §8.8.2). From this perspective, χ is the largest value of $\chi(G)$ for all graphs G imbeddable on S.

2. By stereographic projection (see §8.7.5), $\chi(S_0)$ gives the chromatic number of the plane.

3. Let G be a planar cubic block; then $\chi_1(G)=3$.

4. Let M be a plane map whose graph G is connected and bridgeless. Then $\chi(M)=2$ if and only if G is Eulerian.

5. Let M be a plane map for a cubic connected bridgeless graph G; then $\chi(M)=3$ if and only if the dual graph is Eulerian.

6. If G is a plane graph without triangles, then $\chi(G)=3$. (Grötzsch, 1958)

7. *The Four Color Theorem* (Appel and Haken, 1976): $\chi(S_0)=4$. That is, every map on a sphere or plane can be colored with 4 or fewer colors.

8. *The Heawood map coloring theorem* (Ringel and Youngs, 1968): For $g>0$,

$$\chi(S_g)=\left\lfloor \frac{7+\sqrt{1+48g}}{2} \right\rfloor .$$

9. *The nonorientable Heawood map coloring theorem* (Ringel, 1954): For $k>0$,

$$\chi(N_k)=\left\lfloor \frac{7+\sqrt{1+24k}}{2} \right\rfloor$$

except that $\chi(N_2)=6$.

10. $\chi(S,c) \leq \left\lfloor \frac{6c+1+\sqrt{(6c+1)^2-24eu(S)}}{2} \right\rfloor .$

11. $\chi(S_0,c)=6c$ for $c \geq 2$; $\chi(S_1,c)=6c+1$ for $c \geq 1$; and $\chi(N_1,c)=6c$ for $c \geq 1$.

12. *History of the four color problem*: In 1852, Francis Guthrie asked whether four colors suffice to color every planar map. Arthur Cayley in 1878 was first to mention the problem in print. In 1879, A. B. Kempe, a London barrister, published a "proof" of the four color conjecture: every planar map is 4-colorable. In 1890 Percy Heawood found an error in Kempe's argument. A correct proof was established by Kenneth Appel and Wolfgang Haken in 1976.

13. *Concepts in the Haken-Appel proof of the four color theorem*: Appel and Haken found an "unavoidable" set with 1476 graphs, which means that at least one of these graphs must be a subgraph of any minimum counterexample to the four color conjecture. A method called "discharging" is used to find an unavoidable set. Using a computer, they proved that each of these graphs is "reducible", which means that it cannot be a subgraph of a minimum counterexample.

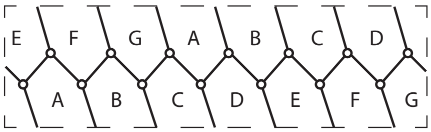
14. A simplified proof of the four color theorem can be found at the website:
`http://www.math.gatech.edu/~thomas/FC/ftpinfo.html`

Examples:

1. Let M be the tetrahedral map, i.e., an imbedding of K_4 in S_0. By Fact 4, $\chi(M) \neq 2$, since K_4 is not Eulerian. By Fact 5, $\chi(M) \neq 3$, since the dual graph (isomorphic to K_4) is also not Eulerian. Thus, $\chi(M) = 4 = \chi(S_0)$.

2. *Cartography*: If countries on Earth are allowed two components, but no more, then by Fact 11 a map might require twelve colors, but no more.

3. By Fact 8, $\chi(S_1) = 7$. The dual map of the following figure imbeds K_7 in the torus. To obtain the torus, paste the left side of the rectangular sheet directly to the right side, and then paste the top to the bottom with a $\frac{2}{7}$ twist.



8.6.5 MORE GRAPH COLORINGS

This subsection deals with the proper coloring of the vertices of a graph where each vertex is assigned more than one color (or label), or colorings of the vertices and edges simultaneously.

Definitions:

A (***proper***) ***k-tuple*** coloring of a graph is an assignment of a set of k distinct colors to each vertex of a graph so that adjacent vertices have disjoints sets.

The ***k-tuple chromatic number*** $\chi_k(G)$ of a graph G is the smallest number of colors such that G has a k-tuple coloring.

The ***fractional chromatic number*** $\chi_f(G)$ of a graph G is the minimum of the ratio $\chi_k(G)/k$ taken over all k.

A ***total coloring*** of a graph is an assignment of colors to both the vertices and edges such that two elements receive different colors if they are adjacent or incident.

The ***total chromatic number*** $\chi_T(G)$ is the minimum number of colors needed for a total coloring of graph G.

Facts:

1. $\chi_k(G) \leq k\chi(G)$.

2. If the clique number $\omega(G)$ (see §8.6.3) of G is equal to $\chi(G)$, then $\chi_k(G) = k\chi(G)$.

3. $\chi_k(K_n) = nk$.

4. If G is bipartite (with at least one edge), then $\chi_k(G) = 2k$.

5. $\chi_f(G) \leq \chi(G)$.

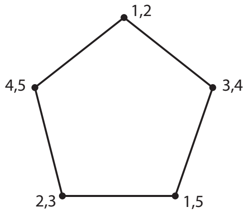
6. $\chi_T(K_n) = n$ if n is even, and $\chi_T(K_n) = n + 1$ if n is odd.

7. The *total coloring conjecture* is that $\chi_T(G) \leq \Delta(G) + 2$ for all graphs G.

Examples:

1. *Multiple channel assignment*: Several cities each need to have four broadcast frequencies assigned to them (a generalization of §8.6.1, Example 2). The 4-tuple chromatic number $\chi_4(G)$ is the minimum number of frequencies needed so that there is no broadcast interference.

2. $\chi_2(C_5) = 5$, as illustrated in the following figure. In fact it can be shown that $\chi_f(C_5) = 5/2$.



3. *Exam scheduling*: Each final exam at a school is given in two parts, with each part requiring one final exam period. If a graph G is constructed by using the courses as vertices, with an edge joining v and w if there is a student taking courses v and w, then $\chi_2(G)$ gives the minimum number of periods required to schedule all the exams so no student has a conflict.

8.6.6 DOMINATION IN GRAPHS

Domination has applications in areas such as network design, social sciences, optimization, and bioinformatics. For more information see the books [HaHeSl98a], [HaHeSl98b], and [HeYe13].

Definitions:

A ***dominating set*** of a graph is a set S of vertices such that every vertex not in S is adjacent to a vertex in S.

A ***minimal dominating set*** is a dominating set that contains no dominating set as a proper subset.

The ***domination number*** $\gamma(G)$ is the minimum cardinality of a (minimal) dominating set in a graph G, and the ***upper domination number*** $\Gamma(G)$ is the maximum cardinality of a minimal dominating set.

A ***total dominating set*** of a graph is a set S of vertices such that every vertex is adjacent to a vertex in S. Thus, a total dominating set S is a dominating set with the additional property that the subgraph induced by the set S contains no isolated vertex.

A total dominating set S is ***minimal*** if it contains no total dominating set as a proper subset.

The ***total domination number*** $\gamma_t(G)$ of a graph G is the minimum cardinality of a total dominating set, and the ***upper total domination number*** $\Gamma_t(G)$ of G is the maximum cardinality of a minimal total dominating set.

An ***independent dominating set*** is a set that is both a dominating set and an independent set.

The ***independent domination number***, $i(G)$, and the ***(vertex) independence number***, $\alpha(G)$, are the minimum and maximum cardinalities, respectively, of a maximal independent set in G.

Let S be a set of vertices in a graph G. A vertex $v \in S$ is ***S-irredundant*** if v has no neighbor in S or there exists a vertex $w \notin S$ that is adjacent to v but to no other vertex of S. The set S is an ***irredundant set*** if every vertex in it is S-irredundant.

The ***irredundance number*** of G, $ir(G)$, is the minimum cardinality of a maximal irredundant set, while the ***upper irredundance number*** of G, $IR(G)$, is the maximum cardinality of an irredundant set.

The ***corona*** $H \circ K_1$ of a graph H is the graph obtained from H by adding for each vertex v of H a new vertex v' and the pendant edge vv'.

Facts:

1. If S is a dominating set, then so too is every superset of S. However, not every subset of S is necessarily a dominating set.

2. Every maximal independent set is a minimal dominating set, and every minimal dominating set is a maximal irredundant set. Thus $ir(G) \leq \gamma(G) \leq i(G) \leq \alpha(G) \leq \Gamma(G) \leq IR(G)$.

3. Determining whether a graph has domination number at most k is NP-complete.

4. If G is a graph of order n, then $1 \leq \gamma(G) \leq n$. Equality of the lower bound is attained if and only if the maximum degree of G is $n-1$, and equality holds for the upper bound if and only if G is the empty graph, that is, a set of isolated vertices.

5. If $G = (V, E)$ is a graph with no isolated vertex and D is a minimal dominating set of G, then $V \setminus D$ is a dominating set of G.

6. *Ore's bound.* If G is a graph of order n with no isolated vertex, then $\gamma(G) \leq n/2$.

7. If G is a graph of order n with no isolated vertex, then $\gamma(G) = n/2$ if and only if the components of G are the cycle C_4 or the corona $H \circ K_1$ for any connected graph H.

8. For every regular graph G of order n with no isolated vertex, $\Gamma(G) \leq n/2$.

9. If graph G has n vertices and m edges and does not contain isolated vertices, then $\gamma(G) \leq (1-b)n/2 + bm$ for all $b \geq 0$. For example, taking $b = 0$, we have Ore's upper bound of $\gamma(G) \leq n/2$. Taking $b = 1/3$, we have that $\gamma(G) \leq (n+m)/3$.

10. If G is a connected graph of order $n \geq 8$ with $\delta(G) \geq 2$, then $\gamma(G) \leq 2n/5$, and this bound is tight. (Here $\delta(G)$ denotes the minimum degree.)

11. If G is a graph of order n and $\delta(G) \geq 3$, then $\gamma(G) \leq 3n/8$, and this bound is tight.

12. If G is a connected graph of order $n \geq 14$ with $\delta(G) \geq 2$ and no induced 4-cycle and no induced 5-cycle, then $\gamma(G) \leq 3n/8$.

13. *Vizing's conjecture.* For any graphs G and H, $\gamma(G \,\square\, H) \geq \gamma(G)\gamma(H)$. (Here $\square$ denotes Cartesian product.)

14. For any graphs G and H, $\Gamma(G \,\square\, H) \geq \Gamma(G)\Gamma(H)$.

15. If G is a connected graph of order $n \geq 3$, then $\gamma_t(G) \leq 2n/3$.

16. If G is a connected graph of order $n \geq 11$ with $\delta(G) \geq 2$, then $\gamma_t(G) \leq 4n/7$.

17. If G is a graph of order n with $\delta(G) \geq 3$, then $\gamma_t(G) \leq n/2$.

18. If G is a graph of order n with $\delta(G) \geq 4$, then $\gamma_t(G) \leq 3n/7$.

19. If G is a graph of order n with $\delta(G) \geq 5$, then $\gamma_t(G) \leq \left(\frac{4}{11} + \frac{1}{72}\right) n$. The conjectured bound is $\gamma_t(G) \leq 4n/11$.

20. If G is a graph of order n with $\delta(G) \geq 1$, then $\gamma_t(G) \leq \left(\frac{1+\ln\delta}{\delta}\right) n$.

21. If G is a connected graph of order n, girth $g \geq 3$ with $\delta(G) \geq 2$, then

$$\gamma_t(G) \leq \frac{n}{2} + \max\left(1, \frac{n}{2(g+1)}\right),$$

and this bound is sharp.

22. For every k-regular graph G of order n with no isolates, $\Gamma_t(G) \leq n/(2 - 1/k)$.

23. For any isolate-free graphs G and H, $2\gamma_t(G \,\square\, H) \geq \gamma_t(G)\gamma_t(H)$.

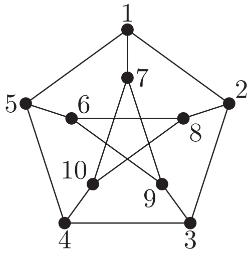
24. For any isolate-free graphs G and H, $2\Gamma_t(G \,\square\, H) \geq \Gamma_t(G)\Gamma_t(H)$.

25. For every $0 < \epsilon' < \epsilon$ and $p = (1+\epsilon')\sqrt{\frac{1}{n}(2\ln n)}$, almost every graph $G \in \mathcal{G}(n,p)$ has

$$\left(\frac{1}{2\sqrt{2}} - \epsilon\right)\sqrt{n\,\ln(n)} < \gamma(G) \leq \gamma_t(G) < \left(\frac{1}{\sqrt{2}} + \epsilon\right)\sqrt{n\,\ln(n)}.$$

Examples:

1. For the Petersen graph G below, the sets $S_1 = \{2,5,7\}$, $S_2 = \{1,3,6,10\}$, and $S_3 = \{1,2,3,4,5\}$ are all minimal dominating sets. Hence, the Petersen graph contains minimal dominating sets of cardinalities 3, 4, and 5. No set of two vertices dominates all ten vertices in the graph, and so the set S_1 is a dominating set of minimum cardinality and $\gamma(G) = 3$. Every minimal dominating set in the Petersen graph has cardinality at most 5, implying that $\Gamma(G) = 5$.



2. For the Petersen graph G above, it holds that $\gamma_t(G) = 4$ and the closed neighborhoods $N[v]$ corresponding to the ten vertices v in the Petersen graph form the ten minimum total dominating sets of G. Further, $\Gamma_t(G) = 6$ and the set $\{1,3,5,8,9,10\}$ is an example of a minimal total dominating set of G of size 6.

8.6.7 GRAPH PEBBLING

Definitions:

A ***configuration*** C is an assignment of pebbles to the vertices of a connected graph G. The value $C(v)$ denotes the number of pebbles at vertex v. The ***size*** of C is defined as $|C| = \sum_{v \in V(G)} C(v)$.

For an edge uv, if u has at least two pebbles on it, then a ***pebbling step from*** u ***to*** v is to remove two pebbles from u and place one pebble on v. That is, if C is the original configuration, then the resulting configuration C' has $C'(u) = C(u)-2$, $C'(v) = C(v)+1$, and $C'(x) = C(x)$ for all $x \in V(G) - \{u, v\}$.

A configuration C is ***r-solvable*** if it is possible from C to place a pebble on vertex r via pebbling steps; it is ***r-unsolvable*** otherwise. The configuration C is ***solvable*** if it is r-solvable for every vertex r.

For a connected graph G and a ***root*** vertex r, the ***rooted pebbling number*** $\pi(G, r)$ is defined to be the minimum number t so that every configuration C of size t is r-solvable. The ***pebbling number*** $\pi(G)$ is the maximum value of $\pi(G, r)$ over all r.

A graph G is of ***Class 0*** if $\pi(G)$ equals its order.

A sequence of paths $\mathcal{P} = (P[1], \ldots, P[h])$ is a ***maximum r-path partition*** of a rooted tree (T, r) if $\mathcal{P}$ forms a partition of $E(T)$, r is a leaf of $P[1]$ and, for all $1 \leq i \leq h$, $P[i]$ is a maximum-length path in $T - \bigcup_{j=1}^{i-1} E(P[j])$ among all such paths with one endpoint in $\bigcup_{j=1}^{i-1} P[j]$.

For $m \geq 2t+1$, the ***Kneser graph*** $K(m, t)$ has as vertices all t-element subsets of $\{1, 2, \ldots, m\}$ and edges between every pair of disjoint sets.

Facts:

1. Graph pebbling arose in combinatorial number theory. It has since produced the following more general result. If $g_1, \ldots, g_n$ is a sequence of elements of an abelian group Γ of size n, then there is a nonempty subsequence $(g_k)_{k \in K}$ such that $\sum_{k \in K} a_k = 0_\Gamma$ and $\sum_{k \in K} 1/|g_k| \leq 1$, where $|g|$ denotes the order of the element g in Γ and 0_Γ is the identity element in Γ.

2. Every rooted graph (G, r) has $\pi(G, r) \geq \max\{n(G), 2^{\text{ecc}(r)}\}$, where $\text{ecc}(r)$ is the maximum distance of a vertex from r, and $\pi(G, r) \leq 2^{n(G)-1}$.

3. The path on n vertices has pebbling number $\pi(P_n) = 2^{n-1}$.

4. The cycle has pebbling number $\pi(C_{2k}) = 2^k$ and $\pi(C_{2k+1}) = \lceil (2^{k+2} - 1)/3 \rceil$ for all $k \geq 1$.

5. If (T, r) is a rooted tree, then $\pi(T, r) = \sum_{i=1}^{h} 2^{l_i} - h + 1$, where l_i is the length of path $P[i]$ in a maximum r-path partition $\mathcal{P}$ of T.

6. Complete graphs, complete bipartite graphs other than stars, cubes, the Petersen graph, and split graphs with minimum degree at least 3 are all Class 0.

7. For any constant $c > 0$ there is an integer t_0 such that the Kneser graph $K(2t+s, t)$ is Class 0 when $t > t_0$ and $s \geq c(t/\log t)^{1/2}$.

8. If G is a graph with n vertices and e edges, then G is Class 0 when $e \geq \binom{n-1}{2} + 2$, while G being Class 0 implies that $\kappa(G) \geq 2$, $e \geq \lfloor 3n/2 \rfloor$, and the girth of G is at most $1 + 2\log n$.

9. If $\operatorname{diam}(G) = 2$, then $\pi(G) \le n(G) + 1$. If also $\kappa(G) \ge 3$, then G is Class 0.

10. If $\operatorname{diam}(G) = d$ and $\kappa(G) \ge 2^{2d+3}$, then G is Class 0.

11. There exists a Class 0 graph G on at most $n \ge 3$ vertices with girth at least $\lfloor\sqrt{(\log n)/2 + 1/4} - 1/2\rfloor$.

12. Let $G_{n,p}$ be the random graph on n vertices with edge probability p (see §8.11.3, §10.8.2). If $p \gg (n \log n)^{1/d}/n$ for fixed d, then almost surely $G_{n,p}$ is Class 0.

13. *Graham's Conjecture* states that every pair of connected graphs G and H satisfy $\pi(G \,\square\, H) \le \pi(G)\pi(H)$. This is known to be true when G and H are both complete graphs, both trees, both cycles, both complete bipartite graphs with at least 15 vertices per part, or both connected graphs on n vertices with minimum degree at least $k \ge 2^{12n/k+15}$.

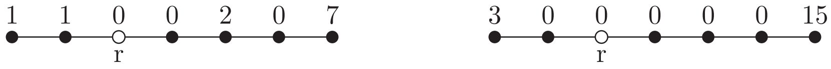
14. Deciding whether a configuration on a graph is solvable is NP-complete, even when restricted to the classes of diameter-two graphs or planar graphs, but is in P when restricted to the classes of complete graphs, trees, diameter-two planar graphs, or outerplanar graphs.

15. Deciding whether $\pi(G) \le k$ is Π_2^{P}-complete (see §17.5.1).

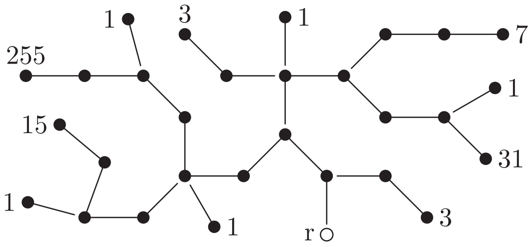
16. $\pi(G)$ can be calculated in polynomial time when G is a tree, a diameter-two graph, a split graph, or a 2-path.

Examples:

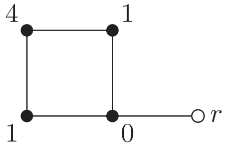
1. Two r-unsolvable configurations (of maximum size, right) on the path P_7 are shown below.



2. A maximum-sized r-unsolvable configuration on a tree is shown below.



3. An r-solvable (and solvable) configuration is shown below.



8.6.8 GRAPH LABELINGS

Definitions:

A graph with q edges is ***graceful*** if there exists an injection f from the vertices to the set $\{0, 1, \ldots, q\}$ such that, when each edge xy is assigned the label $|f(x) - f(y)|$, the resulting edge labels are distinct.

A graph with q edges is ***harmonious*** if there is an injection f from the vertices to the group of integers modulo q such that when each edge xy is assigned the label $f(x) + f(y)$ (mod q), the resulting edge labels are distinct. When a graph is a tree, exactly one label may be used on two vertices.

A connected graph is called ***magic*** if there is a labeling of the edges with distinct positive integers such that for each vertex v the sum of the labels of all edges incident with v is the same for all v. A magic labeling is called ***supermagic*** if the set of edge labels consists of consecutive positive integers.

A graph with q edges is called ***antimagic*** if its edges can be labeled with distinct integers from 1 to q such that the sums of the labels of the edges incident to each vertex are distinct.

Remarks:

1. In 1967 A. Rosa introduced graceful labelings as tools for decomposing the complete graph into isomorphic subgraphs.

2. In 1980 R. Graham and N. Sloane introduced harmonious labelings as a modular version of additive bases problems stemming from error-correcting codes.

3. Determining whether a graph has a harmonious labeling is NP-complete.

4. "Almost all" graphs are not graceful or harmonious.

5. The conjecture made in 1968 by Ringel and Kotzig that all trees are graceful is still open.

6. The conjecture made in 1980 by Graham and Sloane that all trees are harmonious is still open.

7. J. Sedláček introduced magic labelings of graphs in 1963.

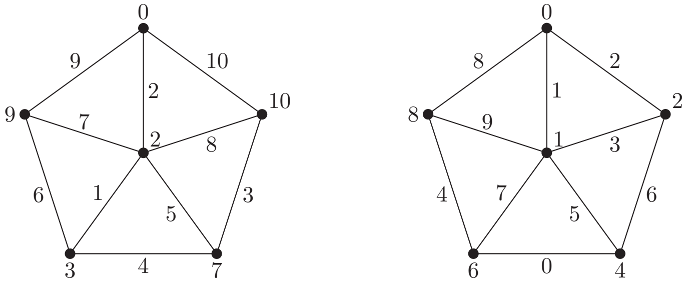
8. B. M. Stewart introduced supermagic labelings of graphs in 1967 as an extension of the classic concept of an $n \times n$ magic square in number theory, which corresponds to a supermagic labeling of $K_{n,n}$.

9. In 1990 Hartsfield and Ringel introduced antimagic graphs. Their conjectures that every tree except P_2 is magic and every connected graph except P_2 is magic are still open.

10. There are scores of variations on graceful, harmonious, magic, and antimagic labelings.

Examples:

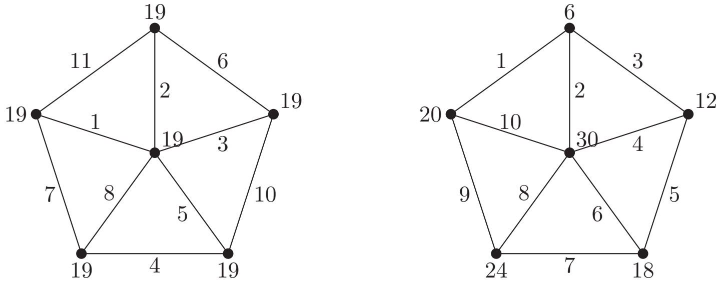
1. Here are graceful and harmonious labelings of the wheel W_5.



2. The following table specifies conditions for which some common graphs are graceful and harmonious.

Graph	*Graceful*	*Harmonious*
trees	at most 35 vertices	at most 31 vertices
caterpilars	all	all
C_n	iff $n \equiv 0, 3 \pmod 4$	iff n odd
wheels W_n	all	all
grids $P_m \square P_n$	all	iff $(m, n) \neq (2, 2)$
K_n	iff $n \leq 4$	iff $n \leq 4$
$K_{m,n}$	all	iff m or $n = 1$
$C_m \square P_n$	$n = 2$ or m even	n odd; $n = 2, m \neq 4$; $m = 4, n \geq 3$
$C_m \square C_n$	$m \equiv 0 \pmod 4$, n even	$m = 4,\ n > 1$
n-cube	all	iff $n \geq 4$

3. Here are magic and antimagic labelings of the wheel W_5.



4. The following table specifies conditions for which some common magic and antimagic graphs. An M indicates the graph is magic; SPM indicates it is supermagic.

Graph	*Magic*	*Antimagic*
P_n	M iff $n = 2$	$n \geq 3$
C_n	M none	all
K_n	M if $n = 2$ or $n \geq 5$	$n \geq 3$
wheels W_n	M $n \geq 4$	all
$K_{m,n}$	M if $m = n \geq 3$	all except $K_{1,1}$
$C_m \square C_n$	SPM if $m = n$ or m, n even	all
n-cube	SPM $n = 1$ or $n > 2$ even	all

8.7 PLANAR DRAWINGS

Planarity is an important consideration in physical networks of any kind, because it is usually less expensive to fabricate a planar network. For instance, overpasses are a costly feature in highway design. Moreover, it is less complicated to manufacture a planar electrical network than a nonplanar network.

8.7.1 CHARACTERIZING PLANAR GRAPHS

A graph cannot be drawn without edge-crossings in the plane if it "contains" either the complete graph K_5 or the complete bipartite graph $K_{3,3}$. Conversely, every graph that "contains" neither of those two graphs can be drawn without crossings.

Definitions:

A graph ***imbedding*** (or ***embedding***) is a drawing with no crossings at all.

A graph is ***planar*** if it has an imbedding in the plane.

A graph is ***nonplanar*** if no imbedding in the plane is possible.

A drawing of a graph is ***normalized*** if there are no crossings, or if each crossing is a point where the interior of one edge crosses the interior of one other edge. (Edges may be drawn either straight or with curves.)

The graphs K_5 and $K_{3,3}$ are called the ***Kuratowski graphs***.

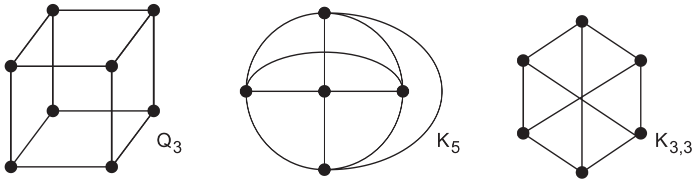
Facts:

1. The graphs K_5 and $K_{3,3}$ are both nonplanar. See Examples 4 and 5 for proofs that they are not planar.

2. *Kuratowski planarity theorem*: A graph is planar if and only if it has no subgraph homeomorphic (see §8.1.2) to K_5 or to $K_{3,3}$.

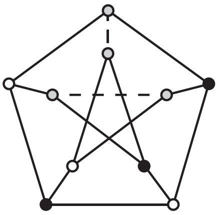
Examples:

1. The drawings of Q_3, K_5, and $K_{3,3}$ in the following figure all have crossings. However, the graph Q_3 is planar, because it can be redrawn without any crossings.

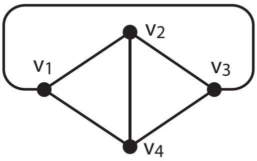


2. The drawings of Q_3 and K_5 in the figure of Example 1 are normalized, but the drawing of $K_{3,3}$ is not normalized, because three lines go through the same point.

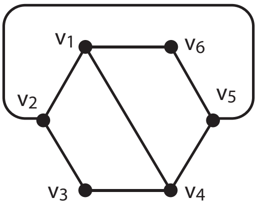
3. The Petersen graph does not contain $K_{3,3}$ itself as a subgraph. However, if the two edges depicted by broken lines in the following figure are discarded, then the resulting graph is homeomorphic to $K_{3,3}$, so the Petersen graph is not planar.



4. *Nonplanarity of K_5*: To draw the complete graph on the vertices v_1, v_2, v_3, v_4, v_5 in the plane, one might as well start by drawing the 4-cycle v_1, v_2, v_3, v_4, which (by the Jordan curve theorem) separates the plane. Next draw the edges between v_1 and v_3 and between v_2 and v_4. To avoid crossing each other, one of these edges must go inside the 4-cycle and the other outside, as shown in the following figure. The net result so far is that there are four 3-sided regions, each with three vertices on its boundary. Thus, no matter which region is to contain the vertex v_5, that vertex cannot be joined to more than three other vertices without crossing the boundary.



5. *Nonplanarity of $K_{3,3}$*: To form a planar drawing of the complete bipartite graph on the parts $\{v_1, v_3, v_5\}$ and $\{v_2, v_4, v_6\}$, one might as well start by drawing the 6-cycle $v_1, v_2, v_3, v_4, v_5, v_6$, which separates the plane. Next draw the edges between v_1 and v_4 and between v_2 and v_5. To avoid crossing each other, one of these edges must go inside the 6-cycle and the other outside. The net result so far is shown in the following figure. It is now clear that v_3 and v_6 cannot be joined without crossing some other edge.



6. *Civil engineering*: Suppose that a number of towns are to be joined by a network of highways. If the network is planar, then the cost of bridges for underpasses and overpasses can be avoided.

7. *Electrical networks*: A planar electrical network with bare wires joining the nodes can be placed directly onto a flat board. Otherwise, insulation is needed to prevent short circuits at wire crossings.

8.7.2 NUMERICAL PLANARITY CRITERIA

Certain numerical relationships are true of all planar graphs. One way to show that a graph is nonplanar is to show that it does not satisfy one of these relations.

Definitions:

A ***region*** of an imbedded graph is, informally, a piece of what results when the surface is cut open along all the edges. That is, a maximal subsurface containing no vertex and no part of any edge of the graph.

The ***boundary of a region*** R of an imbedded graph is the subgraph containing all vertices and edges incident on R. It is denoted ∂R.

A ***face*** of an imbedded graph is a region plus its boundary.

The ***exterior region*** of a planar graph drawing is the region that extends to infinity.

The ***girth*** of a graph is the number of edges in a shortest cycle. The girth is undefined if the graph has no cycles.

Facts:

1. *Euler polyhedral equation*: Let $G = (V, E)$ be a connected graph imbedded in the plane with face set F. Then $|V| - |E| + |F| = 2$.

2. *Edge-face inequality*: Let $G = (V, E)$ be a simple, connected graph imbedded in a surface with face set F. Then $2|E| \geq 3|F|$.

3. *Edge-face inequality (strong version)*: Let $G = (V, E)$ be a connected graph, but not a tree, imbedded in a surface with face set F. Then $2|E| \geq \text{girth}(G) \cdot |F|$.

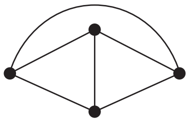
4. Let $G = (V, E)$ be a simple, connected planar graph. If G is planar then $3|V| - |E| \geq 6$.

5. Let $G = (V, E)$ be a connected planar graph that is not a tree. Then $(|V| - 2) \cdot \text{girth}(G) \geq |E| \cdot (\text{girth}(G) - 2)$.

6. Let $G = (V, E)$ be a simple, connected, bipartite graph that is not a tree. If G is planar then $|E| \leq 2 \cdot |V| - 4$.

Examples:

1. In the planar imbedding of the following figure, $|V| = 4$, $|E| = 6$, and $|F| = 4$. Thus, $|V| - |E| + |F| = 4 - 6 + 4 = 2$. (The "exterior" region counts as a face.)



2. Fact 4 implies that K_5 is nonplanar.

3. Fact 5 implies that the Petersen graph, whose girth equals 5, is nonplanar.

4. Fact 6 implies that $K_{3,3}$ is nonplanar.

8.7.3 PLANARITY ALGORITHM

Definitions:

A ***bridge B of a subgraph H*** in a graph G is a maximal connected subgraph B of the edge-complement $G - H$ such that for any two edges d and e of B, there is a path starting with d and terminating in e, none of whose internal vertices lies in $B \cap H$.

An ***attachment of a bridge*** is a vertex both in the bridge and the subgraph. (That is, an attachment is a vertex in which the bridge meets the rest of the graph.)

Facts:

1. Call two edges in the complement of a subgraph H of a graph G "related" if they are both contained in a path in G that has no vertices of H in its interior. Then the bridges of H are the induced subgraphs on the equivalence classes of edges under this relation.

2. Informally, a bridge is a subgraph obtained from one of the "pieces" that result by deleting H from G by reattaching the endpoints to the edges that attach to H. See Example 1.

3. The time needed to test planarity by searching directly for subdivided copies of K_5 and $K_{3,3}$ is an exponential function of the number of vertices.

4. J. Hopcroft and R. Tarjan developed a planarity-testing algorithm that can be executed in time proportional to the number of vertices ("linear time").

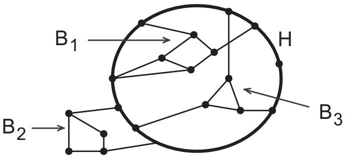
5. None of the linear-time planarity algorithms is easy to describe and implement. However, Algorithm 1 below is easily implemented, and its running time is satisfactory for reasonably large graphs.

6. Algorithm 1 can be implemented to run in time approximately proportional to the square of the number of vertices ("quadratic time").

```
Algorithm 1: Easy planarity-testing for graph G.
  input: a simple, connected graph G
  $G_0 :=$ an arbitrary cycle in $G$; draw $G_0$ in the plane; $j := 0$
  {Grow a sequence of nested subgraphs $G_0, G_1, \ldots$ until all of $G$ has been drawn
     in the plane; if this does not happen, then $G$ is nonplanar}
  while $G_j \neq G$ {This possible exit implies $G$ is planar} and $\big(\forall B \in \text{bridges } (G_j)\big)$
     $\big(\forall v \in \text{attachments } (B)\big)\big(\exists \text{ region } R \text{ of } G_j \text{ in plane}\big)\ v \in \partial R$ {This possible
     exit implies $G$ is nonplanar} do
     {While-loop body says how to grow subgraph $G_{j+1}$}
     if $\big(\exists B \in \text{bridges } (G_j)\big)\big(\forall v \in \text{attachments } (B)\big)\big(\exists! \text{ region } R \text{ of } G_j\big)\ \big[v \in \partial R\big]$
     then {Case 1 — a forced move exists}
        select a path $P$ between two attachments of $B$
        obtain subgraph $G_{j+1}$ by drawing path $P$ in region $R$
     else {Case 2 — no forced move exists}
        select any bridge, and find two regions for its attachments
        select any path between two attachments of that bridge
        draw that path into either region to obtain $G_{j+1}$
     $j := j + 1$
```

Example:

1. The following figure shows a subgraph and its three bridges B_1B_2, B_3. The subgraph H is the dark cycle. Attachments of the bridges are the vertices along the dark cycle.



2. Suppose that the figure in Example 1 occurred in the execution of Algorithm 1. At the next iteration of the while-loop body, suppose that bridge B_2 is selected, and suppose that a path in B_2 is drawn outside the dark cycle. Then, on the following iteration of the while-loop body, bridge B_3 would be a forced choice, and a path from B_3 would have to be drawn inside the dark cycle. Eventually, bridge B_1 would have to be drawn outside the dark cycle, thereby yielding a planar drawing of the entire graph.

8.7.4 CROSSING NUMBER AND THICKNESS

Definitions:

The ***crossing number*** of graph G, denoted $\nu(G)$, is the minimum number of edge-crossings possible in a normalized drawing of G in the plane.

The ***thickness*** of graph G, denoted $\theta(G)$, is the minimum number of planar graphs whose union is G.

Facts:

1. $\nu(K_n) \le \frac{1}{4} \cdot \lfloor \frac{n}{2} \rfloor \cdot \lfloor \frac{n-1}{2} \rfloor \cdot \lfloor \frac{n-2}{2} \rfloor \cdot \lfloor \frac{n-3}{2} \rfloor$.

2. For all integers $n \le 12$, $\nu(K_n) = \frac{1}{4} \cdot \lfloor \frac{n}{2} \rfloor \cdot \lfloor \frac{n-1}{2} \rfloor \cdot \lfloor \frac{n-2}{2} \rfloor \cdot \lfloor \frac{n-3}{2} \rfloor$.

3. It is conjectured that equality in Fact 2 holds for all positive integers.

4. $\nu(K_{m,n}) \le \lfloor \frac{m}{2} \rfloor \cdot \lfloor \frac{m-1}{2} \rfloor \cdot \lfloor \frac{n}{2} \rfloor \cdot \lfloor \frac{n-1}{2} \rfloor$.

5. For all integers m and n such that $\min(m,n) \le 6$, $\nu(K_{m,n}) = \lfloor \frac{m}{2} \rfloor \cdot \lfloor \frac{m-1}{2} \rfloor \cdot \lfloor \frac{n}{2} \rfloor \cdot \lfloor \frac{n-1}{2} \rfloor$.

6. *Zarankiewicz's conjecture*: The equation of Fact 5 holds for all positive integers m and n.

7. $\theta(K_n) = \lfloor \frac{n+7}{6} \rfloor$ except that $\theta(K_9) = \theta(K_{10}) = 3$.

8. $\theta(Q_n) = \lceil \frac{n+1}{4} \rceil$.

9. $\theta(G) \ge \left\lfloor \frac{|E|}{3|V|-6} \right\rfloor$ for all simple graphs.

Examples:

1. Fact 1 implies that $\nu(K_6) \le 3$. Thus, it is possible to draw K_6 with at most three crossings.

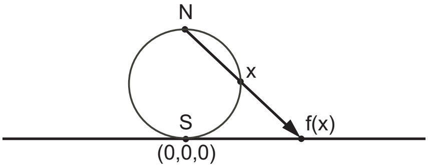
2. *Computer engineering*: Facts 7 and 8 yield lower bounds for the minimum number of layers needed for a multi-layer layout of an electronic interconnection network whose architecture is a complete graph or a hypercube graph, respectively.

8.7.5 STEREOGRAPHIC PROJECTION

Definitions:

A continuous one-to-one function from one subset of Euclidean space onto another is a ***topological equivalence*** if its inverse is continuous. (Informally, this means that either subset could be reshaped into the other without tearing, but only by compressing, stretching, and twisting.)

The ***stereographic projection*** adds a single point to a plane and thereby closes the "hole at infinity" and converts it into a sphere, as follows. Start with a sphere in 3-space, tangent at its south pole S to the plane $z = 0$ at the origin $(0, 0, 0)$, as shown in the following figure; and through each point x of the sphere draw a ray from the north pole N, extending to the point $f(x)$ at which it meets the plane.



Facts:

1. The correspondence $x \to f(x)$ from the sphere minus its north pole onto the plane is a topological equivalence. In other words, the sphere minus a point could be stretched apart at the missing point and flattened out so that it covers the plane.

2. Any planar imbedding can be transformed into an imbedding in the sphere, which is a closed surface, by using the inverse of stereographic projection and closing up the pinhole. This eliminates the inelegant nuisance of having one "special" region with a hole.

8.7.6 GEOMETRIC DRAWINGS

Geometric drawing of graphs is a topic in computational geometry. Unlike ordinarily planarity and topological graph theory, its concerns include the exact coordinates in the plane of the images of the vertices and the edges.

Definitions:

A ***straight-line drawing*** of a graph is a drawing in which each edge is represented by a single straight line segment.

An ***orthogonal drawing*** of a graph is a drawing in which each edge is represented by a chain of horizontal and vertical line segments.

A ***polyline drawing*** of a graph is a drawing in which each edge is represented by a polygonal path, that is, by a chain of line segments with arbitrary slope.

A ***bend*** in a polyline drawing is a junction point of two line segments belonging to the same edge.

A ***grid drawing*** of a graph is a polyline drawing in which vertices, crossings, and bends have integer coordinates.

The ***area of a graph drawing*** is the area of the convex hull of the drawing.

A ***distance-ranked partition*** of a graph G with respect to a nonempty vertex subset S has cells C_j for $j = 0, 1, \ldots$. Vertex v is in cell C_j if and only if its shortest path to every vertex of S has length j.

A ***distance-ranked drawing*** of a graph G with respect to a nonempty vertex subset S has the cells of its distance-ranked partition organized into columns from left to right according to ascending distance from S.

Facts:

1. Straight-line and orthogonal drawings are special cases of polyline drawings.

2. Polyline drawings can approximate drawings with curved edges.

3. Computer systems that support general polyline drawings are more complicated than systems that support only straight-line drawings.

4. Many graph drawing problems involve a trade-off between competing objectives, such as the desire to minimize both the area and the number of edge-crossings.

5. The area required for a planar polyline grid drawing of an n-vertex planar graph is $O(n^2)$.

6. The area required for a planar orthogonal grid drawing of an n-vertex planar graph is $O(n^2)$.

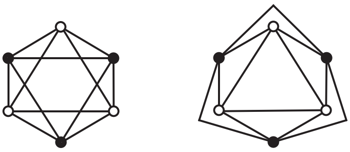
7. The area required for a planar straight line grid drawing of an n-vertex planar graph is $O(n^2)$.

8. Every planar graph of maximum degree 4 has an orthogonal planar drawing whose total number of bends is at most $2n + 2$.

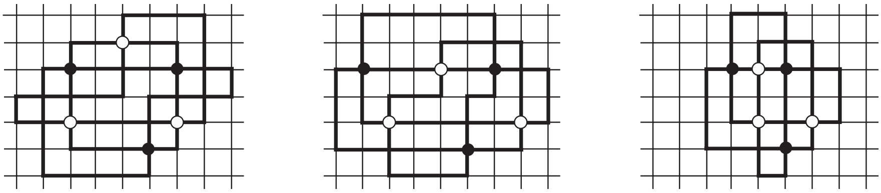
9. Every planar graph of maximum degree 4 has an orthogonal planar drawing such that the maximum number of bends in an edge is at most 2.

Examples:

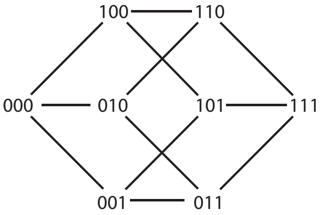
1. The following figure shows a nonplanar straight line drawing of the octahedron $K_{2,2,2}$ and a planar polyline drawing of that same graph.



2. The following figure shows two orthogonal grid drawings of the octahedron $K_{2,2,2}$. Whereas the lefthand drawing has two edges with three bends, the maximum number of bends in any edge of the middle drawing is two. The righthand drawing has the smallest total number of bends and the smallest area of the three drawings.



3. The following figure shows a distance-ranked drawing of the cube graph Q_3 with respect to the vertex 000.



8.8 TOPOLOGICAL GRAPH THEORY

Topological graph theory mainly involves placing graphs on closed surfaces. Special emphasis is given to placements that are minimum with respect to some kind of cost or that are highly symmetric. Minimization helps to control the cost of manufacturing networks, and symmetry facilitates the task of routing information through a network.

8.8.1 CLOSED SURFACES

Holes in a surface can be closed off by operations like stereographic projection (see §8.7.5). This enables topological graph theory to focus on drawings in closed surfaces.

Definitions:

Adding a handle to a surface is accomplished in two steps (illustrated in Example 1): (a) punch two disk-like holes into the surface; and (b) reclose the surface by installing a tube that runs from one hole to the other.

An ***orientable surface*** is defined recursively to be either the sphere S_0, or a surface that is obtained from an orientable surface by adding a handle. (See Example 2 for the construction.)

The ***genus of an orientable surface*** is the number of handles one must add to the sphere to obtain it. Thus, the surface obtained by adding g handles to S_0 has genus g. It is denoted S_g.

The ***torus*** is the surface S_1 of genus 1.

A ***Möbius band*** is the surface obtained by pasting the left side of a rectangular sheet to the right with a half-twist. A paper ring with a half-twist is a commonplace model of the Möbius band. (See Example 3.)

Adding a crosscap to a surface is accomplished by the following two steps: (a) punch one disk-like hole into the surface; and (b) reclose the hole by matching its boundary to the boundary of a Möbius band.

The ***nonorientable surface*** N_k is obtained by adding k crosscaps to the sphere. The sphere is sometimes regarded as the "surface with crosscap number 0" and denoted N_0, even though it is orientable. (See Example 4.)

The subscript k is called the ***crosscap number*** of the surface N_k.

The surfaces N_1 and N_2 are called the ***projective plane*** and the ***Klein bottle***, respectively.

Facts:

1. *Classification of closed surfaces*: Every closed surface is equivalent to exactly one of the surfaces S_g $(g \geq 0)$ or N_k $(k \geq 1)$.

2. Adding a handle to the nonorientable surface N_k is equivalent to adding two crosscaps. That is, the resulting surface is N_{k+2}.

3. If a loop is drawn around each handle of S_g and if these g loops are then cut open, the result is a (non-closed) surface that can be stretched and flattened out into a subset of the plane.

4. The subscript g equals the maximum number of closed curves on S_g that can be cut open without disconnecting that surface.

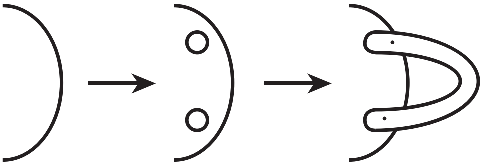
5. The subscript k equals the maximum number of closed curves on N_k that can be cut open without disconnecting that surface.

6. No closed nonorientable surface can be imbedded in $\mathcal{R}^3$.

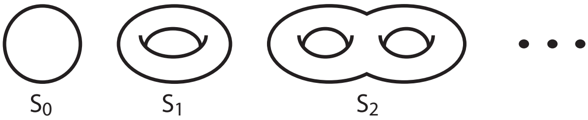
7. *Network layouts*: The surfaces actually used for computer interconnection network layouts and other practical purposes rarely have graceful curved shapes, because among other reasons, that would obstruct miniaturization and ease of manufacture. Moreover, such surfaces usually have holes. However, the classification theorem and the closing of holes reduce the topology of the layout problems to placing graphs on closed surfaces.

Examples:

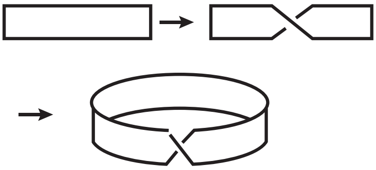
1. Adding a handle is achieved by punching two holes and connecting them with a tube, as illustrated.



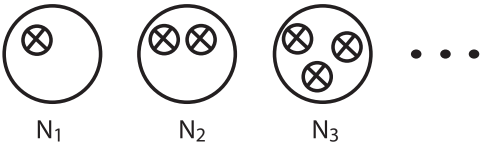
2. To construct the sequence of all orientable surfaces from the sphere S_0, each successive handle is added at the right of the previous surface.



3. The Möbius band is constructed by giving a half-twist to a rectangular strip and then pasting the ends together.



4. To construct the sequence of all nonorientable surfaces from the projective plane N_1, each successive crosscap is added by cutting a hole in the previous surface and capping it with a Möbius band.



8.8.2 DRAWING GRAPHS ON SURFACES

Definitions:

A ***flat-polygon representation of a surface*** S is a drawing of a flat polygon with markings to match the sides into pairs such that when the sides are pasted together as the markings indicate, the resulting surface S is obtained. (Certain special flat-polygon representations are called ***fundamental polygon representations***.) (See Example 1.)

An ***imbedding*** (or ***embedding***) of a graph is a drawing with no edge-crossings.

A ***face*** of an imbedding means a region plus its boundary. The set of all faces is denoted F.

The ***Euler characteristic of an imbedding*** of a graph $G = (V, E)$ is the number $|V| - |E| + |F|$.

A ***flat-polygon drawing of a graph*** on a surface has some graph edges drawn in two or more segments, so that one segment runs from one endpoint of an edge to a side of the flat polygon and another segment runs from the other endpoint to the corresponding position on the matched side of the flat polygon. Sometimes there are also some interior edge segments running between polygon sides. (Flat-polygon drawings are best used for small graphs.)

Imbedding modification (or "surgery") on a surface means adding handles and crosscaps to the surface and then drawing one or more edges that traverse the new handles and crosscaps.

The (Poincarè) ***duality construction*** (see Example 3) is as follows:

- insert into the interior of each (primal) face f a single dual vertex f^*;
- through each primal edge e draw a dual edge e^*; if edge e lies on the intersection of two primal faces f and f' (possibly $f = f'$), then the dual edge e^* joins the dual vertices f^* and f'^*;
- the ***dual graph*** is the graph $G^* = \big(\{ f^* \mid f \in F \},\ \{ e^* \mid e \in E \}\big)$;
- the ***dual imbedding*** is the resulting imbedding $G^* \to S$.

Facts:

1. Every closed surface has a flat-polygon representation. This makes it possible to draw a picture in the plane of any graph imbedding in any surface.

2. *Euler polyhedral equation for orientable surfaces*: Let $G = (V, E)$ be a connected graph, cellularly imbedded (see §8.8.3) into the surface S_g with face set F. Then

$$|V| - |E| + |F| = 2 - 2g = \chi(S_g).$$

3. *Euler polyhedral equation for nonorientable surfaces*: Let $G = (V, E)$ be a connected graph, cellularly imbedded into the surface N_k with face set F. Then

$$|V| - |E| + |F| = 2 - k = \chi(N_k).$$

4. *Edge-face inequality*: Let $G = (V, E)$ be a simple, connected graph imbedded in a surface with face set F. Then

$$2|E| \geq 3|F|.$$

5. *Edge-face inequality, strong version*: Let $G = (V, E)$ be a connected graph, but not a tree, imbedded in a surface with face set F. Then

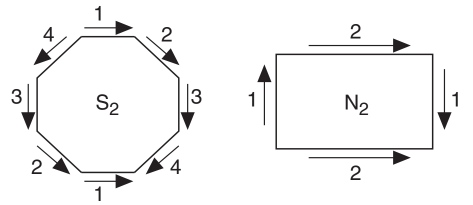
$$2|E| \geq \text{girth}(G) \cdot |F|.$$

6. The most frequently used method for constructing the imbeddings of a recursively constructable sequence of graphs is with voltage graphs. (See §8.10.3.)

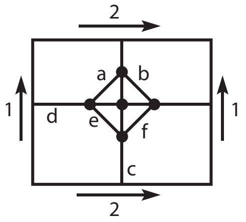
7. For each surface S_g, there is a finite list $\mathcal{L}_g$ of graphs analogous to the Kuratowski graphs K_5 and $K_{3,3}$. That is, a graph can be an imbedding in S_g if and only if it contains no subgraph homeomorphic to a graph in $\mathcal{L}_g$. (Robertson and Seymour, 1990)

Examples:

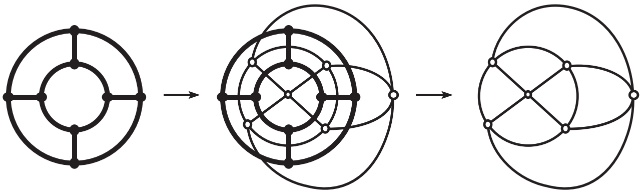
1. Flat-polygon representations of the double-torus and the Klein bottle are illustrated in the following diagrams.



2. In the imbedding $K_5 \to S_1$ illustrated below, edges c and d cross through flat-polygon sides 2 and 1, respectively. The "outer region" is actually 8-sided, with boundary circuit $\langle a, d, b, c, f, d, e, c \rangle$. Two pairs of sides of this region are pasted together. The appearance of this single region as four subregions at the corners of the flat polygon is a side-effect of the particular representation and not a true feature of the imbedding.



3. The Poincare duality construction is illustrated in the following diagram.



8.8.3 COMBINATORIAL REPRESENTATION OF GRAPH IMBEDDINGS

Definitions:

The ***rotation*** (***in*** "***edge-format***") at v is obtained from a flat-polygon drawing of a graph by the following sequence of steps: (a) label one end of each edge $+$ and the other end $-$, or put an arrow on each edge so that the head faces toward the $+$ end; and (b) at each vertex, traverse a small circle centered at that vertex, and record the cyclically ordered list of edge-ends encountered; this list is the rotation.

The ***vertex-format*** of a rotation is obtained by replacing each edge-end in the edge-format by the vertex at the other end of that edge. The vertex format is used only for simple graphs.

A ***rotation system*** is a complete list of rotations, that is, one for every vertex. If the surface is orientable, it is assumed that the traversals of the small circles around the vertices are in a consistent direction, that is, all clockwise or else all counterclockwise.

An imbedding is ***cellular*** (or a "2-cell imbedding") if every region is planar and has connected boundary.

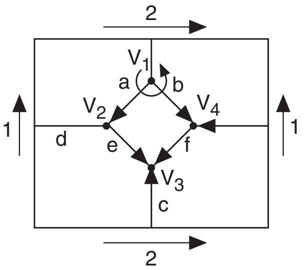
Facts:

1. Two cellular imbeddings of a graph are equivalent if and only if they have the same rotation system.

2. If a cellular graph imbedding is represented as a rotation system, then the regions can be reconstructed algorithmically.

Example:

1. An imbedding $K_4 \to S_1$ and both formats of its rotation system are shown next.



edge - format		vertex - format	
$V_{1.}$	a - b - c -	$V_{1.}$	V_2 V_4 V_3
$V_{2.}$	a + d - e -	$V_{2.}$	V_1 V_4 V_3
$V_{3.}$	c + f + e +	$V_{3.}$	V_1 V_4 V_2
$V_{4.}$	b + f - d +	$V_{4.}$	V_1 V_3 V_2

8.8.4 GENUS AND CROSSCAP NUMBER

Definitions:

The ***minimum genus*** (often, simply ***genus***) $\gamma_{\min}(G)$ of a connected graph G is the minimum integer g such that there is an imbedding of G into the surface S_g.

The ***maximum genus*** $\gamma_{\max}(G)$ of a connected graph G is the maximum integer g such that there is a cellular imbedding of G into the surface S_g.

The ***minimum crosscap number*** (often, simply ***crosscap number***) $\overline{\gamma}_{\min}(G)$ is the minimum integer k such that there is an imbedding of G into N_k. Thus, a planar graph has minimum crosscap number zero.

The ***maximum crosscap number*** $\overline{\gamma}_{\max}(G)$ is the maximum integer k such that there is a cellular imbedding of G into N_k. Thus, a planar graph has maximum crosscap number zero.

Facts:

1. The genus of any planar graph is 0.

2. $\gamma_{\min}(G) \geq \frac{|E| - 3|V| + 6}{6}$ if G is simple.

3. $\gamma_{\min}(G) \geq \frac{|E| - 2|V| + 4}{4}$ if G is simple and bipartite.

4. $\gamma_{\min}(K_n) = \left\lceil \frac{(n-3)(n-4)}{12} \right\rceil$. (Ringel and Youngs, 1968)

5. $\gamma_{\min}(K_{m,n}) = \left\lceil \frac{(m-2)(n-2)}{4} \right\rceil$. (Ringel, 1965)

6. $\gamma_{\min}(Q_n) = \left\lceil \frac{(m-2)(n-2)}{4} \right\rceil$. (Ringel, 1955)

7. $\overline{\gamma}_{\min}(G) \geq \left\lceil \frac{|E| - 3|V| + 6}{3} \right\rceil$ for every simple graph G.

8. $\overline{\gamma}_{\min}(G) \geq \left\lceil \frac{|E| - 2|V| + 4}{2} \right\rceil$ for every simple bipartite graph G.

9. $\overline{\gamma}_{\min}(K_n) = \left\lceil \frac{(n-3)(n-4)}{6} \right\rceil$, except that $\overline{\gamma}_{\min}(K_7) = 3$. (Ringel, 1959)

10. Many genus and crosscap number formulas can be derived by using *voltage graphs* or *current graphs* (see §8.10.4). [GrTu12]

11. For any genus g such that $\gamma_{\min}(G) \leq g \leq \gamma_{\max}(G)$, there is at least one imbedding of the graph G in the surface S_g.

12. For any crosscap number k such that $\overline{\gamma}_{\min}(G) \leq k \leq \overline{\gamma}_{\max}(G)$, there is at least one imbedding of the graph G in the surface N_k.

13. The problem of calculating the minimum genus of a graph is NP-hard. (Thomassen, 1989)

14. The problem of calculating the maximum genus of a graph is solvable in polynomial time. (Furst, Gross, and McGeoch, 1988)

8.9 ENUMERATING GRAPHS

It is often important to know how many graphs there are with some desired property; for example, this is used in computer science to analyze the requirements of algorithms, and in chemistry to catalogue chemical molecules with various shapes. Many of the techniques for counting graphs are based on the master theorem in the historic 1937 work of George Pólya [PóRe87]. Frank Harary and others exploited this master theorem in counting graphs, multigraphs, digraphs, and similar graphical structures. An exhaustive survey of results in graph enumeration can be found in [HaPa73]. Alternatively, if you know the first few terms of a graph-counting sequence, you can likely find more terms, references, and further information in the *On-Line Encyclopedia of Integer Sequences* [OEIS].

8.9.1 COUNTING LABELED GRAPHS AND MULTIGRAPHS

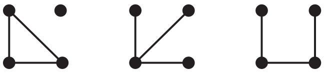
When counting graphs, it is important to distinguish between the enumeration of labeled graphs and that of unlabeled graphs. Labeled graphs are relatively easy to count, usually requiring only factorials, exponentials, and binomial coefficients.

Definitions:

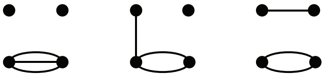
A ***labeled graph*** or ***labeled multigraph*** is a graph or multigraph with standard labels (commonly $v_1, v_2, \ldots, v_n$) assigned to the vertices. Two labeled graphs or multigraphs with the same set of labels are considered the same only if there is an isomorphism from one to the other that preserves the labels.

Examples:

1. The following figure shows the three isomorphically distinct graphs with 4 vertices and 3 edges. There are 4 essentially different ways to label each of the first two and 12 ways to label the third. Thus there are 20 different labeled graphs with 4 vertices and 3 edges.



2. The next figure shows the three isomorphically distinct loopless multigraphs that together with the graphs in the previous figure form the six different multigraphs with 4 vertices and 3 edges. There are 6 essentially different ways to label the first and third graphs in this figure and 24 ways to label the middle graph. Thus the multigraphs in these two figures represent the total of 56 labeled loopless multigraphs with 4 vertices and 3 edges.



Facts:

1. The number of labeled graphs with n vertices and m edges is the binomial coefficient $\binom{\binom{n}{2}}{m}$. These numbers form sequence A084546 in [OEIS]. See Table 1.

Table 1: Labeled graphs with n vertices and m edges.

$m\backslash n$	1	2	3	4	5	6	7	8
0	1	1	1	1	1	1	1	1
1		1	3	6	10	15	21	28
2			3	15	45	105	210	378
3			1	20	120	455	1,330	3,276
4				15	210	1,365	5,985	20,475
5				6	252	3,003	20,349	98,280
6				1	210	5,005	54,264	376,740
7					120	6,435	116,280	1,184,040
8					45	6,435	203,490	3,108,105
9					10	5,005	293,930	6,906,900
10					1	3,003	352,716	13,123,110
11						1,365	352,716	21,474,180
12						455	293,930	30,421,755
13						105	203,490	37,442,160
14						15	116,280	40,116,600
total	1	2	8	64	1,024	32,768	2,097,152	268,435,456

2. For $m > \binom{n}{2}/2$, the number of labeled graphs with n vertices and m edges is the same as the number of labeled graphs with n vertices and $\binom{n}{2} - m$ edges.

3. The total number of labeled graphs with n vertices is $2^{\binom{n}{2}}$. This is sequence A006125 in [OEIS]. See Table 1.

4. The number C_n of connected labeled graphs with n vertices can be determined from the following recurrence system.

$$C_1 = 1, \quad \text{and} \quad C_n = 2^{\binom{n}{2}} - \frac{1}{n}\sum_{k=1}^{n-1} k\binom{n}{k} 2^{\binom{n-k}{2}} C_k \quad \text{for } n > 1.$$

This is sequence A001187 in [OEIS]. See Table 2.

Table 2: Connected labeled graphs with n vertices.

n	1	2	3	4	5	6	7	8
C_n	1	1	4	38	728	26,704	1,866,256	251,548,592

5. Asymptotically, most labeled graphs are connected. Thus the sequence C_n satisfies

$$C_n \sim 2^{\binom{n}{2}}.$$

6. The number of labeled loopless multigraphs with n vertices and m edges is the binomial coefficient $\binom{m+\binom{n}{2}-1}{m}$. When $n = 1$, this expression should be interpreted as 1 when $m = 0$ and 0 otherwise. See Table 3. These numbers form the sequence A098568 in [OEIS].

Table 3: Labeled loopless multigraphs with n vertices and m edges.

$m\backslash n$	1	2	3	4	5	6	7	8
0	1	1	1	1	1	1	1	1
1		1	3	6	10	15	21	28
2		1	6	21	55	120	231	406
3		1	10	56	220	680	1,771	4,060
4		1	15	126	715	3,060	10,626	31,465
5		1	21	252	2,002	11,628	53,130	201,376
6		1	28	462	5,005	38,760	230,230	1,107,568

8.9.2 COUNTING UNLABELED GRAPHS AND MULTIGRAPHS

Unlike the enumeration of labeled graphs, the enumeration of unlabeled graphs requires rather sophisticated counting techniques, often utilizing permutation group theory and generating functions.

Definitions:

The ***symmetric group*** S_n is the group of all $n!$ permutations γ acting on the set $X_n = \{1, 2, \ldots, n\}$.

The ***order*** of a permutation group is the number of permutations it contains. The ***degree*** of a permutation group is the number of objects being permuted. The symmetric group S_n has order $n!$ and degree n.

The ***cycle index*** $Z(G)$ of a permutation group G of order m and degree d is a polynomial in variables $a_1, a_2, \ldots, a_d$ given by the formula

$$Z(G) = \frac{1}{m} \sum_{\gamma \in G} \prod_{k=1}^{d} a_k^{j_k(\gamma)},$$

where $j_k(\gamma)$ is the number of cycles of length k in the permutation γ. For example, for $G = S_3 = \{(1)(2)(3),\ (123),\ (132),\ (1)(23),\ (2)(13),\ (3)(12)\}$, the symmetric group of order 6 and degree 3, the cycle index is $Z(G_3) = \frac{1}{6}\left(a_1^3 + 2a_3 + 3a_1a_2\right)$.

The ***pair permutation*** $\gamma^{(2)}$ induced by the permutation γ acting on the set X_n is the permutation acting on unordered pairs of distinct elements of X_n defined by the rule

$$\gamma^{(2)}\left(\{x_1, x_2\}\right) = \{\gamma(x_1), \gamma(x_2)\}.$$

The ***symmetric pair group*** $S_n^{(2)}$ induced by the symmetric group S_n is the permutation group $\left\{\gamma^{(2)} \mid \gamma \in S_n\right\}$. This group has order $n!$ and degree $n(n-1)/2$.

Facts:

1. The cycle index $Z(S_n^{(2)})$ of the symmetric pair group, used in counting graphs with n vertices, is

$$Z(S_n^{(2)}) = \frac{1}{n!} \sum_{(j)} \frac{n!}{\prod_k k^{j_k} j_k!} \prod_k a_k^{k\binom{j_k}{2}} (a_k a_{2k}^{k-1})^{j_{2k}} a_{2k+1}^{kj_{2k+1}} \prod_{r<s} a_{\mathrm{lcm}(r,s)}^{\gcd(r,s) j_r j_s},$$

where $\operatorname{lcm}(r, s)$ and $\gcd(r, s)$ are the least common multiple and greatest common divisor of r and s, respectively. The sum is taken over all partitions $(j) = j_1, j_2, \ldots, j_n$ of the integer n as an unordered sum of parts, where j_k is the number of parts of size k. For example, in the partition of 7 as $2 + 2 + 3$ we have $j_2 = 2$, $j_3 = 1$, and $j_1 = j_4 = j_5 = j_6 = j_7 = 0$. Explicit formulas for $Z(S_n^{(2)})$ for small values of n are

$$\begin{aligned}
Z\big(S_1^{(2)}\big) &= 1\\
Z\big(S_2^{(2)}\big) &= a_1\\
Z\big(S_3^{(2)}\big) &= \frac{1}{3!}\big(a_1^3 + 3a_1a_2 + 2a_3\big)\\
Z\big(S_4^{(2)}\big) &= \frac{1}{4!}\big(a_1^6 + 9a_1^2a_2^2 + 8a_3^2 + 6a_2a_4\big)\\
Z\big(S_5^{(2)}\big) &= \frac{1}{5!}\big(a_1^{10} + 10a_1^4a_2^3 + 20a_1a_3^3 + 15a_1^2a_2^4 + 30a_2a_4^2 + 20a_1a_3a_6 + 24a_5^2\big)\\
Z\big(S_6^{(2)}\big) &= \frac{1}{6!}\big(a_1^{15} + 15a_1^7a_2^4 + 40a_1^3a_3^4 + 60a_1^3a_2^6 + 180a_1a_2a_4^3 + 120a_1a_2a_3^2a_6\\
&\qquad + 144a_5^3 + 40a_3^5 + 120a_3a_6^2\big)
\end{aligned}$$

2. Let $G_{n,m}$ denote the number of graphs with n vertices and m edges, and let $g_n(x)$ be the generating function for n-vertex graphs, so that

$$g_n(x) = \sum_{m=0}^{\binom{n}{2}} G_{n,m}x^m.$$

Pólya's enumeration theorem states that this generating function $g_n(x)$ can be obtained from the cycle index $Z(S_n^{(2)})$ by replacing each variable a_i with $1 + x^i$. See Table 4. These numbers form sequence A008406 in [OEIS].

3. For $m > \binom{n}{2}/2$, the number of graphs with n vertices and m edges is the same as the number of graphs with n vertices and $\binom{n}{2} - m$ edges.

4. The total number G_n of graphs with n vertices is obtained from the cycle index $Z(S_n^{(2)})$ by replacing each variable a_i with the number 2. See Table 4. This is sequence A000088 in [OEIS].

5. Asymptotically, the sequence G_n satisfies $G_n \sim 2^{\binom{n}{2}}/n!$.

Table 4: Graphs with n vertices and m edges.

$m \backslash n$	1	2	3	4	5	6	7	8
0	1	1	1	1	1	1	1	1
1		1	1	1	1	1	1	1
2			1	2	2	2	2	2
3			1	3	4	5	5	5
4				2	6	9	10	11
5				1	6	15	21	24
6				1	6	21	41	56
7					4	24	65	115

$m \backslash n$	1	2	3	4	5	6	7	8
8					2	24	97	221
9					1	21	131	402
10					1	15	148	663
11						9	148	980
12						5	131	1,312
13						2	97	1,557
14						1	65	1,646
Total	1	2	4	11	34	156	1,044	12,346

6. The enumeration of connected graphs requires an auxiliary sequence A_n defined recursively by

$$A_1 = 1, \quad \text{and} \quad A_n = nG_n - \sum_{k=1}^{n-1} A_k \cdot G_{n-k} \quad \text{for } n > 1.$$

This sequence 1, 3 ,7, 27, 106, 681, 5972, 88963, ... is sequence A003083 in [OEIS]. The number K_n of connected graphs with n vertices can then be computed as

$$K_n = \frac{1}{n} \sum_{d|n} \mu(d) A_{n/d},$$

where the sum is over all divisors of n and μ is the Möbius function defined by

$$\mu(n) = \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{if } m^2|n \text{ for some } m > 1 \\ (-1)^k & \text{if } n \text{ is the product of } k \text{ distinct primes.} \end{cases}$$

See Table 5. The sequence K_n is sequence A001349 in [OEIS].

Table 5: Connected graphs with n vertices.

n	1	2	3	4	5	6	7	8
K_n	1	1	2	6	21	112	853	11,117

7. Asymptotically, most graphs are connected. Thus the sequence K_n satisfies $K_n \sim 2^{\binom{n}{2}}/n!$.

8. Let $M_{n,k}$ denote the number of loopless multigraphs with n vertices and k edges, and let $m_n(x)$ be the generating function for n-vertex loopless multigraphs, so that

$$m_n(x) = \sum_{m=0}^{\binom{n}{2}} M_{n,k} x^k.$$

Pólya's enumeration theorem states that this generating function $m_n(x)$ can be obtained from the cycle index $Z(S_n^{(2)})$ by replacing each variable a_i with the infinite series $1 + x^i + x^{2i} + x^{3i} + \cdots$. See Table 6. These numbers form sequence A192517 in [OEIS]. (Also, column $n = 3$ is sequence A001399, column $n = 4$ is sequence A003082, column $n = 5$ is sequence A014395, and column $n = 6$ is sequence A014396.)

Table 6: Loopless multigraphs with n vertices and m edges.

$m \backslash n$	1	2	3	4	5	6
0	1	1	1	1	1	1
1		1	1	1	1	1
2		1	2	3	3	3
3		1	3	6	7	8
4		1	4	11	17	21
5		1	5	18	35	52
6		1	7	32	76	132
7		1	8	48	149	313
8		1	10	75	291	741
9		1	12	111	539	1,684
10		1	14	160	974	3,711

8.9.3 COUNTING LABELED DIGRAPHS AND TOURNAMENTS

Definitions:

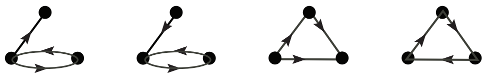
A ***labeled digraph*** is a digraph with distinct labels, typically $v_1, v_2, \ldots, v_n$, assigned to its vertices. Two labeled digraphs with the same set of labels are considered the same only if there is an isomorphism from one to the other that preserves the labels.

A ***tournament*** (or ***round-robin tournament***) is a digraph in which, for each pair u, v of distinct vertices, either there exists an arc from u to v or an arc from v to u but not both.

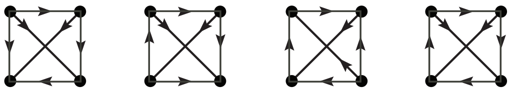
A digraph is ***strong*** (or ***strongly connected***) if for each pair u, v of vertices, there exist directed paths from u to v and from v to u. A strong tournament is also called an ***irreducible*** tournament.

Examples:

1. The following figure shows the four isomorphically distinct digraphs with 3 vertices and 3 arcs. The last two are tournaments. There are 6 essentially different ways to label each of the first three digraphs and 2 ways to label the fourth. Thus there are 20 different labeled digraphs with 3 vertices and 3 arcs. Only the last digraph is strong—an irreducible tournament.



2. The next figure shows the four isomorphically distinct tournaments with 4 vertices. There are 24 essentially different ways to label the first and last tournaments, and 8 ways to label each of the middle two. Thus there are 64 different labeled tournaments with 4 vertices. Only the last tournament is strong.



Facts:

1. The number of labeled digraphs with n vertices and m arcs is the binomial coefficient $\binom{n(n-1)}{m}$. See Table 7. These numbers form sequence A123554 in [OEIS].

Table 7: Labeled digraphs with n vertices and m arcs.

$m \backslash n$	1	2	3	4	5
0	1	1	1	1	1
1		2	6	12	20
2		1	15	66	190
3			20	220	1,140
4			15	495	4,845
5			6	792	15,504
6			1	924	38,760
7				792	77,520
8				495	125,970
9				220	167,960
10				66	184,756
Total	1	4	64	4,096	1,048,576

2. For $m > n(n-1)/2$, the number of labeled digraphs with n vertices and m arcs is the same as the number of labeled digraphs with n vertices and $n(n-1) - m$ arcs.

3. The total number of labeled digraphs with n vertices is $2^{n(n-1)}$. See Table 7. This is sequence A053763 in [OEIS].

4. The number of labeled tournaments with n vertices is $2^{\binom{n}{2}}$, the same as the number of labeled graphs with n vertices. See Table 8. This is sequence A006125 in [OEIS].

5. The number $\widehat{S_n}$ of strong labeled tournaments with n vertices can be computed from the recursive formula

$$\widehat{S_1} = 1, \quad \text{and} \quad \widehat{S_n} = 2^{\binom{n}{2}} - \sum_{k=1}^{n-1} \binom{n}{k} 2^{\binom{n-k}{2}} \widehat{S_k} \quad \text{for } n > 1.$$

See Table 8. This is sequence A054946 in [OEIS].

Table 8: Labeled tournaments and strong tournaments with n vertices.

n	Labeled Tournaments	Strong Labeled Tournaments
1	1	1
2	2	0
3	8	2
4	64	24
5	1,024	544
6	32,768	22,320
7	2,097,152	1,677,488
8	268,435,456	236,522,496

6. Asymptotically, most labeled tournaments are strong. Thus the sequence $\widehat{S_n}$ counting strong labeled tournaments satisfies $\widehat{S_n} \sim 2^{\binom{n}{2}}$.

8.9.4 COUNTING UNLABELED DIGRAPHS AND TOURNAMENTS

As with unlabeled graphs, the enumeration of unlabeled digraphs and tournaments requires rather sophisticated counting techniques, often utilizing permutation group theory and generating functions. (See §8.9.2.)

Definitions:

The ***ordered pair permutation*** $\gamma^{[2]}$ induced by the permutation γ acting on the set $X_n = \{1, 2, \dots , n\}$ is the permutation acting on ordered pairs of distinct elements of X_n defined by the rule

$$\gamma^{[2]}\left((x_1, x_2)\right) = \left(\gamma(x_1), \gamma(x_2)\right).$$

The ***reduced ordered pair group*** $S_n^{[2]}$ induced by the symmetric group S_n is the permutation group $\left\{\gamma^{[2]} \mid \gamma \in S_n\right\}$. This group has order $n!$ and degree $n(n-1)$.

Facts:

1. The cycle index $Z(S_n^{[2]})$ of the reduced ordered pair group, used in counting digraphs with n vertices, is

$$Z(S_n^{[2]}) = \frac{1}{n!}\sum_{(j)} \frac{n!}{\prod_k k^{j_k} j_k!} \prod_k a_k^{(k-1)j_k + 2k\binom{j_k}{2}} \prod_{r<s} a_{\mathrm{lcm}(r,s)}^{2\gcd(r,s) j_r j_s},$$

where lcm(r, s) and gcd(r, s) are the least common multiple and greatest common divisor of r and s, respectively. The sum is taken over all partitions $(j) = j_1, j_2, \dots, j_n$ of the integer n as an unordered sum of parts, where j_k is the number of parts of size k. (See §2.5 for a discussion of partitions.) Explicit formulas for $Z(S_n^{[2]})$ for small values of n are

$$Z\big(S_1^{[2]}\big) = 1$$

$$Z\big(S_2^{[2]}\big) = \frac{1}{2!}\big(a_1^2 + a_2\big)$$

$$Z\big(S_3^{[2]}\big) = \frac{1}{3!}\big(a_1^6 + 3a_2^3 + 2a_3^2\big)$$

$$Z\big(S_4^{[2]}\big) = \frac{1}{4!}\big(a_1^{12} + 6a_1^2a_2^5 + 8a_3^4 + 3a_2^6 + 6a_4^3\big)$$

$$Z\big(S_5^{[2]}\big) = \frac{1}{5!}\big(a_1^{20} + 10a_1^6a_2^7 + 20a_1^2a_3^6 + 15a_2^{10} + 30a_4^5 + 20a_2a_3^2a_6^2 + 24a_5^4\big)$$

$$\begin{aligned} Z\big(S_6^{[2]}\big) = \frac{1}{6!}\big(&a_1^{30} + 15a_1^{12}a_2^9 + 40a_1^6a_3^8 + 45a_1^2a_2^{14} + 90a_1^2a_4^7 + 120a_2^3a_3^4a_6^2 \\ &+ 144a_5^6 + 15a_2^{15} + 90a_2a_4^7 + 40a_3^{10} + 120a_6^5\big). \end{aligned}$$

2. Let $D_{n,m}$ denote the number of digraphs with n vertices and m arcs, and let $d_n(x)$ be the generating function for n-vertex digraphs, so that

$$d_n(x) = \sum_{m=0}^{n(n-1)} D_{n,m} x^m.$$

Pölya's enumeration theorem states that this generating function $d_n(x)$ can be obtained from the cycle index $Z(S_n^{[2]})$ by replacing each variable a_i with $1+x^i$. See Table 9. These numbers form sequence A052283 in [OEIS].

Table 9: Digraphs with n vertices and m arcs.

$m\backslash n$	1	2	3	4	5
0	1	1	1	1	1
1		1	1	1	1
2		1	4	5	5
3			4	13	16
4			4	27	61
5			1	38	154
6			1	48	379
7				38	707
8				27	1,155
9				13	1,490
10				5	1,670
Total	1	3	16	218	9,608

3. For $m > n(n-1)/2$, the number of digraphs with n vertices and m arcs is the same as the number of digraphs with n vertices and $n(n-1)-m$ arcs.

4. The total number D_n of digraphs with n vertices is obtained from the cycle index $Z(S_n^{[2]})$ by replacing each variable a_i with the number 2. See Table 9. This is sequence A000273 in [OEIS].

5. Asymptotically, the sequence D_n satisfies $D_n \sim 2^{n(n-1)}/n!$.

6. The number T_n of tournaments with n vertices is given by the formula

$$T_n = \frac{1}{n!}\sum_{(j)}{}^{'} \frac{n!}{\prod\limits_k k^{j_k} j_k!} 2^{D(j)},$$

where the sum is over all partitions (j) of n into odd size parts, and where

$$D(j) = \frac{1}{2}\left(\sum_{r=1}^{n}\sum_{s=1}^{n} \gcd(r,s) j_r j_s - \sum_{k=1}^{n} j_k\right).$$

See Table 10. This is sequence A000568 in [OEIS].

7. The number S_n of strong tournaments with n vertices can be determined by the recurrence relation

$$S_1 = 1, \quad \text{and} \quad S_n = T_n - \sum_{k=1}^{n-1} T_{n-k} S_k \quad \text{for } n > 1,$$

where T_n is the number of tournaments from Fact 6 above. See Table 10. Note that there are no strong tournaments with exactly two vertices. This is sequence A051337 in [OEIS].

8. The sequences T_n and S_n satisfy $T_n \sim S_n \sim 2^{\binom{n}{2}}/n!$.

Table 10: Tournaments and strong tournaments with n vertices.

n	Tournaments	Strong Tournaments
1	1	1
2	1	0
3	2	1
4	4	1
5	12	6
6	56	35
7	456	353
8	6,880	6,008
9	191,536	178,133
10	9,733,056	9,355,949
11	903,753,248	884,464,590
12	154,108,311,168	152,310,149,735

8.10 GRAPH FAMILIES

This section discusses some graph families and the theory behind them: perfect graphs, eigenvalues, algebraically-defined graphs, expander graphs, and product graphs.

8.10.1 PERFECT GRAPHS

The class of perfect graphs was introduced by Claude Berge in 1961. Around the same time Berge made two conjectures about this class of graphs that motivated a great deal of research in the field. Both conjectures have by now been solved, and are known as the Weak and Strong Perfect Graph Theorems. Below is a brief discussion of perfect graphs and of some recent developments on the topic. For more information see the appropriate section in [GrYeZh15].

Definitions:

An ***induced subgraph*** of G is a subgraph H such that every edge of G that joins two vertices of H is also an edge of H.

A graph G is called ***perfect*** if for every induced subgraph H of G, $\chi(H) = \omega(H)$ (where χ denotes the chromatic number and ω the clique number; see §8.6.3).

A ***hole*** in a graph is an induced subgraph that is isomorphic to the cycle C_k with $k \geq 4$, and k is the ***length*** of the hole. A hole is ***odd*** if k is odd, and ***even*** otherwise.

An ***antihole*** in a graph is an induced subgraph whose complement is isomorphic to C_k with $k \geq 4$, and k is the ***length*** of the antihole. An antihole is ***odd*** if k is odd, and ***even*** otherwise.

A graph is called ***Berge*** if it has no odd hole and no odd antihole.

A Berge graph G is called ***basic*** if: (a) G or its complement is bipartite; (b) G or its complement is the line graph of a bipartite graph; or (c) G is a double split graph.

An ***even pair*** is a pair of vertices $\{u, v\}$ such that every induced path from u to v has even length (in particular, v and v are nonadjacent). The operation of ***contracting even pair*** $\{u, v\}$ means replacing $\{u, v\}$ by a vertex w such that w is adjacent precisely to all vertices that were adjacent to at least one of u or v.

A graph G is called ***even contractile*** if one can repeatedly contract an even pair and end up with the complete graph on $\omega(G)$ vertices.

A ***prism*** is an induced subgraph consisting of two triangles $\{a_1, a_2, a_3\}$ and $\{b_1, b_2, b_3\}$ and three disjoint paths P_1, P_2, P_3, where P_i is from a_i to b_i, and for $1 \leq i < j \leq 3$ the only edges between $V(P_i)$ and $V(P_j)$ are a_ia_j and b_ib_j. A prism is ***odd*** if P_1, P_2, P_3 all have odd length, and ***even*** if P_1, P_2, P_3 all have even length.

Results:

1. An odd hole has $\omega = 2$ and $\chi = 3$; an odd antihole of length k has $\omega = (k-1)/2$ and $\chi = (k+1)/2$. Therefore a perfect graph cannot contain either.

2. *Weak Perfect Graph Theorem*: A graph is perfect if and only if its complement is perfect. [Lo72]

3. *Strong Perfect Graph Theorem*: A graph is perfect if and only if it has no odd hole and no odd antihole. [ChEtal06]

4. The strong theorem implies the weak.

5. There is a polynomial-time algorithm to test if an input graph is perfect.

6. If a graph is restricted to being perfect, then some algorithmic problems, such as calculating the size of the largest clique or finding an optimal coloring, that are NP-complete in general, can be solved in polynomial time.

7. If G is Berge and G' is formed by contracting an even pair, then G' is Berge and $\omega(G') = \omega(G)$.

8. If a prism is Berge, then either it is an odd prism or an even prism.

9. It is conjectured that if a Berge graph has no odd prism and no antihole of length at least six, then it is even contractile.

10. It is known that if a Berge graph has no prism and no antihole of length at least six, then it is even contractile. Also, if a Berge graph has no odd prism and no hole of length four, then it has an even pair.

8.10.2 SPECTRAL GRAPH THEORY

In this subsection we consider only undirected graphs.

Definitions:

The ***characteristic polynomial of a graph G*** is the characteristic polynomial $p(x)$ of its ***adjacency matrix*** A_G; that is, $p(x) = \det(xI - A_G)$.

An ***eigenvalue*** (or ***characteristic value***) ***of a matrix A*** is a number λ such that $Ax = \lambda x$, for some nonzero vector x; the vector x is an ***eigenvector*** (or ***characteristic vector***).

An ***eigenvector of a graph*** is an eigenvector of its adjacency matrix, and an ***eigenvalue of a graph*** an eigenvalue of its adjacency matrix.

The ***spectrum of a graph*** is the spectrum of its adjacency matrix; that is, the multiset of eigenvalues.

The ***Laplacian*** (or ***admittance matrix***) ***of a graph*** $\boldsymbol{G}$ is the matrix $D_G - A_G$, where D_G is the diagonal matrix with the degree sequence of G on the diagonal and A_G is the adjacency matrix.

A connected graph G is ***strongly regular with parameters*** $(\boldsymbol{n}, \boldsymbol{k}, \boldsymbol{r}, \boldsymbol{s})$ if

- $|V_G| = n$;
- G is k-regular, with $k > 0$;
- every pair of adjacent vertices is mutually adjacent to r other vertices;
- every pair of nonadjacent vertices is mutually adjacent to s other vertices.

The ***Hoffman polynomial of a graph*** is a polynomial $p(x)$ of minimum degree such that $p(A_G) = J$, where A_G is the adjacency matrix and J is the square matrix with every entry equal to 1.

A ***cospectral pair of graphs*** is a pair of nonisomorphic graphs that have the same spectrum.

Facts:

1. The eigenvalues of a graph are independent of the particular labeling of the vertices; thus, two isomorphic graphs have the same spectrum.

2. All the eigenvalues of a graph are real. This is a special case of the well-known linear algebra result that the eigenvalues of any Hermitian matrix are real.

3. From linear algebra, it follows that the characteristic polynomial of a graph G satisfies the equation $p(x) = \prod_{i=1}^{n}(x - \lambda_i)$, where $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of G.

4. If a graph is connected, then its largest eigenvalue has multiplicity 1. This eigenvalue has a corresponding eigenvector with all positive entries, which is the only such eigenvector.

5. If λ is the largest eigenvalue of a graph and μ is another eigenvalue, then $\lambda \geq |\mu|$; moreover, $-\lambda$ is an eigenvalue if and only if the graph is bipartite.

6. A graph is bipartite if and only if its spectrum is symmetric with respect to 0; that is, λ is an eigenvalue if and only if $-\lambda$ is also an eigenvalue.

7. The largest eigenvalue of a k-regular graph is k, and it has multiplicity equal to the number of connected components. The sum of the coordinates of an eigenvector corresponding to any other eigenvalue is 0.

8. The (i, j)th entry of the kth power A_G^k of the adjacency matrix of a graph G is the number of walks of length k starting at vertex v_i and terminating at v_j.

9. If $\lambda_1, \lambda_2, \ldots, \lambda_n$ are the eigenvalues of a graph G, then $\sum_{i=1}^{n} \lambda_i^2 = 2|E_G|$ where E_G is the edge-set of G. Also, $\sum_{i=1}^{n} \lambda_i^3 = 6T$ where T is the number of triangles in G.

10. If $p(x) = x^n + a_{n-1}x^{n-1} + a_{n-2}x^{n-2} + \cdots + a_1 x + a_0$ is the characteristic polynomial of a graph G, then $a_{n-1} = 0$, $-a_{n-2}$ is the number of edges, and $-a_{n-3}$ is twice the number of triangles.

11. The set of eigenvalues of the disjoint sum $G+H$ is the union of the sets of eigenvalues of G and H. The multiplicity of λ as an eigenvalue of $G+H$ is the sum of the multiplicity of λ as an eigenvalue of G and the multiplicity of λ as an eigenvalue of H.

12. The eigenvalues of the Cartesian product $G \,\square\, H$ are $\{\lambda_i+\lambda_j \mid \lambda_i$ an eigenvalue of G and λ_j an eigenvalue of $H\}$. The multiplicity of $\lambda_i + \lambda_j$ as an eigenvalue of $G \,\square\, H$ is the product of the multiplicity of λ_i as an eigenvalue of G and λ_j as an eigenvalue of H.

13. If G is a k-regular graph and $\overline{G}$ its complement, then $\lambda < k$ is an eigenvalue of G if and only if $-\lambda - 1$ is an eigenvalue of $\overline{G}$. In this case λ and $-\lambda - 1$ have the same multiplicities.

14. If λ is an eigenvalue of G with multiplicity m, then $-\lambda - 1$ is an eigenvalue of $\overline{G}$ with multiplicity $m-1$, m, or $m+1$.

15. If G has n vertices and $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ as eigenvalues, and H is an induced subgraph with $n-1$ vertices and eigenvalues $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_{n-1}$, then $\lambda_1 \geq \mu_1 \geq \lambda_2 \geq \mu_2 \geq \cdots \geq \mu_{n-1} \geq \lambda_n$. (See §6.5.5.)

16. The eigenvalues of a line graph $L(G)$ are greater than or equal to -2. Equality is attained unless every connected component of G is a tree or has exactly one circuit, that circuit being odd.

17. If G is a k-regular graph with $\lambda > -k$ as an eigenvalue, then $\lambda+k-2$ is an eigenvalue of $L(G)$.

18. A graph has a Hoffman polynomial if and only if it is regular and connected.

19. A regular connected graph has exactly three distinct eigenvalues if and only if it is strongly regular.

20. *Matrix-tree theorem*: If M_i is formed by deleting the ith row and column from the Laplacian of G, then $\det(M_i)$ is independent of the choice of i and is equal to the number of spanning trees of G.

Examples:

1. The edgeless graph on n vertices has one eigenvalue, namely 0 with multiplicity n.

2. The eigenvalues of the complete graph K_n are $n-1$ and -1 with respective multiplicities of 1 and $n-1$. For instance, the characteristic polynomial of K_4 is

$$\begin{vmatrix} x & -1 & -1 & -1 \\ -1 & x & -1 & -1 \\ -1 & -1 & x & -1 \\ -1 & -1 & -1 & x \end{vmatrix} = (x+1)^3\,(x-3)\,.$$

3. The eigenvalues of the complete bipartite graph $K_{m,n}$ are $\sqrt{mn}$, 0, and $-\sqrt{mn}$, with respective multiplicities of 1, $mn-2$, and 1.

4. The eigenvalues of the Petersen graph are 3, 1, and -2, with respective multiplicities 1, 5, and 4.

5. The eigenvalues of the n-path P_n are $\{2\cos\frac{k\pi}{n+1} \mid k = 1, 2, \ldots, n\}$, each with multiplicity 1.

6. The eigenvalues of the n-cycle C_n, are $\{2\cos\frac{2k\pi}{n} \mid k = 1, 2, \ldots, n\}$. The eigenvalue 2, and the eigenvalue -2 when n is even, have multiplicity 1; all other eigenvalues have multiplicity 2.

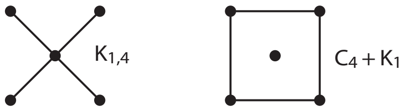
7. The eigenvalues of the hypercube Q_d are $d, d-2, d-4, \ldots, -d+2, -d$, with respective multiplicities $\binom{d}{0}, \binom{d}{1}, \binom{d}{2}, \ldots, \binom{d}{d-1}, \binom{d}{d}$.

8. The eigenvalues of the line graph $L(K_n)$ are $2n-4$, $n-4$, and -2, with respective multiplicities 1, $n-1$, and $\frac{n(n-3)}{2}$.

9. The eigenvalues of the line graph $L(K_{m,n})$ are $m+n-2$, $m-2$, $n-2$, and -2, with respective multiplicities 1, $n-1$, $m-1$, and $(m-1)(n-1)$.

10. If G is strongly regular with parameters (n,k,r,s), then its eigenvalues are k and $\frac{1}{2}\big(r-s\pm\sqrt{(r-s)^2-4(s-k)}\,\big)$.

11. The smallest pair of cospectral graphs is $K_{1,4}$ and C_4+K_1, both with spectrum $\{-2,0,0,0,2\}$. See the following figure. Observe that $K_{1,4}$ is connected and that C_4+K_1 is not, and that the two graphs have different degree sequences. This implies that connectedness and degree sequences cannot be determined from spectral properties alone.



8.10.3 ALGEBRAIC GRAPHS AND AUTOMORPHISMS

Definitions:

A ***generating subset for a group*** Γ is a subset Σ of group elements such that every group element is a product of elements of Σ. (*Note*: The group identity is the empty product.)

The ***Cayley digraph for group*** Γ ***and generating set*** Σ has as vertices the elements of Γ, with an arc σ_γ from the vertex γ to the vertex γ' if and only if $\gamma\sigma=\gamma'$.

If Γ is a group and Σ a symmetric set (meaning $\gamma\in\Gamma$ if and only if $\gamma^{-1}\in\Gamma$), then the undirected ***Cayley graph*** for Γ and Σ is the graph obtained by removing all arc directions from the Cayley digraph, and by collapsing each opposite pairs of arcs to a single edge.

The ***Schreier graph*** [***Schreier digraph***] for a group $\mathcal{A}$ with generating set $x_1,\ldots,x_r$ and subgroup $\mathcal{B}$ has as its vertices the cosets of $\mathcal{B}$ in $\mathcal{A}$. For each coset $\mathcal{B}b$ and each generator x_j, there is an edge between vertices $\mathcal{B}b$ and $\mathcal{B}bx_j$ [from $\mathcal{B}b$ to $\mathcal{B}bx_j$].

An ***algebraic specification*** of a graph is a generalization of Cayley graphs and Schreier graphs. It uses elements of a group as all or part of the names of the vertices and edges, and the group operation in the incidence rule.

A ***voltage graph*** is a form of algebraic specification in which the vertices and edges are specified as a set of one or more symbols with subscripts, ranging over group elements. Its usual form is a digraph with vertex labels and edge labels.

The ***automorphism group*** $Aut(G)$ of a graph G is the set of all automorphisms of graph G, under the operation of functional composition. (See §8.5.1.)

A graph is ***vertex-transitive*** if for all vertices u and v there is an automorphism that maps u to v.

Facts:

1. Every Cayley graph is regular and vertex-transitive.

2. Every Cayley graph [digraph] is a Schreier graph [digraph].

3. A simple graph G and its edge-complement $\overline{G}$ have the same automorphism group.

4. An automorphism φ of a graph G induces an automorphism $\overline{\varphi}$ on the line graph $L(G)$.

5. If G is a connected simple graph with at least 4 vertices, then G and its line graph $L(G)$ have isomorphic automorphism groups.

6. If the G graph has adjacency matrix A, and if the permutation φ of V_G has permutation matrix P, then φ is the vertex map of an automorphism of G if and only if $PA = AP$.

7. If all eigenvalues of a graph G have multiplicity 1, then every automorphism has order at most 2.

8. *Frucht's theorem*: Let Γ be any finite group. Then there exists a graph G whose automorphism group is isomorphic to Γ. It can be constructed by modifying a Cayley digraph for Γ.

9. Every regular graph of even degree can be specified as a Schreier graph. (J. Gross, 1977)

10. The graph specified by a voltage graph is topologically a covering space of the voltage graph. (J. Gross, 1974)

Examples:

1. The n-vertex edgeless graph and the complete graph K_n have the symmetric group S_n as their automorphism group. They are the only n-vertex graphs with this automorphism group.

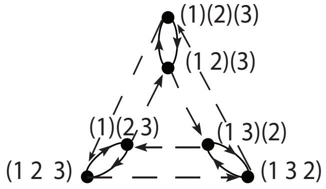
2. The automorphism group of the complete bipartite graph $K_{m,n}$ is $S_n \times S_m$ if $n \neq m$ and is the wreath product [Ro99] $S_n \wr S_2$ if $m = n$.

3. The automorphism group of the n-path P_n (with $n > 1$) is S_2.

4. The automorphism group of the n-cycle C_n is the dihedral group D_n of order $2n$. For instance, the 4-cycle C_4 with vertices a, b, c, and d (in cyclic order), has the following vertex automorphisms:

$$\begin{array}{llll} (a)(b)(c)(d) & (a\ \ b\ \ c\ \ d) & (a\ \ c)(b\ \ d) & (a\ \ d\ \ c\ \ b) \\ (a\ \ b)(c\ \ d) & (a\ \ d)(b\ \ c) & (a)(c)(b\ \ d) & (b)(d)(a\ \ c). \end{array}$$

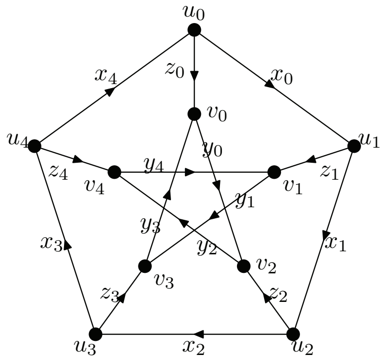
5. The Cayley digraph of the group S_3 with generating set $\{(1\ 2\ 3), (1\ 2)\}$ is illustrated in the following figure.

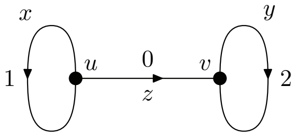


6. The Petersen graph is an example of a graph that is vertex-transitive but not a Cayley graph. It has the following algebraic specification:

$$V = \{v_j, w_j \mid j = 0, 1, 2, 3, 4\};$$
$$E = \{x_j\ (u_j \to u_{(j+1)\ \mathbf{mod}\ 5}),\ y_j\ (v_j \to v_{(j+2)\ \mathbf{mod}\ 5}),\ z_j\ (u_j \to v_j) \mid j = 0, 1, 2, 3, 4\}.$$

With appropriate labeling, it corresponds to the voltage graph on the right.





8.10.4 EXPANDER GRAPHS

Expander graphs are sparse graphs where every small set of vertices is well-connected to the rest of the graph. For more information on expander graphs, and for proofs of facts stated below, see [HoLiWi06], [KrSh11], [Lu94], and the references contained within. All graphs in this subsection are finite and undirected.

Definitions:

If F is a subset of vertices in a graph, the ***boundary*** of F, denoted by ∂F, is the set of edges that have one endpoint inside F and one endpoint outside F.

The ***isoperimetric constant*** of graph X with vertex set V is defined as

$$h(X) = \min \left\{ \frac{|\partial F|}{|F|} \mid F \subseteq V,\ 0 < |F| \leq |V|/2 \right\}.$$

It is also known as the Cheeger constant or expansion constant of X.

An ***expander family*** is a sequence (X_n) of graphs, all of the same regularity and whose orders grow to infinity, for which there exists $\epsilon > 0$ such that $h(X_n) \geq \epsilon$ for all n.

The ***eigenvalues*** of graph G are the eigenvalues of its adjacency matrix A_G. (See §8.10.2.) Since A_G is symmetric, all its eigenvalues are real. We use the convention that $\lambda_1(X) \geq \lambda_2(X) \geq \cdots \geq \lambda_n(X)$.

If X is a d-regular graph, then the ***spectral gap*** of X is $d - \lambda_2(X)$.

If X is a regular graph of order n, we define $\lambda(X)$ as $\max\{|\lambda_2(X)|, |\lambda_n(X)|\}$ if X is not bipartite, and $\max\{|\lambda_2(X)|, |\lambda_{n-1}(X)|\}$ if X is bipartite.

A d-regular graph X is ***Ramanujan*** if $\lambda(X) \leq 2\sqrt{d-1}$.

Let G be a finite group and let Γ be a subset of G. Given a finite-dimensional unitary representation $\pi\colon G \to GL(V)$ of G, define $\kappa(G, \Gamma, \pi)$ to be the minimum, over all unit vectors $v \in V$ and all $\gamma \in \Gamma$, of the quantity $\|\pi(\gamma)v - v\|$. The ***Kazhdan constant*** of the pair (G, Γ), denoted by $\kappa(G, \Gamma)$, is defined to be the minimum, over all nontrivial irreducible unitary representations π of G, of $\kappa(G, \Gamma, \pi)$.

Facts:

1. Expander graphs are used in the design of algorithms, computer networks, and error-correcting codes, as well as in cryptography. They have also been used inside proofs of complexity theory results.

2. If X is a d-regular graph, then

$$\frac{d-\lambda_2(X)}{2} \leq h(X) \leq \sqrt{(d+\lambda_2(X))(d-\lambda_2(X))}.$$

3. Let (X_n) be a sequence of d-regular graphs with $|X_n| \to \infty$. Then (X_n) is an expander family if and only if there exists $\epsilon > 0$ such that the spectral gap is at least ϵ for all n.

4. Let (X_n) be a sequence of d-regular Ramanujan graphs with $d \geq 3$ and $|X_n| \to \infty$. Then (X_n) is an expander family.

5. There exist infinite families of regular bipartite Ramanujan graphs of every degree bigger than 2. (Marcus, Spielman, Srivastava, 2015).

6. Let (X_n) be a sequence of d-regular graphs with $|X_n| \to \infty$. Then for all $\epsilon > 0$ there is some X_n with $\lambda(X_n) > 2\sqrt{d-1} - \epsilon$. That is, the bound given in the definition of Ramanujan graphs cannot be lowered.

7. Let d be a positive integer and let (G_n) be a sequence of finite groups with $|G_n| \to \infty$. For each n, let X_n be an (undirected) Cayley graph for G_n with generating set Γ_n chosen so that X_n is d-regular. (See §8.10.3.) Then (X_n) forms an expander family if and only if there exists $\epsilon > 0$ such that $\kappa(G_n, \Gamma_n) \geq \epsilon$ for all n. (It is known that this cannot hold if all the groups are abelian.)

8. Let $d \geq 3$ and let $0 < \alpha < 1$ be a real number such that $2^{4/d} < (1-\alpha)^{1-\alpha}(1+\alpha)^{1+\alpha}$. In a certain random graph model, as $n \to \infty$, the probability that $h(X) \geq (1-\alpha)d/2$ for a randomly chosen d-regular graph X of order n goes to 1.

9. Let d be a positive integer and $\epsilon > 0$. In a certain random graph model, as $n \to \infty$, the probability that $\lambda_2(X) \leq 2\sqrt{d-1} + \epsilon$ for a randomly chosen d-regular graph X of order n goes to 1.

Examples:

1. Let $X = (V_X, E_X)$ and $Y = (V_Y, E_Y)$ be regular graphs, where the degree of X equals the order of Y. In this example, multiple edges and loops are allowed, and multiple edges are treated as distinct elements. For each v from V_X, define the set E_v consisting of all edges $e \in E_X$ incident to v, and choose some bijection $L_v \colon V_Y \to E_v$. Define the ***zig-zag product*** $X \textcircled{z} Y$ to be the graph with vertex set $V_X \times V_Y$ where the number of edges between (x_1, y_1) and (x_2, y_2) is equal to the number of ordered pairs $(z_1, z_2) \in E_Y \times E_Y$ such that y_1 is an endpoint of z_1, y_2 is an endpoint of z_2, and $L_{x_1}(z_1(y_1)) = L_{x_2}(z_2(y_2))$.

2. If G is a graph with adjacency matrix A, we denote by G^2 the graph with adjacency matrix A^2. Let W be a nonbipartite d-regular graph of order d^4 with $\lambda(W)/d \leq 1/5$. (It can be shown that such a graph W exists.) Define the sequence W_n by $W_1 = W^2$ and $W_{n+1} = W_n^2 \textcircled{z} W$. Then the sequence of graphs (W_n) forms an expander family.

3. Construct a family (X_n) of 8-regular graphs as follows. Let the vertex set of X_n be $\mathcal{Z}_n \times \mathcal{Z}_n$. Let the neighbors of (x, y) be the vertices $(x, y+2x)$, $(x+2y, y)$, $(x, y+2x+1)$, $(x+2y+1, y)$, $(x, y-2x)$, $(x-2y, y)$, $(x, y-2x-1)$, and $(x-2y-1, y)$ (arithmetic modulo n). Then $\lambda(X_n) \leq 5\sqrt{2} < 8$. Hence, (X_n) is an expander family by Fact 3.

8.10.5 PRODUCT GRAPHS

Graph products provide a convenient language for the description of structures, but they are also algebraic objects with deep results and challenging open problems. Here we describe only the four standard products, although there are many other products that are useful for special purposes, e.g., in the construction of expanders. For more information consult the handbook [HaImKl11].

Definitions:

Given graphs G and H, the ***Cartesian product*** $G \,\Box\, H$, the ***direct product*** $G \times H$, the ***strong product*** $G \boxtimes H$, and the ***lexicographic product*** $G \circ H$ have as vertex sets the Cartesian product $V(G) \times V(H)$. Edges are as follows:

$$\begin{aligned} E(G \,\Box\, H) &= \big\{(g,h)(g',h') \mid gg' \in E(G) \text{ and } h = h', \text{ or, } g = g' \text{ and } hh' \in E(H)\big\}, \\ E(G \times H) &= \big\{(g,h)(g',h') \mid gg' \in E(G) \text{ and } hh' \in E(H)\big\}, \\ E(G \boxtimes H) &= E(G \,\Box\, H) \cup E(G \times H), \\ E(G \circ H) &= \big\{(g,h)(g',h') \mid gg' \in E(G), \text{ or } g = g' \text{ and } hh' \in E(H)\big\}. \end{aligned}$$

If $\bullet \in \{\,\Box\,, \boxtimes, \times, \circ\}$ and $A = G \bullet H$, then G and H are ***factors*** of A with respect to $\bullet$.

If a graph cannot be represented as a product $G\bullet H$ of two graphs on at least two vertices each, then it is ***prime*** with respect to $\bullet$.

Facts:

1. The standard products are associative in the sense that the map $((g,h),k) \mapsto (g,(h,k))$ is an isomorphism $(G \bullet H) \bullet K \to G \bullet (H \bullet K)$.

2. The Cartesian, direct, and strong products are commutative. In general $G \circ H$ and $H \circ G$ are not isomorphic.

3. If $G \circ H$ and $H \circ G$ are isomorphic, then G and H are either both complete, both edgeless, or both lexicographic powers of the same graph X.

4. If $+$ represents disjoint union, then $G \bullet (H + K) = G \bullet H + G \bullet K$ for each of the standard products.

5. The one-vertex graph K_1 is a unit for the Cartesian, the strong and the lexicographic products; that is, $G = G \,\Box\, K_1 = G \boxtimes K_1 = G \circ K_1$ for any graph G.

6. The direct product has no unit in the class of simple graphs. If one allows loops, then its unit is the one-vertex graph with a loop.

7. The Cartesian and the strong products of two graphs are connected if and only if both factors are connected.

8. The direct product of two graphs is connected if and only if both factors are connected and at most one is bipartite.

9. If G is nontrivial, then $G \circ H$ is connected if and only if G is connected. (But if $G = K_1$, then $G \circ H$ is connected if and only if H is connected.)

10. Every nontrivial connected graph has a unique representation as a Cartesian product of prime graphs, up to isomorphisms and the order of the factors. The same result holds for the strong product.

11. Unique prime factorization over the direct product involves the class Γ_0 of finite graphs that admit loops. Every connected nonbipartite graph on more than one vertex factors uniquely (up to isomorphism and the order of the factors) into primes with respect to the direct product in Γ_0.

12. Although connected bipartite graphs do not necessarily factor uniquely into primes, such a factoring always contains exactly one prime bipartite factor, which is unique. (R. Hammack and O. Puffenberger, 2015)

13. Despite the fact that prime factorization over the direct product need not be unique for bipartite graphs, we have the following cancellation laws:
(i) If $G \times H$ is isomorphic to $G' \times H$ and G, G', H are bipartite, then G is isomorphic to G'.
(ii) If $G \times H$ is isomorphic to $G' \times H$ and H has an odd cycle, then G is isomorphic to G'.
In general, $G \times H$ being isomorphic to $G' \times H$ requires that $V(G') = V(G)$ and $E(G') = \{x\alpha(y) \mid xy \in E(G)\}$, where α is a permutation of $V(G)$ satisfying $\alpha(x)\alpha^{-1}(y) \in E(G)$ for all $xy \in E(G)$.

14. A Cartesian, strong, direct, or lexicographic product has a transitive automorphism group if and only if every factor has a transitive automorphism group.

15. Given a connected graph of order n and size m, its prime factors over the Cartesian product can be computed in time $O(m)$.

16. Given a connected graph, its prime factors over the strong product can be computed in time $O(ma\Delta)$, where m is the size, a the arboricity, and Δ the maximum degree.

17. Over the direct product, the prime factors of a connected nonbipartite graph of order n, size m, and maximum degree Δ can be computed in $O(m \min(n^2, \Delta^3))$ time.

18. The problem of finding a nontrivial factoring of a graph over the lexicographic product is polynomially equivalent to the graph isomorphism problem.

19. The automorphism group of a connected graph is isomorphic to the automorphism group of the disjoint union of its prime factors over the Cartesian product. The same holds: (i) For the strong product, if in addition no two vertices of the graph have identical closed neighborhoods. (ii) For the direct product (in the class Γ_0 of finite graphs that admit loops), if the graph is nonbipartite and no two vertices have identical open neighborhoods.

20. If G and H are graphs on at least two vertices, then the connectivity $\kappa(G \,\Box\, H)$ is $\min\{\kappa(G)|V(H)|, \kappa(H)|V(G)|, \delta(G) + \delta(H)\}$.

Open problems:

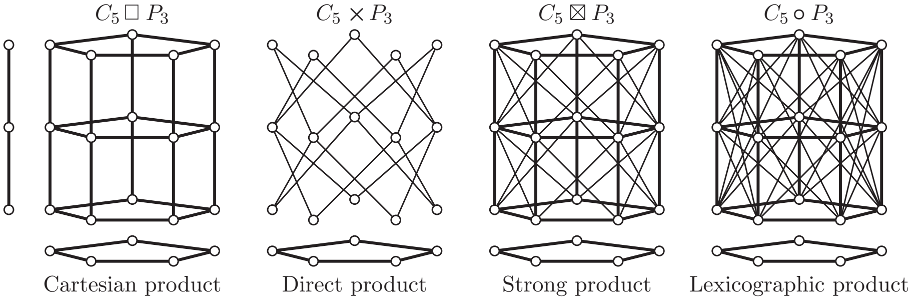
1. *Hedetniemi's conjecture*: $\chi(G \times H) = \min\{\chi(G), \chi(H)\}$, where χ is the chromatic number. This is only known to be true if G or H has chromatic number up to 4. (See §8.6.1)

2. *Vizing's conjecture*: $\gamma(G \,\Box\, H) \geq \gamma(G)\gamma(H)$, where γ is the domination number. (See §8.6.6.)

3. *Graham's conjecture*: $p(G \,\Box\, H) \leq p(G)p(H)$, where p is the pebbling number. (See §8.6.7.)

Examples:

1. The figure below shows the four products whose factors are the five-cycle and the path of length two.



2. *Hamming graphs* are Cartesian products of complete graphs. Thus hypercubes are Hamming graphs where every factor is a K_2.

3. Some direct products can be represented as Cartesian products. For example, $K_2 \times K_4 = Q_3$, $C_{2k+1} \times C_{2k+1} = C_{2k+1} \,\square\, C_{2k+1}$, and $K_m \times K_n$ is the complement of $K_m \,\square\, K_n$.

4. A *median graph* is a graph with the property that for any three vertices u, v, w, there is exactly one vertex z that is on a shortest u,v-path, a shortest v,w-path, and a shortest w,u-path. These graphs play a role in genetics. Every median graph is the ***retract*** of an hypercube: that is, the image of an adjacency-preserving mapping α of some hypercube into itself, where $\alpha^2 = \alpha$.

5. Large powers of (small) graphs with respect to the direct product can be used to model the internet graph and similar networks.

6. The *Shannon capacity* of a graph G is the limit as $n \to \infty$ of the nth root of the independence number of the strong product of n copies of G. It measures the amount of information involving an alphabet $V(G)$ that can be accurately transmitted across a channel, where $E(G)$ is the set of pairs of symbols that are easily "confoundable" in transmission.

7. If $G = \Gamma(A, S)$ and $G' = \Gamma(A', S')$ are Cayley graphs, where A and A' are groups with generating sets S and S', then $G \circ G'$ is the Cayley graph $\Gamma\big(A \times A', (\{1\} \times S') \cup (S \times A')\big)$.

8.11 ANALYTIC GRAPH THEORY

Analytic graph theory involves three different perspectives on the properties of graphs that are sufficiently "dense". One analysis is what must happen in a simple graph when the number of edges is sufficiently large. A second analysis is what must happen in at least one of the parts of a partition of the edges of a graph. The third analysis is what happens with a high probability when a graph is randomly chosen according to some distribution.

8.11.1 EXTREMAL GRAPH THEORY

We focus on the part of extremal graph theory that investigates the number of edges an n-vertex simple graph must have in order to guarantee that it contains a certain graph or type of graph.

Definitions:

The ***extremal number*** $ex(\mathcal{G}; n)$ for a set $\mathcal{G}$ of graphs is the greatest number of edges in any simple graph with n vertices that does *not* contain some member of $\mathcal{G}$ as a subgraph. Also, the notation $ex(G; n)$ is used when $\mathcal{G}$ consists of just one graph G.

An ***extremal graph*** for a set $\mathcal{G}$ of graphs and an integer n is a graph with n vertices and $ex(\mathcal{G}; n)$ edges that contains no member of $\mathcal{G}$.

The ***Turán graph*** $T_k(n)$ is the n-vertex k-partite simple graph with the maximum number of edges.

The ***Turán number*** $t_k(n)$ is the number of edges in the Turán graph $T_k(n)$.

Facts:

1. If $ex(\mathcal{G};n) = \binom{n}{2}$, then no graph with n vertices contains any member of $\mathcal{G}$.

2. The Turán graph $T_k(n)$ is the unique complete k-partite graph with the property that the numbers of vertices in any two of its parts differ by at most 1. In the special case $k = 2$, $T_2(n) = K_{\lfloor n/2 \rfloor, \lceil n/2 \rceil}$. More generally, if $n = tk + r$, where $0 \le r < k$, then there are r parts of size $t + 1$ and $k - r$ parts of size t.

3. The Turán number $t_k(n)$ equals $\binom{n}{2} - \frac{t(n-k+r)}{2}$, where $n = tk + r$, with $0 \le r < k$. If $k = 2$, this simplifies: $t_2(n) = \lfloor \frac{n^2}{4} \rfloor$.

4. *Turán's theorem*: $ex(K_k; n) = t_{k-1}(n)$; furthermore, $T_{k-1}(n)$ is the only extremal graph for K_k and n.

5. Let $\chi = \chi(G)$ (chromatic number of G, §8.6.1) and $p = |G|$. Then $ex(G;n)$ is given by $\left(1 - \frac{1}{\chi-1}\right)\binom{n}{2} + O(n^{2-1/p})$. Furthermore, all the extremal graphs differ from the Turán graph $T_{\chi-1}(n)$ by adding and deleting $O(n^{2-1/p})$ edges, and the minimum degree of all such graphs is $(1 - \frac{1}{\chi-1})n + O(n^{2-1/p})$. (Erdős, Simonovits)

6. Fact 5 is also true for $ex(\mathcal{G};n)$, where χ is the smallest chromatic number among the members of $\mathcal{G}$, and p is the smallest order among these members.

7. $ex(\mathcal{G};n) = O(n)$ if and only if $\mathcal{G}$ contains a (tree or) forest.

8. There exists a number t_0 such that, for $t > t_0$, every tree T of order t satisfies the inequality $ex(T;n) \le \frac{n(t-2)}{2}$ for every $n \ge t + 1$.

9. $ex(C_4;n) = \frac{1}{2}(n^{3/2}) + O(n^{4/3})$. (The exponent $\frac{4}{3}$ can be slightly improved.)

10. $ex(C_{2m};n) = O(n^{1+1/m})$. This is known to be sharp only for $2m = 4, 6, 10$, but is conjectured to be sharp for all m.

11. The ratio $\frac{ex(\mathcal{G};n)}{\binom{n}{2}}$ is monotone nonincreasing; that is, for every set $\mathcal{G}$ and for all $m \le n$, $\frac{ex(\mathcal{G};m)}{\binom{m}{2}} \ge \frac{ex(\mathcal{G};n)}{\binom{n}{2}}$.

12. The following table summarizes some facts that apply as the number of edges grows.

# edges	*what must occur, but not for smaller # edges*	*what must occur if n is large enough*
n	some cycle	
$\lfloor \frac{3n-1}{2} \rfloor$	some even cycle	
$3n - 5$	two disjoint cycles	
$t_2(n) + 1 = \lfloor \frac{n^2}{4} \rfloor + 1$	some odd cycle (i.e., $\chi \ge 3$), $C_3, \ldots, C_{\lfloor (n+3)/2 \rfloor}$	$K_{s,s} + e$ for fixed s
$t_2(n) + m$, m fixed		$m\lfloor \frac{n}{2} \rfloor$ copies of C_3; for fixed s $K_{s,s}$ plus m extra edges
$t_k(n) + 1$	K_k; also, $\chi \ge k$	
$t_k(n) + m$, m fixed		for fixed s, $K_{s,n}$ plus m extra edges
$\binom{n}{2} - n + 3$	a Hamilton cycle	

Examples:

1. $ex(K_2;n) = 0$. The extremal graph is the edgeless graph.

2. $ex(P_2;n) = \lfloor \frac{n}{2} \rfloor$. The extremal graph is a perfect matching.

3. $ex(K_{1,r};n) = \lfloor\frac{(r-1)n}{2}\rfloor$. If $(r-1)n$ is even, then any $(r-1)$-regular graph is an extremal graph. If $(r-1)n$ is odd, then any graph with one vertex of degree $r-2$ and all the others of degree $r-1$ is extremal.

4. $ex(K_3;n) = \lfloor\frac{n^2}{4}\rfloor$. The Turán graph $T_2(n)$ is the only extremal graph.

5. The Turán graph $T_3(10)$ is the 3-partite graph $K_{3,3,4}$. It has 33 edges, which is more than any other 3-partite graph on 10 vertices. Thus, $ex(K_4;10) = 33$.

8.11.2 RAMSEY THEORY FOR GRAPHS

If the edges of a "dense" graph are partitioned into two parts, then at least one of the parts must still be fairly dense. Ramsey theory, which can also be studied in connection with many mathematical objects other than graphs, relies on this idea. (Also see §3.1.6.)

Definitions:

The (***classical***) ***Ramsey number*** $r(m,n)$ is the smallest positive integer k such that every k-vertex graph contains either the complete graph K_m or n mutually nonadjacent vertices.

The ***Ramsey number*** $r(G,H)$ is the smallest positive integer k such that, if the edges of K_k are partitioned into red and blue classes, then either the red subgraph contains a copy of G or else the blue subgraph contains a copy of H. Sometimes $r(G)$ denotes $r(G,G)$.

The ***Ramsey number*** $r(G_1,\ldots,G_s)$ is the smallest number k such that in any s-fold partition of the edgeset of K_k, there is an index j such that the jth part contains the graph G_j.

A ***k-canonical coloring*** of a complete graph is an edge-coloring in which the vertices can be partitioned into k or fewer parts, such that the color of each edge depends only on the two parts to which its endpoints belong.

The ***arrows notation*** $\boldsymbol{F \to (G,H)}$ ("F arrows (G,H)") means that if the edges of the graph F are partitioned into red edges and blue edges, then either the red subgraph contains a copy of G or else the blue subgraph contains a copy of H. When $G=H$, the notation $F \to G$ is used. The notation $F \to (G_1,\ldots,G_k)$ means that k edge colors are involved.

Facts:

1. $r(K_m,K_n) = r(m,n)$.

2. $r(G,H) = r(H,G)$. That is, Ramsey numbers are symmetric.

3. $r(K_n,K_1) = r(K_1,K_n) = 1$ for every $n \geq 1$.

4. $r(K_n,K_2) = r(K_2,K_n) = n$ for every $n \geq 1$.

5. $r(K_m,K_n) \leq r(K_m,K_{n-1}) + r(K_{m-1},K_n)$ for all $m,n \geq 2$.

6. $r(K_m,K_n) \leq \binom{m+n-2}{m-1}$. (Erdős and Szekeres, 1935)

7. If $n \geq 3$, then $2^{n/2} \leq r(K_n,K_n) \leq \binom{2n-2}{n-1} < 4^n$.

8. The previous fact can be improved: $O(n2^{n/2}) \leq r(K_n,K_n) \leq \binom{2n-2}{n-1} \cdot O(1/\log n)$.

9. There exist constants c_1 and c_2 such that $c_1 n \ln n \leq r(K_3,K_n) \leq c_2 n \ln n$.

10. A 1-canonical coloring assigns every edge the same color.

11. A 2-canonical coloring consists of two complete edge-monochromatic subgraphs, such that all edges joining them are of the same color.

12. If $\chi(G) = \chi$ and $|V_H| = n$, then $r(G, H) \geq (\chi - 1)(n - 1) + 1$. This fact is based on a $(\chi - 1)$-canonical coloring.

13. If T is an n-vertex tree, then $r(K_m, T) = (m - 1)(n - 1) + 1$. In other words, the lower bound in the immediately preceding fact determines the Ramsey number.

14. Except for $r(C_3, C_3) = r(C_4, C_4) = 6$, the Ramsey numbers $r(C_m, C_n)$ and $r(P_m, C_n)$ are determined by the best possible 2-canonical colorings, which are easy to find.

15. For every choice of graphs $G_1, G_2, \ldots, G_k$, there exists a graph F for which $F \to (G_1, \ldots, G_k)$. In particular, the Ramsey number $r(G_1, \ldots, G_k)$ is well defined.

16. If $m, n \geq 3$, the values of only nine classical Ramsey numbers are known:

$$\begin{array}{lll} r(3,3) = 6 & r(3,4) = 9 & r(3,5) = 14 \\ r(3,6) = 18 & r(3,7) = 23 & r(3,8) = 28 \\ r(3,9) = 36 & r(4,4) = 18 & r(4,5) = 25. \end{array}$$

17. Estimates on some other Ramsey numbers are given in §3.1.6. In addition to the nine exact results, only one other nontrivial Ramsey number for complete graphs is known:

$$r(K_3, K_3, K_3) = 17.$$

8.11.3 PROBABILISTIC GRAPH THEORY

Probabilistic graph theory takes two basic directions. It studies random graphs for themselves, and it uses random graphs in deriving graph-theoretical results that are not themselves probabilistic.

Definitions:

In ***Model 1***, the ***random graph*** $G_{n,p}$ has n labeled vertices $v_1, \ldots, v_n$, and the probability of any pair of vertices being joined by an edge is p, where all these edge probabilities are mutually independent.

In ***Model 2***, the ***random graph*** $G_{n,e}$ has n labeled vertices $v_1, \ldots, v_n$, and exactly e edges, and each such labeled graphs occurs with the same probability $1/\binom{N}{e}$, where $N = \binom{n}{2}$.

We say ***almost every*** (**a.e.**) ***graph*** has some property P under either Model 1 or Model 2, if the probability that a random graph has property P approaches 1 as $n \to \infty$; where the probability p stays constant under Model 1, but how e varies with n under Model 2 must be specified. If no model is explicitly specified, then Model 1 with $p = 1/2$ is implicit.

Facts:

1. The number of labeled graphs in the probability space for Model 1 is $2^{\binom{n}{2}}$.

2. While Model 2 is sometimes considered more natural, it is in practice usually easier to work with Model 1. Fortunately, Model 1 with $p = \frac{e}{N}$ behaves very similarly to Model 2 in most cases, so that facts about Model 1 usually lead easily to facts about Model 2 as well.

3. In Model 1, a graph with e edges occurs with probability $p^e(1-p)^{\binom{n}{2}-e}$. If $p = 1/2$, then every labeled graph on n vertices has the same probability $2^{-\binom{n}{2}}$.

4. Random graphs can be used to prove theorems about graphs, especially existence theorems. (See Example 1.)

5. Let $b = \frac{1}{p}$ and $d = 2\log_b \frac{en}{2\log_b n} = 1$, where $e = 2.718\ldots$, not the number of edges. Then for every positive $\epsilon < \frac{1}{2}$ the clique number of a.e. graph is either $\lfloor d-\epsilon \rfloor$ or $\lfloor d+\epsilon \rfloor$, where these two values are usually the same when ϵ is small. This means that the clique number is determined for a.e. graph, unless d is close to an integer, in which case there are two possible values.

6. If $p \gg 1/n$ (for example if p is constant), the chromatic number of $G(n,p)$ is

$$\left(\tfrac{1}{2} + o(1)\right) \frac{n}{\log_2(np)} \log_2\left(\tfrac{1}{1-p}\right).$$

7. Moreover, if $p = n^{-\alpha}$ for fixed $\alpha > 1/2$, then in Model 1, there exists an $f(n,p)$ so that for almost every graph, $f(n,p) \le \chi \le f(n,p)+1$. That is, the chromatic number χ takes on one of two consecutive values.

8. Almost every graph in Model 1 has its connectivity and its edge connectivity equal to its minimum degree. Furthermore, the common value of these three parameters is $pn - (2p(1-p)n\log n)^{\frac{1}{2}} + o(n\log n)^{\frac{1}{2}}$.

9. Generating a random graph $G_{n,p}$ under Model 1 is straightforward, as indicated by Algorithm 1.

```
Algorithm 1: Generate random graph $G_{n,p}$ (per Model 1).
  initialize graph with vertex list $v_1, v_2, \ldots, v_n$
  for $i := 1$ to $n-1$
    for $j := i+1$ to $n$
      join vertices $v_i$ and $v_j$ with probability $p$
```

10. To generate a random graph $G_{n,e}$ under Model 2, the possible edges are placed in bijective correspondence with the integers $1,\ldots,\binom{n}{2}$ according to the rule $f(i,j) = \binom{n}{2} - \binom{n-i+1}{2} + j$. Also, the e-combinations of the integers $1,\ldots,\binom{n}{2}$ are placed in bijective correspondence with the integers $1,\ldots,\binom{\binom{n}{2}}{e}$ according to the lexicographic ordering of those e-combinations (see §2.3.5). This yields Algorithm 2.

```
Algorithm 2: Generate random graph $G_{n,e}$ (per Model 2).
  initialize graph with vertex list $v_1, v_2, \ldots, v_n$
  generate random integer $r \in \left\{1,\ldots,\binom{\binom{n}{2}}{e}\right\}$
  convert $r$ to an $e$-combination $C$ in $\left\{1,\ldots,\binom{n}{2}\right\}$
  convert $e$-combination $C$ to $e$ edges in $G_{n,e}$
```

11. For every fixed s, almost every graph contains the complete graph K_s. Moreover, for every fixed graph H, almost every graph contains H.

12. Here is a table of some properties of almost every n-vertex graph:

p under Model 1	*e under Model 2*	*property of almost every graph*
$o(\frac{1}{n})$	$o(n)$	no cycles
$\frac{2c}{n},\ 0 < c < \frac{1}{2}$	$cn,\ 0 < c < \frac{1}{2}$	cycles are possible, and the largest component has order $\approx \ln n$
$\frac{1}{n}$	$\frac{n}{2}$	some cycle exists, and the largest component has order $\Theta(n^{2/3})$
$\frac{2c}{n},\ \ c > \frac{1}{2}$	$cn,\ \ c > \frac{1}{2}$	the largest component has order $c'n$
$\frac{c \ln n}{n},\ \ c < 1$	$\frac{c}{2} n \ln n,\ \ c < 1$	the graph is disconnected
$\frac{c \ln n}{n},\ \ c > 1$	$\frac{c}{2} n \ln n,\ \ c > 1$	the graph is connected and Hamiltonian

Examples:

1. *Using random graphs to prove theorems*: Here is a proof that the Ramsey number $r(K_n, K_n)$ (see §8.11.2) is greater than $2^{n/2}$ for all $n \geq 3$. Consider a random red-blue edge-coloring of K_N for some $N > n$ with $p(\mathit{red}) = 1/2$. The probability that any given K_n occurring within this 2-colored K_N is entirely red is $2^{-\binom{n}{2}}$. Of course, the probability that it is colored blue is the same. Thus, the probability that the given subgraph K_n is monochromatic in either color is $2^{1-\binom{n}{2}}$. Since there are $\binom{N}{n}$ different copies of K_n in the colored K_N, the expected number of monochromatic K_n is $\binom{N}{n} \cdot 2^{1-\binom{n}{2}}$.

With the choice of $N = \lfloor 2^{n/2} \rfloor$, this expectation is $\binom{N}{n} \cdot 2^{1-\binom{n}{2}} < \frac{2^{1+n/2}}{n!} \cdot \frac{N^n}{2^{n^2/2}} < 1$, i.e., less than 1. Therefore there must be some coloring with no monochromatic K_n at all.

2. Other examples in which random graphs are analyzed can be found in the section on the probabilistic method (see §7.11).

8.12 HYPERGRAPHS

In ordinary graph theory, an edge of a simple graph can be regarded as a pair of vertices. In hypergraph theory, an "edge" can be regarded as an arbitrary subset of vertices. In this sense, hypergraphs are a natural generalization of graphs. Their systematic study was initiated by C. Berge. They have evolved into a unifying combinatorial concept.

8.12.1 HYPERGRAPHS AS A GENERALIZATION OF GRAPHS

Definitions:

A ***hypergraph*** $H = (V, E)$ is a finite set V of "vertices" together with a finite multiset E of "edges" (sometimes, "hyperedges"), which are arbitrary subsets of V.

The ***order*** of a hypergraph edge is its cardinality.

A ***partial hypergraph*** (or simply a ***partial***) of the hypergraph $H = (V, E)$ is a hypergraph $H' = (V, E')$ such that $E' \subseteq E$. This generalizes a spanning subgraph.

A hypergraph $H = (V, E)$ is ***simple*** if E has no repeated edges.

The ***incidence matrix*** of a hypergraph $H = (V, E)$ with $E = \{e_1, e_2, \ldots, e_m\}$ and $V = \{x_1, x_2, \ldots, x_n\}$ is the $m \times n$ matrix $M(H) = [m_{i,j}]$ with $m_{i,j} = 1$ if $x_j \in e_i$ and 0 otherwise.

The ***dual hypergraph*** of the hypergraph H is the hypergraph H^* whose incidence matrix is the transpose of the incidence matrix $M(H)$. This concept of duality from block design theory differs from the dual of a graph embedded on a surface.

The ***degree*** $\deg(x)$ of a hypergraph vertex x is the number of hypergraph edges containing x.

A hypergraph is ***regular*** if all vertices have the same degree. If t is the common value of the degrees, then the hypergraph is ***t-regular***.

A hypergraph is ***uniform*** if all edges have the same number of vertices. If r is the common value, then the hypergraph is ***r-uniform***.

The ***complete hypergraph*** K_n^* has all subsets of n vertices as edges, so that it has 2^n edges.

The ***complete r-uniform hypergraph*** K_n^r is the simple hypergraph of order n with all r-element subsets as edges, so that it has $\binom{n}{r}$ edges.

The ***intersection graph*** $I(H)$ of the hypergraph H is a simple graph whose vertices are the edges of H. Two vertices of $I(H)$ are adjacent if and only if the corresponding edges of H have nonempty intersection.

An ***independent set*** of vertices in a hypergraph is a set of vertices that does not (completely) contain any edge of the hypergraph.

Facts:

1. *How to draw a hypergraph*: First draw the vertices and the hyperedges of order 2, as if they were vertices and edges, respectively, of a graph. Then shade triangular regions corresponding to hyperedges of order 3. Higher-order hyperedges and hyperedges of order 1 can be indicated by drawing enclosures around their vertices.

2. Every hypergraph satisfies the generalized Euler equation for degree-sum:

$$\sum_{x \in V} \deg(x) = \sum_{e \in E} |e|.$$

3. Every simple graph is a 2-uniform simple hypergraph.

4. The intersection graph of a hypergraph generalizes the line graph $L(G)$ of a graph G. (See §8.1.2.)

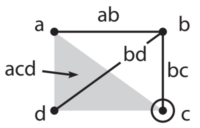
5. Every graph is the intersection graph of some hypergraph.

6. Every graph of order n is isomorphic to the intersection graph of a hypergraph of order at most $\lfloor n^2/4 \rfloor$.

7. When a graph G is regarded as a hypergraph, its dual is a hypergraph whose intersection graph is G.

Examples:

1. The hypergraph $H = (V, E)$ with $V = \{a, b, c, d\}$ and $E = \{ab, bc, bd, acd, c\}$ can be illustrated as follows:



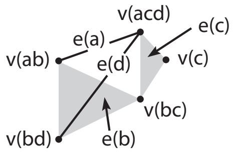
2. The hypergraph of Example 1 has the following incidence matrix:

$$\begin{array}{c|cccc} & a & b & c & d \\ ab & 1 & 1 & 0 & 0 \\ acd & 1 & 0 & 1 & 1 \\ bc & 0 & 1 & 1 & 0 \\ bd & 0 & 1 & 0 & 1 \\ c & 0 & 0 & 1 & 0 \end{array}$$

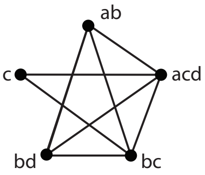
3. The dual of the hypergraph of Example 1 has the following incidence matrix:

$$\begin{array}{c|ccccc} & v\,(ab) & v\,(acd) & v\,(bc) & v\,(bd) & v\,(c) \\ e\,(a) & 1 & 1 & 0 & 0 & 0 \\ e\,(b) & 1 & 0 & 1 & 1 & 0 \\ e\,(c) & 0 & 1 & 1 & 0 & 1 \\ e\,(d) & 0 & 1 & 0 & 1 & 0 \end{array}$$

This dual hypergraph may be illustrated as follows:



4. The hypergraph of Example 1 has the following intersection graph:



8.12.2 HYPERGRAPHS AS GENERAL COMBINATORIAL STRUCTURES

Definitions:

A ***transversal*** (or ***cover*** or ***blocking set***) in a hypergraph is a set of vertices that has nonempty intersection with every edge of the hypergraph.

A ***system of distinct representatives*** (***SDR***) in a hypergraph $H = (V, E)$ with $E = \{e_1, e_2, \ldots, e_m\}$ is a transversal of m distinct vertices $x_1, x_2, \ldots, x_m$ such that $x_i \in e_i$ for $i = 1, \ldots, m$.

Hall's condition on a hypergraph is that, for each $t = 1, \ldots, m$ the union of every subset of t edges have at least t vertices. Thus, each partial must have at least as many vertices as edges.

A ***matching*** in a hypergraph is a set of pairwise disjoint edges.

An ***antichain*** is a hypergraph in which no edge contains any other edge.

A ***chain*** is a simple hypergraph in which, given any pair of edges, one edge contains the other.

A ***symmetric chain*** in an n-vertex hypergraph H is a chain with edges of order $\frac{n}{2} - t, \ldots, \frac{n}{2} + t$ for some $t \geq 0$.

A ***downset*** (or ***ideal***) is a simple hypergraph in which every subset of every edge is also an edge of the hypergraph.

An ***upset*** (or ***filter***) is a simple hypergraph in which every superset of every edge is also an edge of the hypergraph.

A ***hypergraph clique*** is a simple hypergraph such that every pair of edges has nonempty intersection.

An ***r-partite*** hypergraph is an r-uniform hypergraph whose vertex set can be partitioned into r blocks such that each edge intersects each block in exactly one vertex.

A hypergraph is ***unimodular*** if the determinant of every square submatrix of its incidence matrix is equal to 0, 1, or -1.

A hypergraph is an ***interval hypergraph*** if its n vertices can be labeled $1, 2, \ldots, n$ so that each edge is labeled by consecutive numbers.

Facts:

1. Hall's condition is necessary and sufficient for the existence of an SDR in a hypergraph.

2. *Sperner's lemma*: If the hypergraph H with n vertices and m edges is an antichain, then $m \leq \binom{n}{\lfloor n/2 \rfloor}$.

3. If the hypergraph H with m_i edges of order i for $i = 1, \ldots, n$ is an antichain, then $\sum\limits_{i=0}^{n} m_i \binom{n}{i}^{-1} \leq 1$.

4. The complete hypergraph K_n^* can be partitioned into symmetric chains.

5. *Kleitman's lemma*: Let D and U be hypergraphs on the same n vertices. Let D be a d-edge downset and U a u-edge upset. And let D and U have m common edges. Then $du \geq 2^n m$.

6. An n-vertex hypergraph clique has at most 2^{n-1} edges.

7. An r-uniform n-vertex hypergraph clique n has at most $\binom{n-1}{r-1}$ edges if $n \geq 2r$.

8. In any r-uniform hypergraph H, the maximum size r-partite partial hypergraph contains at least $\frac{r!}{r^r}$ of the edges of H.

9. Let H be an n-vertex, m-edge hypergraph clique, such that each pair of distinct edges intersect in exactly one vertex. Then $m \leq n$. (de Bruijn and Erdős)

10. *Fisher's inequality*: Let H be an n-vertex, m-edge hypergraph clique such that each pair of edges intersects in λ vertices. Then $m \leq n$.

11. *Modular intersection theorem*: Let L be a set of s integers, and let p be a prime number. Let H be an r-uniform hypergraph such that $r \notin L \mod p$ and that the intersection size for each pair of distinct edges is in $L \mod p$. Then $m \leq \binom{n}{s}$.

Examples:

1. The Fano plane (see §12.1.1) is the hypergraph with (using mod 7 arithmetic):

$$V = \{1, 2, \ldots, 7\} \text{ and } E = \{\,\{1+i, 2+i, 4+i\} \mid 1 \le i \le 7\,\}.$$

2. A block design is a regular, uniform hypergraph such that each pair of vertices is contained in precisely λ edges. Block designs often provide extremal examples in problems of hypergraph theory.

3. A matroid (see §12.4.1) can be regarded as a hypergraph such that under every nonnegative weighting of the vertices, a greedy algorithm would find an edge of maximum weight.

8.12.3 NUMERICAL INVARIANTS OF HYPERGRAPHS

Calculating formulas for the values of some standard numerical invariants of hypergraphs tends to be quite difficult, even for complete hypergraphs. Two famous examples are Lovász's proof of the Kneser conjecture and Baranyai's proof of the factorization theorem.

Definitions:

The ***maxdegree*** $\Delta(H)$ is the largest degree of any vertex in the hypergraph H.

The ***chromatic number*** $\chi(H)$ is the smallest number of independent sets required to partition the vertex set of H. To ensure the existence of such partitions it is assumed that H does not contain any edges with just one vertex.

The ***independence number*** $\alpha(H)$ is the maximum number of vertices which form an independent set in H.

The ***chromatic index*** $q(H)$ is the smallest number of matchings required to partition the edges of H.

A hypergraph H is ***normal*** if $q(H) = \Delta(H)$.

The ***transversal number*** $\tau(H)$ is the minimum cardinality (i.e., number of vertices), taken over all transversals of H.

The ***matching number*** $\nu(H)$ is the maximum number of pairwise disjoint edges of H, i.e., the cardinality of the largest partial of H which forms a matching.

The ***clique partition number*** $cp(H)$ is the smallest number of cliques required to partition the edge set of H.

The ***clique number*** $\omega(H)$ is the largest number of edges of any partial clique in the hypergraph H.

Facts:

1. Many hypergraph invariants are representable as graph invariants. In particular,

$$\omega(H) = \omega(I(H)), \quad \nu(H) = \alpha(I(H)), \quad q(H) = \chi(I(H)), \quad cp(H) = \chi(\overline{I(H)})$$

where $\overline{G}$ denotes the edge-complement of a graph G.

2. Every hypergraph H satisfies the following two *min* $\geq$ *max* relations:

$$q(H) \ge cp(H) \ge \Delta(H), \qquad \tau(H) \ge cp(H) \ge \nu(H).$$

3. A hypergraph H is normal if and only if $\tau(H') = \nu(H')$ for all partials H' of H. (Lovász, 1972)

4. The following relations hold in every n-vertex hypergraph H:

$$\tau(H) = n - \alpha(H), \qquad \chi(H) \geq \frac{n}{\alpha(H)}, \qquad \chi(H) + \alpha(H) \leq n + 1.$$

5. The parameters $\chi(H)$ and $\tau(H)$ can be approximated by greedy algorithms.

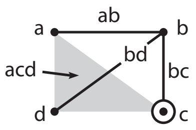
6. The *Kneser conjecture* that $cp(K^r_{2r+k}) = k + 2$ was proved by topological methods. (Lovász and Bárány, 1978)

7. The *factorization theorem* that $q(K^r_{kr}) = \binom{kr-1}{r-1}$ was proved by using network flows. (Baranyai, 1975)

8. Hypergraphs in the following classes are known to be bicolorable (i.e., $\chi(H) = 2$): normal hypergraphs (including unimodular hypergraphs), r-uniform hypergraphs with size at most 2^{r-1}, r-uniform hypergraphs in which each edge intersects at most 2^{r-3} other edges (proved by probabilistic methods), finite planes of order at least three.

Examples:

1. Consider the hypergraph H of §8.12.1, Example 1 with $V = \{a, b, c, d\}$ and $E = \{ab, bc, bd, acd, c\}$. The maximum degree $\Delta(H)$ is 3, since vertex c has degree 3. The chromatic number $\chi(H)$ is 4, since every pair of vertices lies in some edge, so all four vertices must get different colors. The independence number $\alpha(H)$ is 1, since every pair of vertices lies in some edge. The chromatic index $q(H)$ is 4, using the matching c, ab.



The hypergraph H is not normal, since $q(H) = 4$, but $\Delta(H) = 3$. The transversal number $\tau(H)$ is 2, using the transversal b, c. The matching number $\nu(H)$ is 2, using the matching ab, c.

2. The Fano plane (§8.12.2, Example 1) has the following parameters: $\omega = q = 7$, $\Delta = \tau = \chi = 3$, $\alpha = 4$, $\nu = cp = 1$.

TREES

INTRODUCTION

A tree is a connected graph containing no cycles. Trees have applications in a wide variety of disciplines, particularly computer science. For example, they can be used to construct searching algorithms for finding a particular item in a list, to store data, to model decisions and their outcomes, or to design networks.

GLOSSARY

ancestor (of a vertex v in a rooted tree): any vertex on a path to v from the root.

m-ary tree: a rooted tree in which every internal vertex has at most m children.

backtrack: a pair of successive edges in a walk where the second edge is the same as the first, but traversed in the opposite direction.

balanced tree: a rooted m-ary tree of height h such that all leaves of the tree have height h or $h{-}1$.

bihomogeneous tree: a tree (usually infinite) in which there are exactly two values for the vertex degrees.

binary search tree (BST): a type of binary tree used to represent a table of data, which is efficiently accessed by storage and retrieval algorithms.

binary tree: an ordered rooted tree in which each vertex has at most two children, that is, a possible "left child" and a possible "right child"; an only child must be designated either as a left child or a right child (this usage is standard for computer science); an m-ary tree in which $m = 2$ (in pure graph theory).

bounded tree: a (possibly infinite) tree of finite diameter.

breadth-first search: a method for visiting all the vertices of a graph in a sequence, in order of their proximity to a designated starting vertex.

caterpillar: a tree that contains a path such that every edge has one or both endpoints in that path.

center (of a tree): the set of vertices of minimum eccentricity.

child (of a vertex v in a rooted tree): a vertex such that v is its immediate ancestor.

chord: for a graph G with a spanning tree T, an edge e of G such that $e \notin T$.

complete binary tree: a binary tree where every parent has two children and all leaves are at the same depth.

decision tree: a rooted tree in which every internal vertex represents a decision and each path from the root to a leaf represents a sequence of decisions.

depth (of a vertex in a rooted tree): the number of edges in the unique path from the root to that vertex.

depth-first search: a method for visiting every vertex of a graph by progressing as far as possible from the most recently visited vertex, before doing any backtracking.

descendant (of a vertex v in a rooted tree): a vertex that follows v on a path away from the root.

diameter (of a tree): the maximum distance between two vertices in the tree.

distance (between two vertices in a tree): the number of edges in the unique (simple) path between these vertices.

eccentricity (of a vertex in a tree): the length of the longest simple path beginning at that vertex.

finite tree: a tree with a finite number of vertices and edges.

forest: a graph with no cycles.

full m-ary tree: a rooted tree in which every internal vertex has exactly m children.

fundamental cycle: in a connected graph G, the unique cycle created by adding the edge $e \in E_G$ not in T to a spanning tree T.

fundamental edge-cut: in a connected graph G, the partition-cut $\langle X_1, X_2\rangle$ where X_1 and X_2 are the vertex sets of the two components of $T - e$ for some edge e in a spanning tree T for G.

fundamental system of cycles: in a connected graph G, the set of fundamental cycles corresponding to the various edges of $G - T$, where T is a spanning tree for G.

fundamental system of edge-cuts: in a connected graph G, the set of fundamental edge-cuts that result from removal of an edge from a spanning tree T for G.

height (of a rooted tree): the maximum of the levels of its vertices.

homogeneous: property of an (infinite) tree that every vertex has the same degree.

n-homogeneous: property of an (infinite) tree that every vertex has degree n.

infinite tree: a tree with an infinite number of vertices and edges.

inorder traversal (of an ordered rooted tree): a recursive listing of all vertices starting with the vertices of the first subtree of the root, next the root vertex itself, and then the vertices of the other subtrees as they occur from left to right.

internal vertex (of a rooted tree): a vertex with children.

isomorphism (of trees): for trees X and Y, a pair of bijections $f_V \colon V_X \to V_Y$ and $f_E \colon E_X \to E_Y$ such that if u and v are the endpoints of an edge e in the tree X, then $f_V(u)$ and $f_V(v)$ are the endpoints of the edge $f_E(e)$ in the tree Y (see §8.1).

isomorphism (of rooted trees): for rooted trees (T_1, r_1) and (T_2, r_2), a tree isomorphism $f \colon T_1 \to T_2$ that takes r_1 to r_2.

labeled tree: a tree with labels such as $v_1, v_2, \ldots, v_n$ assigned to its vertices.

leaf: in a rooted tree, a vertex that has no children.

left child (of a vertex in an ordered, rooted binary tree): the first child of that vertex.

left-right tree: Synonym for *full binary tree.*

left subtree (of an ordered, rooted binary tree): the subtree rooted at a left child.

level (of a vertex in a rooted tree): the length of the unique path from the root to this vertex.

locally finite tree: a tree in which the degree of every vertex is finite.

nth level (of a rooted tree): the set of all vertices at depth n.

ordered tree: a rooted tree in which the children of each internal vertex are linearly ordered.

parent (of a vertex v, other than the root, in a rooted tree): a vertex that is the immediate predecessor of v on the unique path away from the root to v.

partition-cut of a graph: given a partition of the set of vertices of G into X_1 and X_2, the set $\langle X_1, X_2 \rangle$ of edges of G that have one endpoint in X_1 and the other in X_2.

postorder traversal (of an ordered rooted tree): a recursive listing of vertices starting with the vertices of subtrees as they occur from left to right, followed by the root.

preorder traversal (of an ordered rooted tree): a recursive listing of vertices starting with the root, then the vertices of the first subtree, followed by the vertices of other subtrees as they occur from left to right.

reduced tree: a tree with no vertices of degree 2.

reduced walk: a walk in a graph without backtracking.

regular: Synonym for *homogeneous*.

right child (of a vertex in an ordered rooted binary tree): the second child of that vertex.

right subtree (of an ordered, rooted binary tree): the subtree rooted at the right child.

rooted tree: a tree in which one vertex is designated as the "root".

siblings (in a rooted tree): vertices with the same parent.

spanning tree (of a connected graph): a subgraph that is a tree and contains all the vertices of the graph.

subtree: a subgraph of a tree that is also a tree.

tree: a connected graph with no cycles.

tree edge: for a graph G with a spanning tree T, an edge e of G such that $e \in T$.

tree traversal: a walk that visits all the vertices of a tree.

9.1 CHARACTERIZATIONS AND TYPES OF TREES

9.1.1 PROPERTIES OF TREES

For trees, as with other graphs, there is a wide variety of terminology in use from one application or specialty to another.

Definitions:

A graph is ***acyclic*** if it contains no subgraph isomorphic to a cycle C_n (see §8.1.3).

A ***forest*** is an acyclic graph.

A ***tree*** is an acyclic connected graph. (*Note*: Unless stated otherwise, all trees are assumed to be finite, i.e., to have a finite number of vertices.)

A ***walk*** is an alternating sequence $v_0, e_1, v_1, \ldots, e_r, v_r$ of vertices and edges in which each edge e_i joins vertices v_{i-1} and v_i.

A ***path*** (sometimes called a ***simple path***) is a walk where all the vertices are different.

The ***eccentricity*** of a vertex is the length of the longest (simple) path beginning at that vertex.

The ***center*** of a tree contains all vertices with minimum eccentricity.

An ***end vertex*** of a tree is a vertex of degree 1.

A ***caterpillar*** is a tree that contains a path such that every edge has one or both endpoints in that path.

Facts:

1. A (finite) tree with at least two vertices has at least two end vertices.

2. A connected graph with n vertices is a tree if and only if has exactly $n - 1$ edges.

3. A graph is a tree if and only if there is a unique (simple) path between any two vertices.

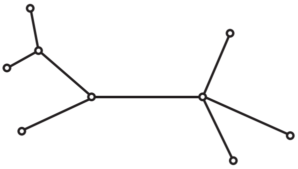
4. A graph is a forest if and only if every edge is a cut-edge. (See §8.4.2.)

5. Trees are bipartite. Hence, every tree can be colored using two colors.

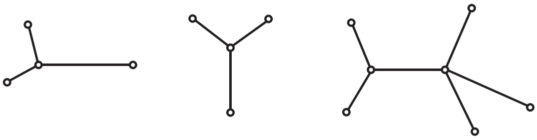
6. The center of a tree consists of either only one vertex or two adjacent vertices.

Examples:

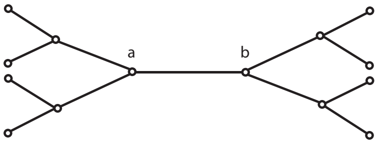
1. The following tree has 9 vertices and $9 - 1 = 8$ edges.



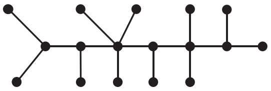
2. The following graph is a forest with three components.



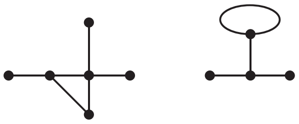
3. The center of the following tree consists of the two adjacent vertices a and b.



4. The following tree is a caterpillar.



5. Neither of the following graphs is a tree. One contains a 3-cycle, and the other contains a 1-cycle (i.e., a self-loop).



9.1.2 ROOTS AND ORDERINGS

Adding some extra structure to trees adapts them to applications in many disciplines, especially computer science.

Definitions:

A ***rooted tree*** (T, r) is a tree T with a distinguished vertex r (the ***root***), in which all edges are implicitly directed away from the root.

Two rooted trees (T_1, r_1) and (T_2, r_2) are ***isomorphic as rooted trees*** if there is an isomorphism $f\colon T_1 \to T_2$ (see §8.1.2) that takes r_1 to r_2.

A ***child*** of a vertex v in a rooted tree is a vertex that is the immediate successor of v on a path away from the root.

A ***descendant*** of a vertex v in a rooted tree is v itself or any vertex that is a successor of v on a path away from the root. A ***proper descendant*** of a vertex v in a rooted tree is any descendant except v itself.

The ***parent*** of a vertex v in a rooted tree is a vertex that is the immediate predecessor of v on the path to v away from the root.

The ***parent function*** of a rooted tree T maps the root of T to the empty set and maps every other vertex to its parent.

An ***ancestor*** of a vertex v in a rooted tree is v itself or any vertex on the path to v away from the root. A ***proper ancestor*** of a vertex v in a rooted tree is any ancestor except v itself.

Siblings in a rooted tree are vertices with the same parent.

An ***internal vertex*** in a rooted tree is a vertex with children.

A ***leaf*** in a rooted tree is a vertex that has no children.

The ***depth*** of a vertex in a rooted tree is the number of edges in the unique path from the root to that vertex.

The ***nth level*** in a rooted tree is the set of all vertices at depth n.

The ***height*** of a rooted tree is the maximum depth over all vertices.

An ***ordered tree*** is a rooted tree in which the children of each internal vertex are linearly ordered.

A ***left sibling*** of a vertex v in an ordered tree is a sibling that precedes v in the ordering of v and its siblings. A ***right sibling*** of a vertex v in an ordered tree is a sibling that follows v in the ordering of v and its siblings.

A ***plane tree*** is a geometric realization (drawing) of an ordered tree such that the left-to-right order of the children of each vertex in the drawing is consistent with the linear ordering of the corresponding vertices in the tree.

In the ***level ordering*** of the vertices of an ordered tree, u precedes v under any of these circumstances:

- if the depth of u is less than the depth of v;
- if u is a left sibling of v;
- if the parent of u precedes the parent of v.

Two ordered trees (T_1, r_1) and (T_2, r_2) are ***isomorphic as ordered trees*** if there is a rooted tree isomorphism $f\colon T_1 \to T_2$ that preserves the ordering at every vertex.

An ***m-ary tree*** is a rooted tree such that every internal vertex has at most m children.

A ***full m-ary tree*** is a rooted tree such that every internal vertex has exactly m children.

A (***pure***) ***binary tree*** is a rooted tree such that every internal vertex has at most two children. This meaning of "binary tree" occurs commonly in graph theory.

A ***binary tree*** is a 2-ary tree such that every child, even an only child, is distinguished as ***left child*** or ***right child***. This meaning of "binary tree" occurs commonly in computer science and in permutation groups.

The ***principal subtree*** at a vertex v of a rooted tree comprises all descendants of v and all edges incident to these descendants. It is itself a rooted tree with v designated as its root.

The ***left subtree*** of a vertex v in a binary tree is the principal subtree at the left child. The ***right subtree*** of v is the principal subtree at the right child.

A ***balanced tree*** of height h is a rooted m-ary tree in which all leaves are of height h or $h-1$.

A ***complete binary tree*** is a binary tree in which every parent has two children and all leaves are at the same depth.

A ***complete m-ary tree*** is an m-ary tree in which every parent has m children and all leaves are at the same depth.

A ***decision tree*** is a rooted tree in which every internal vertex represents a decision and each path from the root to a leaf represents a sequence of decisions.

A ***prefix code*** for a finite set $X = \{x_1, \ldots, x_n\}$ is a set $\{c_1, \ldots, c_n\}$ of binary strings in X (called *codewords*) such that no codeword is a prefix of any other codeword.

A ***Huffman code*** for a set X with a probability measure Pr (see §7.1) is a prefix code $\{c_1, \ldots, c_n\}$ such that $\sum_{j=1}^{n} len(c_j) Pr(x_j)$ is minimum among all prefix codes, where $len(c_j)$ measures the length of c_j in bits.

A ***Huffman tree*** for a set X with a probability measure Pr is a tree constructed by Huffman's algorithm to produce a Huffman code for (X, Pr).

Facts:

1. Plane trees are usually drawn so that vertices of the same level in the corresponding ordered tree are at the same vertical position in the plane.

2. A rooted tree can be represented by its vertex set plus its parent function.

3. The concept of finite binary tree also has the following recursive definition: (basis) an ordered tree with only one vertex is a binary tree; (recursion) an ordered tree with more than one vertex is a binary tree if the root has at most two children and if both its principal subtrees are binary trees.

4. A full m-ary tree with k internal vertices has $mk+1$ vertices and $(m-1)k+1$ leaves.

5. A full m-ary tree with k vertices has $(k-1)/m$ internal vertices and $((m-1)k+1)/m$ leaves.

6. There are at most m^h leaves in any m-ary tree of height h.

7. A *binary search tree* is a special kind of binary tree used to implement a *random access table* with $O(n)$ maintenance and retrieval algorithms. (See §18.2.3.)

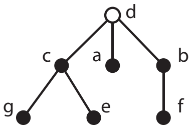
8. A balanced binary tree can be used to implement a *priority queue* with $O(n)$ enqueue and dequeue algorithms. (See §18.2.4.)

9. Algorithm 1, due to D. Huffman in 1951, constructs a Huffman tree.

```
Algorithm 1: Find a Huffman code.
  input: the probabilities $Pr(x_1), \ldots, Pr(x_n)$ on a set $X$
  output: a Huffman code for $(X, Pr)$
  initialize $F$ to be a forest of isolated vertices, labeled $x_1, \ldots, x_n$, each to be
        regarded as a rooted tree
  assign weight $Pr(x_j)$ to the rooted tree $x_j$, for $j = 1, \ldots, n$
  repeat until forest $F$ is a single tree
    choose two rooted trees, $T$ and $T'$, of smallest weights in forest $F$
    replace trees $T$ and $T'$ in forest $F$ by a tree with a new root whose left subtree
        is $T$ and whose right subtree is $T'$
    label the new edge to $T$ with a 0 and the new edge to $T'$ with a 1
    assign weight $w(T) + w(T')$ to the new tree
  return tree $F$
  {The Huffman code word for $x_i$ is the concatenation of the labels on the unique
      path from the root to $x_i$}
```

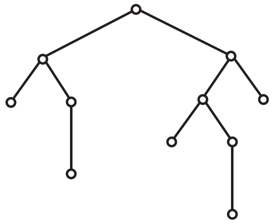
Examples:

1. The following is a rooted tree (T, d) with root d.

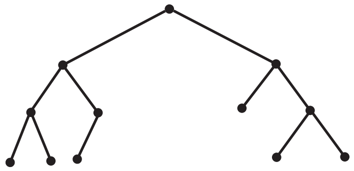


vertex	a	b	c	d	e	f	g
parent	d	d	d	$\emptyset$	c	b	c

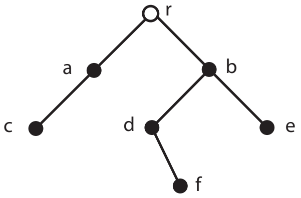
2. The following is a 2-ary tree of height 4.



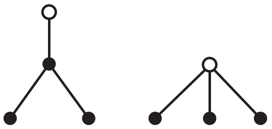
3. A balanced binary tree is shown next.



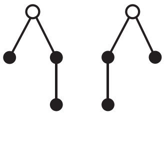
4. The following tree is rooted at vertex r. Vertices d and e are children of vertex b. Vertex f is a descendant of f, d, b, and r, but f is not a descendant of vertex a. Vertex a is the parent of c, which is the only proper descendant of vertex a. Vertices d and e are siblings, but c is not a sibling of d or of e. The leaves are c, e, f; the internal vertices are a, b, r, d.



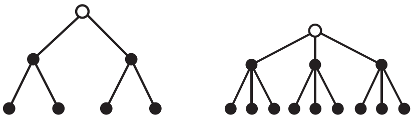
5. The following two rooted trees are isomorphic as graphs, but they are considered to be different as rooted trees, because there is no graph isomorphism from one to the other that maps root to root.



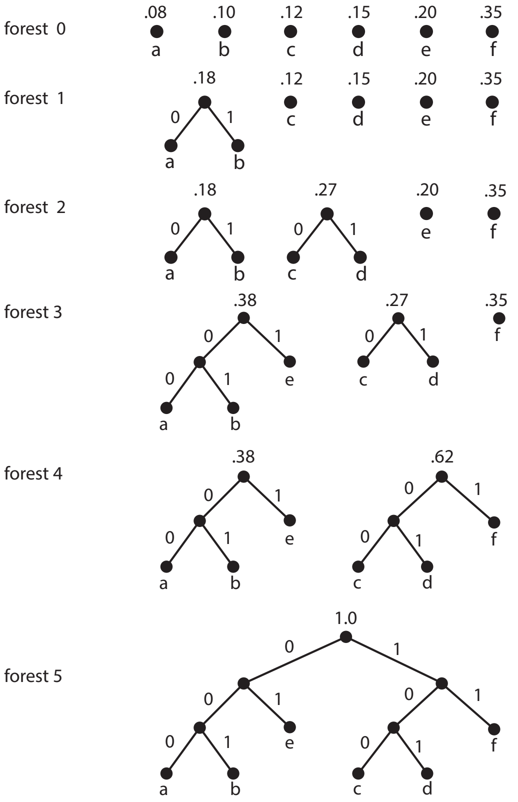
6. The following two plane trees are isomorphic as rooted trees, but they are not isomorphic as ordered rooted trees, because there is no rooted tree isomorphism from one to the other that preserves the child ordering at every vertex.



7. A complete binary tree of height 2 and a complete 3-ary tree of height 2 are shown next.



8. The iterative construction of a *Huffman tree* for the set $X = \{a, b, c, d, e, f\}$ with respective probabilities $\{0.08, 0.10, 0.12, 0.15, 0.20, 0.35\}$ would proceed as follows:



The resulting codes are 000 for a, 001 for b, 100 for c, 101 for d, 01 for e, and 11 for f. So the most frequently used objects in X are represented by the shortest codes.

9.1.3 TREE TRAVERSAL

Ordered rooted trees can be used to store data or arithmetic expressions involving numbers, variables, and operations. A tree traversal algorithm gives a systematic method for accessing the information stored in the tree.

Definitions:

A ***boundary walk*** of a plane tree is a walk around the boundary of the single region of the plane imbedding of the tree, starting at the root.

A ***backtrack*** along a walk in a graph is an instance $\ldots, u, e, v, e, u, \ldots$ of two consecutive edge-steps in which an edge-step traverses the same edge as its predecessor, but in the opposite direction.

A ***preorder traversal*** of an ordered rooted tree T lists the vertices of T (or their labels) so that each vertex v is followed by all the vertices, in preorder, in its principal subtrees, respecting their left-to-right order.

A ***postorder traversal*** of an ordered rooted tree T lists the vertices of T (or their labels) so that each vertex v is preceded by all the vertices, in postorder, in its principal subtrees, respecting their left-to-right order.

An ***inorder traversal*** of an ordered rooted tree T lists the vertices of T (or their labels) so that each vertex v is preceded by all the vertices, in inorder, in its first principal subtree and so that v is followed by the vertices, in inorder, of its other principal subtrees, respecting their left-to-right order.

Prefix (***or Polish***) ***notation*** is the form of an arithmetic expression obtained from a preorder traversal of a binary tree representing this expression.

Postfix (***or reverse Polish***) ***notation*** is the form of an arithmetic expression obtained from a postorder traversal of a binary tree representing this expression.

Infix notation is the form of an arithmetic expression obtained from an inorder traversal of a binary tree representing this expression. A left parenthesis is written immediately before writing the left principal subtree of each vertex, and a right parenthesis is written immediately after writing the right principal subtree.

The ***universal address system*** of an ordered rooted tree is a labeling in which the root is labeled 0 and for each vertex with label x, its m children are labeled $x.1, x.2, \ldots, x.m$, from left to right.

In the ***level order*** of the vertices of an ordered tree T, vertex u precedes vertex v if u is nearer the root, or if u and v are at the same level and u and v have ancestors u' and v' that are siblings and u' precedes v' in the ordering of T.

A bijective assignment of labels from an ordered set (such as alphabetic strings or the integers) to the vertices of an ordered tree is ***sorted*** if the level order of these labels is either ascending or descending.

Facts:

1. The preorder traversal of a plane tree is obtained by a counterclockwise traversal of the boundary walk of the plane region, that is, starting downward toward the left. As each vertex of the tree is encountered for the first time along this walk, it is recorded in the preorder.

2. The postorder traversal of a plane tree is obtained by a counterclockwise traversal of the boundary walk of the plane region, that is, starting downward toward the left. As each vertex of the tree is encountered for the last time along this walk, it is recorded in the postorder. Algorithm 2 uses this to find the parents of all vertices.

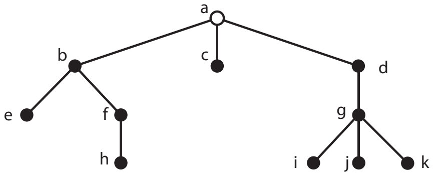
3. The inorder traversal of a plane tree is obtained by a counterclockwise traversal of the boundary walk of the plane region, that is, starting downward toward the left. As each interior vertex of the tree is encountered for the second time along this walk, it is recorded in the inorder. An end vertex is recorded whenever it is encountered for the only time.

4. Two nonisomorphic ordered trees with sorted vertex labels can have the same preorder but not the same postorder.

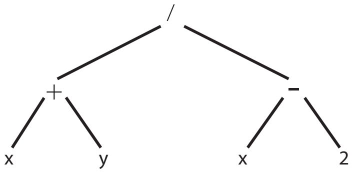
```
Algorithm 2: Parent-finder for the postorder of a plane tree.
  input: the postorder $v_{p(1)}, \ldots, v_{p(n)}$ of a plane tree with sorted vertex labels and
         a vertex $v_j$
  output: the parent of $v_j$
  scan the postorder until $v_j$ is encountered
  continue scanning until some vertex $v_i$ is encountered such that $i < j$
  return $(v_i)$
```

Examples:

1. The following plane tree has preorder $a\,b\,e\,f\,h\,c\,d\,g\,i\,j\,k$, postorder $e\,h\,f\,b\,c\,i\,j\,k\,g\,d\,a$, and inorder $e\,b\,h\,f\,a\,c\,i\,g\,j\,k\,d$.



2. The following binary tree represents the arithmetic expression that has infix form $(x+y)/(x-2)$, prefix form $/ + x\ y - x\ 2$, and postfix form $x\ y + x\ 2 -\ /$.



9.1.4 INFINITE TREES

Definitions:

An ***infinite tree*** is a tree with an infinite number of vertices and edges.

The ***diameter*** of a tree is the maximum distance between two distinct vertices in the tree.

A ***bounded tree*** is a tree of finite diameter.

The ***degree*** of a vertex is the number of edges incident with it.

A ***locally finite tree*** is a tree in which the degree of every vertex is finite.

A ***homogeneous tree*** is a tree in which every vertex has the same degree.

An ***n-homogeneous tree*** is a tree in which every vertex has degree n.

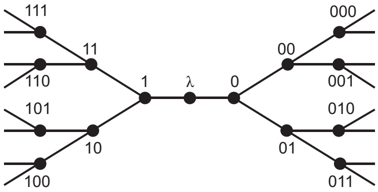
A ***bihomogeneous tree*** is a nonhomogeneous tree with a partition of the vertices into two subsets, such that all vertices in the same subset have the same degree.

Facts:

1. *König's lemma:* An infinite tree that is locally finite contains an infinitely long path.

Examples:

1. Suppose that two finite bitstrings are considered adjacent if one bitstring can be obtained from the other by appending a 0 or a 1 at the right. The resulting graph is the infinite bihomogeneous tree, in which the empty string λ has degree 2 and all other finite bitstrings have degree 3.



2. Consider the set of all finite strings on the alphabet $\{a, a^{-1}, b, b^{-1}\}$ containing no instances of the substrings aa^{-1}, $a^{-1}a$, bb^{-1}, or $b^{-1}b$. Suppose that two such strings are considered to be adjacent if and only if one of them can be obtained from the other by appending one of the alphabet symbols at the right. Then the resulting graph is a 4-homogeneous tree.

3. Consider as vertices the set of infinite bitstrings with at most two 1s. Suppose two such bitstrings are regarded as adjacent if they differ in only one bit and that bit is a rightmost 1 for one of the two bitstrings. This graph is a bounded tree of diameter four.

9.2 SPANNING TREES

A spanning tree of a graph G is a subgraph of G that is a tree and contains every vertex of G. Spanning trees are very useful in searching the vertices of a graph and in communicating from any given vertex to the other vertices. Minimum spanning trees are covered in §10.1.

9.2.1 DEPTH-FIRST AND BREADTH-FIRST SPANNING TREES

Definitions:

A ***spanning tree*** of a graph G is a tree that is a subgraph of G and that contains every vertex of G.

A ***tree edge*** of a graph G with a spanning tree T is an edge e such that $e \in T$.

A ***chord*** of a graph G with a spanning tree T is an edge e such that $e \notin T$.

A ***back edge*** of a digraph G with a spanning tree T is a chord that joins one of its endpoints to an ancestor in T. A ***forward edge*** is a chord that joins one of its endpoints to a descendant in T. A ***cross edge*** is a chord that is neither a back edge nor a forward edge.

The ***fundamental cycle*** of a chord e with respect to a given spanning tree T of a graph G consists of the edge e and the unique path in T joining the endpoints of e.

A ***depth-first search*** (***DFS***) of a graph G is a way to traverse every vertex of a connected graph by constructing a spanning tree, rooted at a given vertex r. Each stage of the DFS traversal seeks to move to an unvisited neighbor of the most recently visited vertex, and backtracks only if there is none available. See Algorithm 1.

A ***depth-first search tree*** is the spanning tree constructed during a depth-first search.

Backtracking during a depth-first search means retreating from a vertex with no unvisited neighbors back to its parent in the DFS-tree.

A ***breadth-first search*** (***BFS***) of a graph G is a way to traverse every vertex of a connected graph by constructing a spanning tree, rooted at a given vertex r. After the BFS traversal visits a vertex v, all of the previously unvisited neighbors of v are enqueued, and then the traversal removes from the queue whatever vertex is at the front of the queue, and visits that vertex. See Algorithm 2.

A ***breadth-first search tree*** is the spanning tree constructed during a breadth-first search.

The ***fundamental system of cycles*** of a connected graph G associated with a spanning tree T is the set of fundamental cycles corresponding to the various edges of $G - T$.

Given two vertex sets X_1 and X_2 that partition the vertex set of a graph G, the ***partition-cut*** $\langle X_1, X_2\rangle$ is the set of edges of G that have one endpoint in X_1 and the other in X_2.

The ***fundamental edge-cut*** of a connected graph G associated with removal of an edge e from a spanning tree T is the partition-cut $\langle X_1, X_2\rangle$ where X_1 and X_2 are the vertex sets of the two components of $T - e$.

The ***fundamental system of edge-cuts*** of a connected graph G associated with a spanning tree T is the set of fundamental edge-cuts that result from removal of an edge from the tree T.

```
Algorithm 1:  Depth-first search spanning tree.
  input: a connected $n$-vertex graph $G$ and a starting vertex $r$
  output: the edge set $E_T$ of a spanning tree and an array $X[1..n]$ listing $V_G$ in
     DFS order

  initialize all vertices as unvisited and all edges as unused
  $E_T := \emptyset$; $loc := 1$
  $dfs(r)$

  procedure $dfs(u)$
  mark $u$ as visited
  $X[loc] := u$
  $loc := loc + 1$
  while vertex $u$ has any unused edges
     $e :=$ next unused edge at $u$
```

```
    mark $e$ as *used*
    $w$ := the other endpoint of edge $e$
    **if** $w$ is *unvisited* **then**
      add $e$ to $E_T$
      $dfs(w)$
```

Algorithm 2: **Breadth-first search spanning tree.**

```
input: a connected $n$-vertex graph $G$ and a starting vertex $r$.
output: the edge set $E_T$ of a spanning tree and an array $X[1..n]$ listing $V_G$ in
  BFS order

initialize all vertices as *unvisited* and all edges as *unused*
$E_T := \emptyset$; $loc := 1$; $Q := r$  {$Q$ is a queue}
**while** $Q \neq \emptyset$
  $x := front(Q)$
  remove $x$ from $Q$
  $bfs(x)$

**procedure** $bfs(u)$
mark $u$ as *visited*
$X[loc] := u$
$loc := loc + 1$
**while** vertex $u$ has any *unused* edges
  $e$ := next *unused* edge at $u$
  mark $e$ as *used*
  $w$ := the other endpoint of edge $e$
  **if** $w$ is *unvisited* **then**
    add $e$ to $E_T$
    add $w$ to the back of $Q$
```

Facts:

1. Every connected graph has at least one spanning tree.

2. A connected graph G has k edge-disjoint spanning trees if and only if for every partition of V_G into m nonempty subsets, there are at least $k(m-1)$ edges connecting vertices in different subsets.

3. Let T and T' be spanning trees of a graph G and $e \in T - T'$. Then there exists an edge $e' \in T' - T$ such that both $T - e \cup \{e'\}$ and $T' - e' \cup \{e\}$ are spanning trees of G.

4. In the column vector space of the incidence matrix of G over Z_2, every edge set can be represented as a sum of column vectors. Let T be a spanning tree of G. Then each cycle C can be written in a unique way as a linear combination of the fundamental cycles of whatever chords of T occur in C.

5. Depth-first search on an n-vertex, m-edge graph runs in $O(m)$ time.

6. DFS-trees are used to find the components, cutpoints, blocks, and cut-edges of a graph.

7. The unique path in the BFS-tree T of a graph G from its root r to a vertex v is a shortest path in G from r to v.

8. Breadth-first search on an n-vertex, m-edge graph runs in $O(m)$ time.

9. A BFS-tree in a simple graph has no back edges.

10. Dijkstra's algorithm (see §10.3.2) constructs a spanning tree T in an edge-weighted graph such that for each vertex v, the unique path in T from a specified root r to v is a minimum-cost path in the graph from r to v. When all edges have unit weights, Dijkstra's algorithm produces the BFS tree.

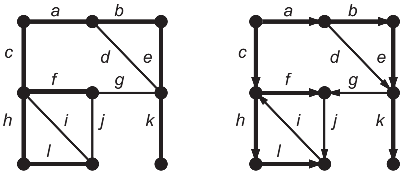
11. The level order of the vertices of an ordered tree is the order in which they would be traversed in a breadth-first search of the tree.

12. The fundamental cycle of an edge e with respect to a spanning tree T such that $e \notin T$ consists of edge e and those edges of T whose fundamental edge-cuts contain e.

13. The fundamental edge-cut with respect to removal of edge e from a spanning tree T consists of edge e and those edges of $E_G - E_T$ whose fundamental cycles contain e.

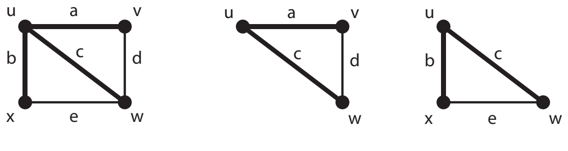
Examples:

1. Consider the following graph and spanning tree and a digraph on the same vertex and edge set. The tree edges are a, b, c, e, f, h, k, l, and the chords are d, g, i, j. Chord d is a forward edge, chord i is a back edge, and chords g and j are cross edges.

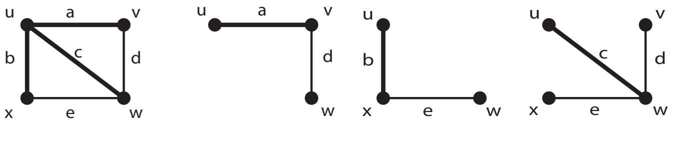


2. In the graph of Example 1, the fundamental cycles of the chords d, g, i, and j are $\{d, b, e\}$, $\{g, f, c, a, b, e\}$, $\{i, h, l\}$, and $\{j, f, h, l\}$, respectively. The non-fundamental cycle $\{a, d, g, c, f\}$ is the sum (mod 2) of the fundamental cycles of chords d and g.

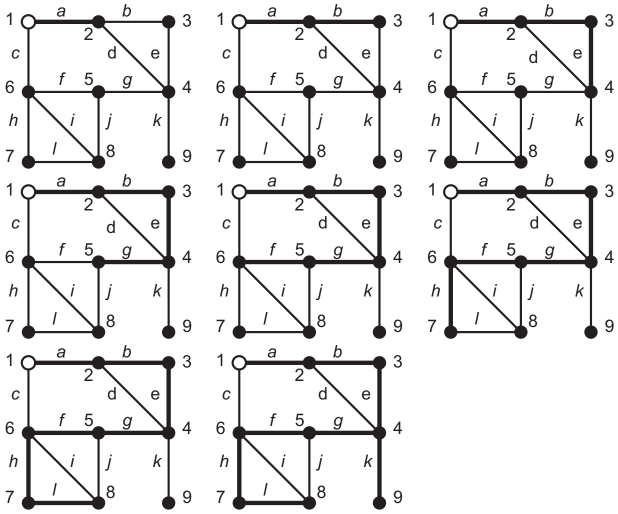
3. A spanning tree and its fundamental system of cycles are shown next.



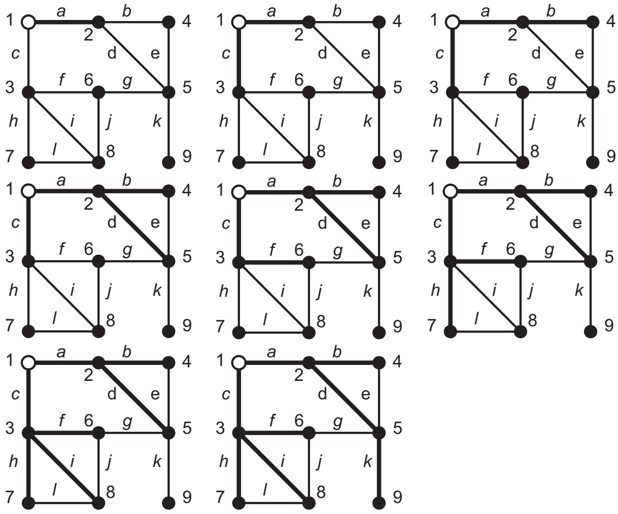
4. A spanning tree and its fundamental system of edge-cuts are shown next.



5. In the graph of Example 1 suppose that the local order of adjacencies at each vertex is the alphabetic order of the edge labels. Then the construction of the DFS-tree is shown in the following figure.



6. In the graph of Example 1 suppose that the local order of adjacencies at each vertex is the alphabetic order of the edge labels. Then the construction of the BFS-tree is shown in the following figure.



9.2.2 ENUMERATION OF SPANNING TREES

Definitions:

The ***number of spanning trees*** $\tau(G)$ of a graph G counts two spanning trees T_1 and T_2 as different if their edge sets are different, even if there is an automorphism of G mapping T_1 onto T_2.

The ***degree matrix*** $D(G)$ of an n-vertex graph G with vertex degree sequence $d_1, \ldots, d_n$ is the $n \times n$ diagonal matrix in which the elements of the main diagonal are the degrees $d_1, \ldots, d_n$ (and the off-diagonal elements are 0s).

Facts:

1. *Cayley's formula*: $\tau(K_n) = n^{n-2}$, where K_n is the complete graph.

2. $\tau(K_{m,n}) = m^{n-1}n^{m-1}$, where $K_{m,n}$ is the complete bipartite graph.

3. $\tau(I_s * K_{n-s}) = n^{n-2}\left(1 - s/n)\right)^{s-1}$, where I_s is the edgeless graph on n vertices and "$*$" denotes the join (see §8.1.2).

4. $\tau(W_n) = \left(\frac{3+\sqrt{5}}{2}\right)^n + \left(\frac{3-\sqrt{5}}{2}\right)^n - 2$, where W_n denotes the wheel with n rim vertices.

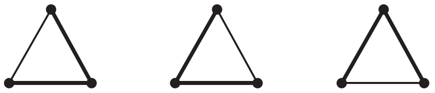
5. *Matrix-tree theorem*: For each s and t, the value $\tau(G)$ equals $(-1)^{s+t}$ times the determinant of the matrix obtained by deleting row s and column t from $D(G) - A(G)$, where $A(G)$ is the adjacency matrix for G.

6. For each edge e of a graph G, $\tau(G) = \tau(G - e) + \tau(G/e)$, where "$-e$" denotes edge deletion and "$/e$" denotes edge contraction.

7. The number of spanning trees of K_n with degrees $d_1, \ldots, d_n$ equals $\binom{n-2}{d_1-1,\ldots,d_n-1}$ (see §2.3.2). In this formula, the vertices are distinguishable (labeled) and are given their degrees in advance, and the only question is how to realize them with edges.

Examples:

1. $\tau(K_3) = 3^{3-2} = 3$. Each of the three spanning trees is a path on two edges, as illustrated below. Also, $\tau(K_4) = 4^{4-2} = 16$.

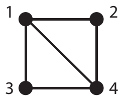


2. $\tau(K_{2,n}) = n2^{n-1}$. To confirm this, let $X = \{x_1, x_2\}$ and $|Y| = n$. The spanning tree contains a path of length 2 joining x_1 to x_2, whose middle vertex in Y can be chosen in n ways. For each of the remaining $n-1$ vertices of Y, there is a choice as to which of x_1 and x_2 is its neighbor (not both, since that would create a cycle).

3. $\tau(I_3 + K_2) = 5^3\left(1 - \frac{3}{5}\right)^2 = 20$.

4. $\tau(W_4) = \left(\frac{3+\sqrt{5}}{2}\right)^4 + \left(\frac{3-\sqrt{5}}{2}\right)^4 - 2 = 45$.

5. To illustrate the matrix-tree theorem, consider the following graph G. Then

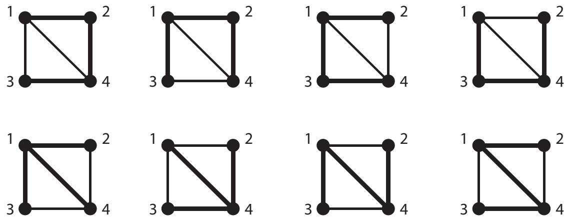


$$D(G) - A(G) = \begin{pmatrix} 3 & -1 & -1 & -1 \\ -1 & 2 & 0 & -1 \\ -1 & 0 & 2 & -1 \\ -1 & -1 & -1 & 3 \end{pmatrix}.$$

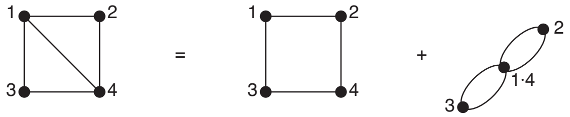
Deleting row 2 and column 3, for example, yields

$$\tau(G) = (-1)^{2+3}\begin{vmatrix} 3 & -1 & -1 \\ -1 & 0 & -1 \\ -1 & -1 & 3 \end{vmatrix} = 8.$$

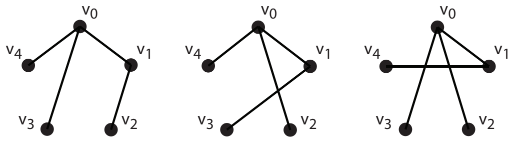
The eight spanning trees of G are



6. The recursive formula $\tau(G) = \tau(G-e) + \tau(G/e)$ is illustrated with the same graph G of the previous example and with $e = v_1v_4$. In the computation G is drawn instead of writing $\tau(G)$, and similarly with the other graphs. This yields



7. Let the vertices of K_5 be v_0, v_1, v_2, v_3, v_4. The number of spanning trees of K_5 in which the degrees of v_0, v_1, v_2, v_3, v_4 are $3, 2, 1, 1, 1$, respectively, is given by the multinomial coefficient $\binom{5-2}{3-1,2-1,1-1,1-1,1-1} = \frac{3!}{2!\cdot1!\cdot0!\cdot0!\cdot0!} = \frac{6}{2\cdot1\cdot1\cdot1\cdot1} = 3$. The three trees in question are



9.3 ENUMERATING TREES

Tree counting began with Arthur Cayley in 1889, who wanted to enumerate the saturated hydrocarbons. George Pólya developed an extensive theory in 1937 for counting families of organic chemicals, which was used by Richard Otter in 1948 in his solution of the specific problem of counting saturated hydrocarbons. Tree counting formulas are used in computer science to estimate running times in the design of algorithms.

9.3.1 COUNTING GENERIC TREES

When counting generic trees, we must be careful to distinguish among labeled trees, rooted trees, unlabeled trees, and various other objects. While labeled trees can be counted easily, unlabeled trees, both rooted and unrooted, are typically counted using generating functions.

Definitions:

A ***labeled tree*** is a tree in which distinct labels, typically $v_1, v_2, \ldots, v_n$, have been assigned to the vertices. Two labeled trees with the same set of labels are considered the same only if there is an isomorphism from one to the other that preserves the labels.

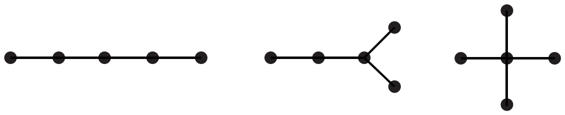
A ***rooted tree*** is a tree in which one vertex, the root, is distinguished. Two rooted trees are considered the same only if there is an isomorphism from one to the other that maps the root of the first to the root of the second.

A ***rooted labeled tree*** is a labeled tree in which one vertex, the root, is distinguished. Two rooted labeled trees with the same set of labels are considered the same only if there is an isomorphism from one to the other that preserves the labels and maps the root of the first to the root of the second.

A ***reduced tree*** (or ***irreducible tree***) is a tree with no vertices of degree 2.

Examples:

1. The figure below shows the three isomorphically distinct trees with five vertices. There are 60 essentially different ways to label each of the first two and five essentially different ways to label the third. Thus there are 125 different labeled trees with five vertices.



2. There are three essentially different ways to root the first tree in the figure of Example 1, four essentially different ways to root the second, and two essentially different ways to root the third. Thus there are nine rooted (unlabeled) trees with five vertices.

3. Each of the 125 labeled trees discussed in Example 1 can be rooted at any of its five vertices, yielding 625 possible rooted labeled trees.

4. The third tree in the figure of Example 1 is the only reduced tree with five vertices.

Facts:

1. The number of labeled trees with n vertices is n^{n-2}. See Table 1. This is sequence A000272 in [OEIS].

2. The number of rooted labeled trees with n vertices is n^{n-1}. See Table 1. This is sequence A000169 in [OEIS].

Table 1: Labeled trees and rooted labeled trees with n vertices.

n	Labeled Trees	Rooted Labeled Trees
1	1	1
2	1	2
3	3	9
4	16	64
5	125	625
6	1,296	7,776
7	16,807	117,649
8	262,144	2,097,152
9	4,782,969	43,046,721
10	100,000,000	1,000,000,000
11	2,357,947,691	25,937,424,601
12	61,917,364,224	743,008,370,688

n	Labeled Trees	Rooted Labeled Trees
13	1,792,160,394,037	23,298,085,122,481
14	56,693,912,375,296	793,714,773,254,144
15	1,946,195,068,359,375	29,192,926,025,390,625
16	72,057,594,037,927,936	1,152,921,504,606,846,980

3. Let R_n denote the number of (unlabeled) rooted trees with n vertices, and let $r(x)$ be the generating function for rooted trees, so that

$$r(x) = \sum_{n=1}^{\infty} R_n x^n = x + x^2 + 2x^3 + 4x^4 + 9x^5 + 20x^6 + \cdots .$$

The coefficients R_n of this generating function can be determined by means of the recurrence relation

$$r(x) = x \prod_{k=1}^{\infty} (1 - x^k)^{-R_k}.$$

See Table 2. This is sequence A000081 in [OEIS].

Table 2: Rooted trees, trees, and reduced trees with n vertices.

n	Rooted Trees	Trees	Reduced Trees
1	1	1	1
2	1	1	1
3	2	1	0
4	4	2	1
5	9	3	1
6	20	6	2
7	48	11	2
8	115	23	4

10	719	106	10
11	1,842	235	14
12	4,766	551	26
13	12,486	1,301	42
14	32,973	3,159	78
15	87,811	7,741	132
16	235,381	19,320	249
17	634,847	48,629	445
18	1,721,159	123,867	842
19	4,688,676	317,955	1,561
20	12,826,228	823,065	2,988
21	35,221,832	2,144,505	5,671
22	97,055,181	5,623,756	10,981
23	268,282,855	14,828,074	21,209
24	743,724,984	39,299,897	41,472

n	Rooted Trees	Trees	Reduced Trees
25	2,067,174,645	104,636,890	81,181
26	5,759,636,510	279,793,450	160,176
27	16,083,734,329	751,065,460	316,749
28	45,007,066,269	2,023,443,032	629,933
29	126,186,554,308	5,469,566,585	1,256,070
30	354,426,847,597	14,830,871,802	2,515,169

4. Let T_n denote the number of trees with n vertices, and let $t(x)$ be the generating function for trees, so that

$$t(x) = \sum_{n=1}^{\infty} T_n x^n = x + x^2 + x^3 + 2x^4 + 3x^5 + 6x^6 + \cdots .$$

The coefficients T_n of this generating function $t(x)$ can be determined from the generating function $r(x)$ for rooted trees in Fact 3 above by using the formula

$$t(x) = r(x) - \tfrac{1}{2}\left(r^2(x) - r(x^2)\right).$$

See Table 2. This is sequence A000055 in [OEIS].

5. Counting reduced trees requires an auxiliary sequence Q_n with generating function $q(x)$, so that

$$q(x) = \sum_{k=1}^{\infty} Q_k x^k = x + x^3 + x^4 + 2x^5 + 3x^6 + 6x^7 + 10x^8 + \cdots .$$

The coefficients Q_i of this generating function can be determined from the recurrence relation

$$q(x) = \frac{x}{1+x} \prod_{k=1}^{\infty} (1 - x^k)^{-Q_k}.$$

This is sequence A001678 in [OEIS].

6. Let H_n denote the number of reduced trees with n vertices, and let $h(x)$ be the generating function for reduced trees, so that

$$h(x) = \sum_{n=1}^{\infty} H_n x^n = x + x^2 + x^4 + x^5 + 2x^6 + 2x^7 + 4x^8 + \cdots .$$

The coefficients H_n of this generating function $h(x)$ can be determined from the auxiliary function $q(x)$ in Fact 5 above by using the formula

$$h(x) = (1+x)q(x) - \left(\frac{1+x}{2}\right) q^2(x) + \left(\frac{1-x}{2}\right) q(x^2).$$

See Table 2. Note that there are no reduced trees with exactly 3 vertices. This is sequence A000014 in [OEIS].

9.3.2 COUNTING TREES IN CHEMISTRY

Definitions:

A ***1-4 tree*** is a tree in which each vertex has degree 1 or 4.

A ***1-rooted 1-4 tree*** is a 1-4 tree rooted at a vertex of degree 1.

Remarks:

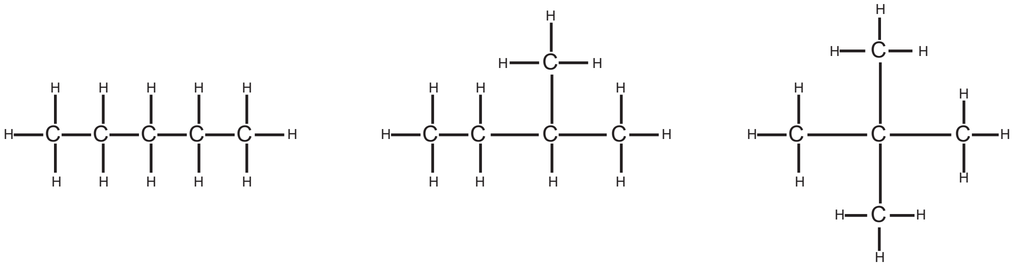
1. The 1-4 trees model many types of organic chemical molecules such as saturated hydrocarbons or alkanes. These molecules have the chemical formula C_nH_{2n+2} and consist of n carbon atoms of valence 4 and $2n+2$ hydrogen atoms of valence 1.

2. The 1-rooted 1-4 trees model the monosubstituted hydrocarbons such as the alcohols with the chemical formula $C_nH_{2n+1}OH$ and consisting of n carbon atoms, $2n+1$ hydrogen atoms, and an OH group.

3. It is convenient when counting alcohols to include the water molecule HOH as an honorary alcohol.

Examples:

1. The figure below shows the three different 1-4 trees with five vertices of degree 4 and 12 vertices of degree 1.



2. The first 1-4 tree in Example 1 can be rooted at a vertex of degree 1 in three essentially different ways, the second in four essentially different ways, and the third in essentially only one way. Thus there are eight different 1-rooted 1-4 trees with five vertices of degree 4.

Facts:

1. A 1-4 tree with n vertices of degree 4 always has $2n+2$ vertices of degree 1.

2. Let A_n denote the number of 1-rooted 1-4 trees with n vertices of degree 4, and let $a(x)$ be the generating function for the number of 1-rooted 1-4 trees, so that

$$a(x) = \sum_{n=0}^{\infty} A_n x^n = 1 + x + x^2 + 2x^3 + 4x^4 + 8x^5 + 17x^6 + \cdots .$$

The coefficients A_n of this generating function $a(x)$ can be determined from the recurrence relation

$$a(x) = 1 + \tfrac{x}{6}\left(a^3(x) + 3a(x)a(x^2) + 2a(x^3)\right).$$

See Table 3. This is sequence A000598 in [OEIS].

Table 3: 1-Rooted 1-4 trees and 1-4 trees with n vertices of degree 4.

n	1-Rooted 1-4 Trees	1-4 trees
1	1	1
2	1	1
3	2	1
4	4	2
5	8	3
6	17	5
7	39	9
8	89	18
9	211	35
10	507	75
11	1,238	159
12	3,057	355
13	7,639	802
14	19,241	1,858
15	48,865	4,347
16	124,906	10,359
17	321,198	24,894
18	830,219	60,523
19	2,156,010	148,284
20	5,622,109	366,319
21	14,715,813	910,726
22	38,649,152	2,278,658
23	101,821,927	5,731,580
24	269,010,485	14,490,245
25	712,566,567	36,797,588
26	1,891,993,344	93,839,412
27	5,034,704,828	240,215,803
28	13,425,117,806	617,105,614
29	35,866,550,869	1,590,507,121
30	95,991,365,288	4,111,846,763

3. Counting (unrooted) 1-4 trees requires first counting 1-4 trees rooted at a vertex of degree 4. Let Z_n be the number of 4-rooted 1-4 trees with n vertices of degree 4, and let $z(x)$ be the generating function for the number of 4-rooted 1-4 trees, so that

$$z(x) = \sum_{n=1}^{\infty} Z_n x^n = x + x^2 + 2x^3 + 4x^4 + 9x^5 + 18x^6 + \cdots \ .$$

The coefficients Z_n of this generating function $z(x)$ can be obtained by using the formula

$$z(x) = \tfrac{x}{24}\left(a^4(x) + 6a^2(x)a(x^2) + 8a(x)a(x^3) + 3a^2(x^2) + 6a(x^4)\right),$$

where $a(x)$ is the generating function for 1-rooted 1-4 trees from Fact 2. This is sequence A000678 in [OEIS].

4. Let B_n denote the number of (unrooted) 1-4 trees with n vertices of degree 4, and let $b(x)$ be the generating function for 1-4 trees, so that

$$b(x) = \sum_{n=0}^{\infty} B_n x^n = 1 + x + x^2 + x^3 + 2x^4 + 3x^5 + 5x^6 + \cdots .$$

The coefficients B_n of this generating function $b(x)$ can be determined from the functions $a(x)$ and $z(x)$ from Facts 2 and 3, respectively, by using the formula

$$b(x) = z(x) + a(x) - \tfrac{1}{2}\left(a^2(x) - a(x^2)\right).$$

See Table 3. This is sequence A000602 in [OEIS].

9.3.3 COUNTING TREES IN COMPUTER SCIENCE

Definitions:

A ***binary tree*** consists of a root vertex and at most two principal subtrees that are themselves binary trees. Each principal subtree must be specified as either the left subtree or the right subtree. The root vertex of a binary tree is joined by an edge to the root of each principal subtree.

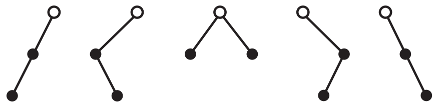
An ***ordered tree*** consists of a root vertex and a sequence $t_1, t_2, \ldots, t_m$ of $m \geq 0$ principal subtrees that are themselves ordered trees.

The ***children*** of the root vertex of an ordered tree or a binary tree are the roots of the principal subtrees.

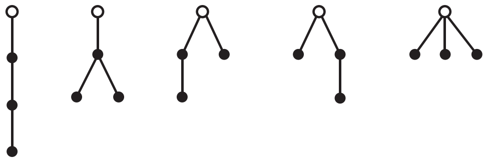
A ***full binary tree*** (sometimes called a ***left-right tree***) is a binary tree in which each vertex has either 0 or 2 children.

Examples:

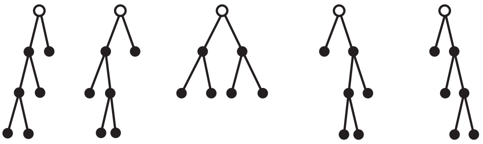
1. The following figure shows the five binary trees with three vertices.



2. The next figure shows the five ordered trees with four vertices.



3. The following figure shows the five full binary trees with seven vertices.



Remarks:

1. In computer science, trees are usually drawn with the root at the top.

2. Binary trees are easily represented in a computer. Other types of trees are often converted into binary trees for computer representation.

3. Ordered trees are used to represent structures such as family trees, showing all descendants of a person represented by the root. The roots of the principal subtrees represent the children of the root person, in order of birth.

4. Full binary trees are frequently used to represent arithmetic expressions, in which the leaves correspond to numbers and the other vertices represent binary operations such as $+$, $-$, $\times$, or $\div$.

Facts:

1. The number of binary trees with n vertices is the Catalan number C_n (see §3.1.3) given by the formula

$$C_n = \frac{1}{n+1}\binom{2n}{n} = \frac{(2n)!}{(n+1)!\,n!} \quad \text{for } n \geq 0.$$

See Table 4. This is sequence A000108 in [OEIS].

Table 4: The Catalan numbers.

n	C_n	n	C_n
1	1	17	129,644,790
2	2	18	477,638,700
3	5	19	1,767,263,190
4	14	20	6,564,120,420
5	42	21	24,466,267,020
6	132	22	91,482,563,640
7	429	23	343,059,613,650
8	1,430	24	1,289,904,147,324
9	4,862	25	4,861,946,401,452
10	16,796	26	18,367,353,072,152
11	58,786	27	69,533,550,916,004
12	208,012	28	263,747,951,750,360
13	742,900	29	1,002,242,216,651,368
14	2,674,440	30	3,814,986,502,092,304
15	9,694,845	31	14,544,636,039,226,909
16	35,357,670	32	55,534,064,877,048,198

2. The number of ordered trees with n vertices is the Catalan number C_{n-1}. See Table 4.

3. The number of full binary trees with $2n+1$ vertices is also C_n. See Table 4.

NETWORKS AND FLOWS

INTRODUCTION

The vertices and edges of a graph often have quantitative information associated with them, such as supplies and demands (for vertices), and distance, length, capacity, and cost (for edges). Relative to such networks, a number of discrete optimization problems arise in a variety of disciplines: statistics, electrical engineering, operations research, combinatorics, and computer science. Typical applications include designing least cost telecommunication systems, maximizing throughput in a manufacturing system, finding a minimum cost route or set of routes for delivery vehicles, and distributing electricity from a set of supply points to meet customer demands at minimum cost. In this chapter, a number of classical network optimization problems are studied and algorithms are described for their exact or approximate solution. Models and analysis of small-world networks are also presented.

GLOSSARY

adjacency matrix: a 0-1 matrix whose (i, j) entry indicates the absence or presence, respectively, of an arc joining vertex i to vertex j in a graph.

adjacency set: the set of arcs emanating from a specified vertex.

alternating path (in a matching): a path with edges that are alternately free and matched.

arc list: a list of the arcs of a graph, presented in no particular order.

assignment (from a set S to a set T): a bijective function from S onto T.

augmenting path (in a flow network): a directed path between two specified vertices in which each arc has a positive residual capacity.

augmenting path (in a matching): an alternating path between two free vertices.

backbone network: a collection of devices that interconnect vertices at which message exchanges occur in a communication network.

Barabási-Albert model: a model of network formation in which a new vertex is (preferentially) joined to existing vertices based on their current degree in the network.

blossom: an odd length cycle formed by adding an edge joining two even vertices on an alternating path.

blocking pair (relative to a matching): a currently unmatched pair of individuals, each of which prefers one another to their current mate in the matching.

capacitated concentrator location problem: an optimization problem in which a minimum cost configuration of concentrators and their connections to terminals are sought so that each concentrator's total capacity is not exceeded.

capacitated minimum spanning tree: a minimum cost collection of subtrees joined to a specified root vertex, in which the total amount of demand generated by each subtree is bounded above by a constant.

capacitated network: a network in which each arc is assigned a capacity.

capacity (of an arc): the maximum amount of material that can flow along the arc.

capacity (of a cut $[S, \overline{S}]$): the sum of the capacities of arcs (i, j) with $i \in S$ and $j \in \overline{S}$.

capacity (of a path): the smallest capacity of any arc on the path.

capacity assignment problem: an optimization problem in which links of different capacities are to be installed at minimum cost to support a number of point-to-point communication demands.

clustering coefficient (of a graph): a measure of the probability that two random neighbors of a vertex are neighbors of each other.

complete matching: in a bipartite graph $G = (X \cup Y, E)$, a matching M in which each vertex of X is incident with an edge of M.

composite (***hybrid***) ***method***: a heuristic algorithm that combines elements of both construction methods and improvement methods.

configuration model: a model that generates graphs by randomly connecting half-edges in a graph having a given degree sequence.

connected facility location problem: an optimization problem in which certain facilities are to be opened and customers assigned to them at minimum total cost.

construction method: a heuristic algorithm that builds a feasible solution, starting with a trivial configuration.

cost (of a flow): $\sum_{(i,j)} c_{ij} x_{ij}$, where c_{ij} is the cost and x_{ij} is the flow on arc (i, j).

cut (in a graph): the set of edges $[S, \overline{S}]$ in the graph joining vertices in S to vertices in the complementary set $\overline{S}$.

degree distribution (of a graph): the proportion of vertices having each degree in the graph.

directed network: a vertex set V and an arc set E, where each directed arc has an associated cost, length, weight, or capacity.

directed out-tree: a tree rooted at vertex s such that the unique path in the tree from vertex s to every other vertex is a directed path.

distance label: an estimate (in particular, an upper bound) on the shortest path length from the source vertex to each network vertex.

Dorogovtsev-Mendes model: a small-world network model that constructs a regular (low-dimensional) lattice and then adds an extra vertex, randomly connected to existing vertices in the lattice.

even vertex (in an alternating path P): a vertex on P that is reached using an even number of edges of P, starting from the origin vertex of P.

exact algorithm: a procedure that produces a verifiable optimal solution to every problem instance.

flow: a feasible assignment of material that satisfies flow conservation and arc capacity restrictions.

forward star: a compact representation of a graph in which information about arcs leaving a vertex is stored using consecutive locations of an array.

free edge (in a matching): an edge that does not appear in the matching.

free vertex (in a matching): a vertex that is not incident with any matched edge.

generalized random graph model: a model that generates graphs by adding edges with probability proportional to the product of the given vertex degrees.

heuristic algorithm: a procedure that produces a feasible, though not necessarily optimal, solution to every problem instance.

improvement method: a heuristic algorithm that starts with a suboptimal solution (often randomly generated) and attempts to improve it.

Jackson-Rogers model: a two-step model of network formation in which a new vertex is joined randomly to a set of parental vertices and then is joined to some of the neighbors of these parental vertices.

Kleinberg small-world model: a modified version of the Newman-Watts model in which edges are randomly added, based on the network distance between their associated vertices.

Klemm-Eguíluz model: a model of network formation in which a new vertex is joined either to an existing vertex or to a dynamically changing set of active vertices.

length (of a path): the sum of all costs appearing on the arcs of the path.

linear assignment problem (LAP): an optimization problem in which an assignment is sought that minimizes an appropriate set-up cost.

link capacity: an upper bound on the amount of traffic that a communication link can carry at any one time.

linked adjacency list: a collection of singly-linked lists used to represent a graph.

local access network: a network used to transfer traffic between the backbone network and the end users.

matched edge (in a matching): an edge that appears in the matching.

matched vertex (in a matching): a vertex that is incident with a matched edge.

matching (in a graph): a set of pairwise nonadjacent edges in the graph.

mate (of a matched vertex): in a matching, the other endpoint of the matched edge incident with the given vertex.

maximum flow (in a network): a flow in the network having maximum value.

maximum size matching: a matching having the largest size.

maximum spanning tree (of a network): a spanning tree of the network with maximum cost.

maximum weight matching: a matching having the largest weight.

metaheuristic: a general-purpose heuristic procedure (such as tabu search, simulated annealing, genetic algorithms, or neural networks) for solving difficult optimization problems.

minimum cost flow (in a network): a flow in the network having minimum cost.

minimum cut (in a network): a cut in the network having minimum capacity.

minimum spanning tree (of a network): a spanning tree of the network with minimum cost.

negative cycle: a directed cycle of negative cost (or length).

network design problem: an optimization problem in which a minimum cost assignment of different capacity cables to edges is sought that satisfies given point-to-point demands and that respects all edge capacities.

Newman-Watts model: a small-world network model that constructs a regular (low-dimensional) lattice and then adds a random number of extra edges.

odd vertex (in an alternating path P): a vertex on P that is reached using an odd number of edges of the path P, starting from the origin vertex of P.

perfect matching: a matching in a graph in which each vertex of the graph is incident with exactly one edge of the matching.

power-law distribution: a distribution in which the proportion p_k of vertices having degree k is given by $p_k = Ck^{-\beta}$ for some fixed parameter β.

predecessor: relative to a rooted tree, the vertex preceding a given vertex on the unique path from the root to the given vertex.

preflow: a relaxation of flow where inflow into a vertex can be greater than its outflow.

pseudoflow: a relaxation of flow where inflow into a vertex need not be equal to its outflow.

quadratic assignment problem (***QAP***): an optimization problem in which an assignment is sought that minimizes the sum of set-up and interaction costs.

random graph: a graph obtained by randomly adding edges between a fixed number of vertices.

reduced cost of arc (i, j): relative to given vertex potentials π, the quantity $c_{ij}^{\pi} = c_{ij} - \pi(i) + \pi(j)$.

regenerator location problem: an optimization problem in which a minimum cost placement of regenerators is sought so that all terminal vertices can communicate with one another without loss of signal quality.

regular lattice: a graph obtained by placing regularly-spaced vertices and then joining each vertex to its closest neighbors.

residual capacity (of an arc): the maximum additional flow (with respect to a given flow) that can be sent on an arc.

residual network: a network consisting of arcs with positive residual capacity.

s-t cut: a cut $[S, \overline{S}]$ in which $s \in S$ and $t \in \overline{S}$.

savings: the reduction in cost from joining two vertices directly compared to joining both to a central vertex.

shortest path: a directed path between specified vertices having minimum total cost (or length).

size (of a matching): the number of edges in the matching.

stable matching: a matching that contains no blocking pairs.

stable partners: individuals that are matched in some stable matching.

survivable network: a network that can survive failures in some of its vertices or edges and still transfer a prespecified amount of traffic.

traveling salesman problem (***TSP***): an optimization problem in which a fixed set of cities must be visited in some order at minimum total cost.

two-phase method: a heuristic algorithm that implements a cluster first/route second philosophy.

undirected network: a vertex set V and an edge set E, where each undirected edge has an associated cost, length, weight, or capacity.

value of a flow: the total flow leaving the source vertex.

vehicle routing problem (***VRP***): an optimization problem in which a given set of customers must be serviced at minimum total cost, using a fleet of vehicles having fixed capacity.

vertex potential: a quantity $\pi(i)$ associated with each vertex i of a network.

Watts-Strogatz model: a small-world network model that constructs a regular (low-dimensional) lattice and then repositions a random number of its edges.

weight (of a matching): the sum of the weights of edges in the matching.

10.1 MINIMUM SPANNING TREES

In an undirected network, the minimum spanning tree problem is the problem of identifying a spanning tree of the network that has the smallest possible sum of edge costs. This problem arises in a number of applications, both as a stand-alone problem and as a subproblem in more complex problem settings. It is assumed throughout this section that the network is connected.

10.1.1 BASIC CONCEPTS

Definitions:

An ***undirected network*** is a weighted graph (§8.1.1) $G = (V, E)$, where V is the set of vertices, E is the set of undirected edges, and each edge $(i, j) \in E$ has an associated ***cost*** (or ***weight***, ***length***) c_{ij}. Let $n = |V|$ and $m = |E|$.

If $T = (V, F)$ is a spanning tree (§9.2) of $G = (V, E)$, then every edge in $F \subseteq E$ is a ***tree edge*** and every edge in $E - F$ is a ***nontree edge*** (or ***chord***).

A ***minimum spanning tree*** (***MST***) of G is a spanning tree of G for which the sum of the edge costs is minimum.

A ***maximum spanning tree*** of G is a spanning tree of G for which the sum of the edge costs is maximum.

A ***cut*** of $G = (V, E)$ is a partition of the vertex set V into two parts, S and $\overline{S} = V - S$. Each cut defines the set of edges $[S, \overline{S}] \subseteq E$ having one endpoint in S and the other endpoint in $\overline{S}$.

Facts:

1. Every spanning tree T of a network G with n vertices contains exactly $n-1$ edges, and every two vertices of T are connected by a unique path.

2. Adding an edge to a spanning tree of G produces a unique cycle, called a *fundamental cycle* (§9.2.1).

3. Every cut $[S, \overline{S}]$ is a disconnecting set of edges (§8.4.2). However, not every disconnecting set of edges can be represented as a cut $[S, \overline{S}]$; see Example 4.

4. Removing an edge from a spanning tree of G produces two subtrees, on vertex sets S and $\overline{S}$, respectively. The associated cut $[S, \overline{S}]$ is called a *fundamental cut*.

5. *Path optimality conditions*: A spanning tree T^* is a minimum spanning tree of G if and only if for each nontree edge (k, l) of G, $c_{ij} \leq c_{kl}$ holds for all tree edges (i, j) in the fundamental cycle determined by edge (k, l).

6. *Cut optimality conditions*: A spanning tree T^* is a minimum spanning tree of G if and only if for each tree edge $(i, j) \in T^*$, $c_{ij} \leq c_{kl}$ holds for all nontree edges (k, l) in the fundamental cut determined by edge (i, j).

7. If all edge costs are different, then the minimum spanning tree is unique.

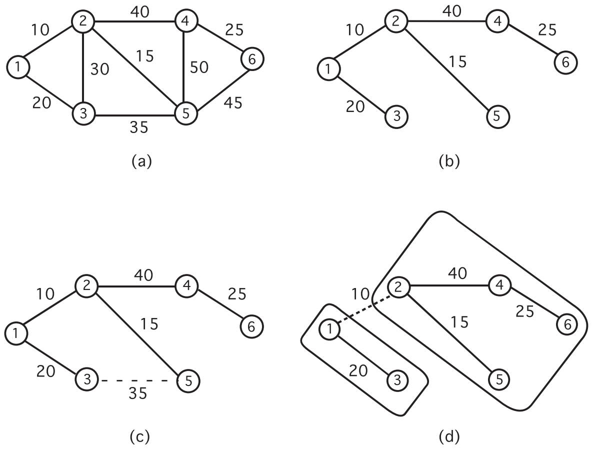
8. The minimum spanning tree can be unique even if some of the edge costs are equal; see Example 3.

9. Adding a constant to all edge costs of an undirected network does not change the minimum spanning tree(s) of the network. Thus, it is sufficient to have an algorithm that works when all edge costs are positive.

10. Multiplying each edge cost of an undirected network by -1 converts a maximum spanning tree into a minimum spanning tree, and vice versa. Thus, it is sufficient to have algorithms to find a minimum spanning tree.

Examples:

1. Part (a) of the following figure shows an undirected network G, with costs indicated on each edge. Part (b) shows a spanning tree T^* of G.

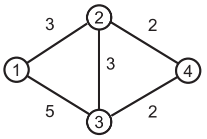


(a) (b) (c) (d)

Adding the nontree edge $(3, 5)$ to T^* produces the fundamental cycle $[3, 1, 2, 5, 3]$; see part (c). Since each tree edge in this cycle has cost no more than that of the nontree edge $(3, 5)$, the path optimality condition is satisfied by edge $(3, 5)$. Similarly, it can be verified that the other nontree edges, namely $(2, 3)$, $(4, 5)$, and $(5, 6)$, satisfy the path optimality conditions, establishing by Fact 5 that T^* is a minimum spanning tree. By Fact 7 this is the unique minimum spanning tree.

2. For the tree edge $(1,2)$ in part (b) of the figure of Example 1, the fundamental cut $[S,\overline{S}]$ formed by deleting edge $(1,2)$ has $S=\{1,3\}$ and $\overline{S}=\{2,4,5,6\}$; see part (d) of the figure. This cut contains two nontree edges, $(2,3)$ and $(3,5)$. Since each such nontree edge has cost greater than or equal to that of the tree edge $(1,2)$, the cut optimality condition is satisfied for edge $(1,2)$. Similarly, it can be verified that the other tree edges, namely $(1,3)$, $(2,4)$, $(2,5)$, and $(4,6)$, satisfy the cut optimality conditions, establishing by Fact 6 that T^* is a minimum spanning tree.

3. The undirected network in part (a) of the following figure has four vertices and five edges, with the edge cost shown beside each edge. This network contains eight spanning trees, which are listed in the table in part (b) of the figure. The spanning tree T_5 achieves the minimum cost 7 among all the spanning trees and so is a minimum spanning tree. In fact, T_5 is the unique minimum spanning tree, even though the edge costs are not all distinct. See Fact 8.



(a)

	Spanning Tree Edges	Total Cost
T_1	(1,2), (1,3) (2,4)	10
T_2	(1,2), (1,3) (3,4)	10
T_3	(1,2), (2,3) (2,4)	8
T_4	(1,2), (2,3) (3,4)	8
T_5	(1,2), (2,4) (3,4)	7
T_6	(1,3), (2,3) (2,4)	10
T_7	(1,3), (2,3) (3,4)	10
T_8	(1,3), (2,4) (3,4)	9

(b)

4. The set of edges $F=\{(1,2),(2,4),(3,4)\}$ is a disconnecting set in the network G of Example 3, since removal of these edges disconnects G. However, there is no partition of the vertex set of G into nonempty sets S and $\overline{S}$ for which $F=[S,\overline{S}]$.

10.1.2 ALGORITHMS FOR MINIMUM SPANNING TREES

There are several greedy algorithms for constructing minimum spanning trees, based on the optimality conditions in §10.1.1, Facts 5 and 6. Each of these algorithms myopically (greedily) adds an edge to the current configuration based on only local information; nonetheless, these procedures are guaranteed to produce a minimum spanning tree.

Definitions:

The ***nearest neighbor*** operation takes as input a tree T^* having vertex set S and produces a minimum cost edge (i,j) in the cut $[S,\overline{S}]$; i.e., $c_{ij}=\min\{c_{ab}\mid a\in S,\ b\notin S\}$.

The ***merge*** operation takes as input an edge (i,j) whose two endpoints i and j belong to disjoint trees T_i and T_j and combines the trees into $T_i\cup T_j\cup\{(i,j)\}$.

The graph $G=(V,E)$ is assumed connected, with n vertices and m edges.

Facts:

1. *Kruskal's algorithm*: This greedy algorithm (Algorithm 1) is based on the path optimality conditions (§10.1.1) and builds a minimum spanning tree by examining edges of E one by one in nondecreasing order of their costs. The edge being examined is added to the current forest if its addition does not create a cycle. (J. B. Kruskal, 1928–2010)

Algorithm 1: **Kruskal's algorithm.**

```
input: connected undirected network $G$
output: minimum spanning tree $T^*$
order the edges $(i_1, j_1), (i_2, j_2), \ldots, (i_m, j_m)$ so that $c_{i_1 j_1} \le c_{i_2 j_2} \le \cdots \le c_{i_m j_m}$
$T^* := \emptyset$
for $k := 1$ to $m$
  if $T^* \cup \{(i_k, j_k)\}$ does not contain a cycle then $T^* := T^* \cup \{(i_k, j_k)\}$
```

2. Kruskal's algorithm can be terminated once $n - 1$ edges have been added to T^*.

3. Kruskal's algorithm can be implemented in $O(m \log n)$ time. The bottleneck operation is sorting of the edge costs.

4. Algorithm 1 was independently discovered by Kruskal (1956) and by H. Loberman and A. Weinberger (1957).

5. *Prim's algorithm*: This algorithm (Algorithm 2) is based on the cut optimality conditions (§10.1.1). It maintains a single tree T^*, which initially consists of an arbitrary vertex i_0. At each iteration, the algorithm adds the least cost edge emanating from T^* until a spanning tree is obtained. (R. C. Prim, born 1921)

Algorithm 2: **Prim's algorithm.**

```
input: connected undirected network $G$, vertex $i_0$
output: minimum spanning tree $T^*$
$T^*$ := the tree consisting of vertex $i_0$
while $|T^*| < n - 1$
  $(i, j) :=$ nearest_neighbor$(T^*)$
  $T^* := T^* \cup \{(i, j)\}$
```

6. Algorithm 2 was first proposed in 1930 by V. Jarník. Later it was independently discovered by Prim (1957) and by E. W. Dijkstra (1959).

7. Running times of several implementations of Prim's algorithm are shown in the following table. See [AhMaOr93] for a discussion of these implementations.

data structure	*running time*
binary heap	$O(m \log n)$
d-heap	$O(m \log_d n)$, with $d = \max\{2, \lceil \frac{m}{n} \rceil\}$
Fibonacci heap	$O(m + n \log n)$

8. *Sollin's algorithm*: This greedy algorithm (Algorithm 3) is also based on the cut optimality conditions (§10.1.1). It starts with a forest of n trees, each consisting of a single vertex, and builds a minimum spanning tree by repeatedly adding edges to the current forest. At each iteration a least cost edge emanating from each tree is added, leading to the merging of certain trees.

```
Algorithm 3: Sollin's algorithm.
  input: connected undirected network $G$
  output: minimum spanning tree $T^*$
  $T^*$ := forest of all vertices of $G$, but no edges
  while $|T^*| < n - 1$
    let $T_1, T_2, \ldots, T_p$ be the trees in the forest $T^*$
    for $k := 1$ to $p$
      $(i_k, j_k) := nearest\_neighbor(T_k)$
    for $k := 1$ to $p$
      if $i_k$ and $j_k$ belong to different trees then
        $merge(i_k, j_k)$
        $T^* := T^* \cup \{(i_k, j_k)\}$
```

9. Each iteration of Algorithm 3 reduces the number of trees in the forest T^* by at least half.

10. Sollin's algorithm performs $O(\log n)$ iterations and can be implemented to run in $O(m \log n)$ time; see [AhMaOr93].

11. A variation of Sollin's algorithm that runs in time $O(m \log \log n)$ can be found in [Ya75].

12. The origins of Algorithm 3 can be traced to O. Borůvka (1926), who first formulated the minimum spanning tree problem in the context of electric power networks. This algorithm was independently proposed in 1938 by G. Choquet for points in a metric space and by G. Sollin in 1961 for arbitrary networks.

13. Sollin's algorithm can be easily parallelized in EREW (exclusive-read, exclusive-write) PRAM (parallel random access machine). (See §17.1.4.) This algorithm assigns a processor to each edge and each vertex of the network [KiLe88].

14. Chong, Han, and Lam [ChHaLa01] developed an algorithm that runs in $O(\log n)$ time using m parallel processors. This running time is best possible.

15. Computational studies have found that the Prim and Sollin algorithms consistently outperform Kruskal's algorithm. Prim's algorithm is faster when the network is dense, whereas Sollin's algorithm is faster when the network is sparse.

16. An excellent discussion of the history of the minimum spanning tree problem is provided in [GrHe85].

17. The fastest deterministic algorithms for the minimum spanning tree problem are due to Chazelle [Ch00] and to Pettie and Ramachandran [PeRa02]. Chazelle's algorithm runs in $O(m\alpha(n, m))$ time where $\alpha(n, m)$ is the inverse Ackermann function, which for all practical purposes is less than 5. Pettie and Ramachandran show how to find a minimum spanning tree in $O(T^*(n, m))$ time, where $T^*(n, m)$ is the minimum number of edge-weight comparisons needed to determine the solution.

18. Karger, Klein, and Tarjan [KaKlTa95] developed a randomized algorithm for the minimum spanning tree problem that runs in $O(m)$ time.

19. Computer codes that implement spanning tree algorithms can be found at

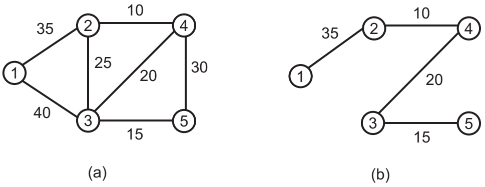
- `http://www3.cs.stonybrook.edu/~algorith/files/minimum-spanning-tree.shtml`

20. An important variant of the minimum spanning tree problem places constraints on the number of edges incident with a vertex in a candidate spanning tree. Such *degree-constrained* minimum spanning trees are investigated in [GlKl75] and [Vo89].

21. Another variant is the *capacitated* minimum spanning tree problem, which arises in the design of local access telecommunication networks. In this problem, a feasible spanning tree is one rooted at a specified central vertex such that the total traffic (number of calls) generated by each subtree connected to the central vertex does not exceed a known capacity. A feasible spanning tree having minimum total cost is then sought. (See §10.6.1 for further details.)

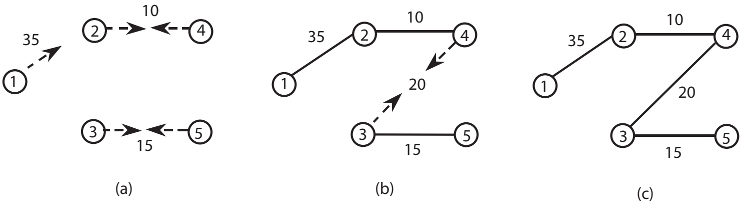
Examples:

1. For the network shown in part (a) of the following figure, ordering edges by nondecreasing cost produces the following sequence of edges: $(2,4)$, $(3,5)$, $(3,4)$, $(2,3)$, $(4,5)$, $(1,2)$, $(1,3)$. Kruskal's algorithm adds the edges $(2,4)$, $(3,5)$, $(3,4)$ to T^*; discards the edges $(2,3)$ and $(4,5)$; then adds the edge $(1,2)$ to T^* and terminates. Part (b) of the figure shows the resulting minimum spanning tree, having total cost 80.



2. Prim's algorithm (Algorithm 2) is applied to the network in part (a) of the figure for Example 1, starting with the initial vertex $i_0 = 3$. The minimum cost edge out of vertex 3 is $(3,5)$, so $T^* = \{(3,5)\}$. Next, the minimum cost edge emanating from T^* is $(3,4)$, giving $T^* = \{(3,5),(3,4)\}$. Subsequent iterations add the edges $(2,4)$ and $(1,2)$, producing the minimum spanning tree $T^* = \{(3,5),(3,4),(2,4),(1,2)\}$. Starting from any other initial vertex i_0 would give the same result.

3. To apply Sollin's algorithm (Algorithm 3) to the network in part (a) of the figure for Example 1, begin with a forest containing five trees, each consisting of a single vertex. Part (a) of the following figure shows the least cost edge emanating from each of these trees. One iteration of Algorithm 3 produces the two trees shown in part (b) of the following figure. The least cost edge emanating from either of these two trees is $(3,4)$. Adding this edge completes the minimum spanning tree shown in part (c) of the figure.



10.1.3 APPLICATIONS

Minimum spanning tree problems arise both directly and indirectly. For direct applications, the points in a given set are to be connected using the least cost collection of edges. For indirect applications, creative modeling of the original problem recasts it as a minimum spanning tree problem.

Applications:

1. *Designing physical systems*: A minimum cost network is to be designed to connect geographically dispersed system components. Each component is represented by a vertex, with potential network connections between vertices represented by edges. A cost is associated with each edge.

2. Examples of Application 1 occur in the following:

- Connect terminals in cabling the panels of electrical equipment in order to use the least total cost of wire.
- Construct a pipeline network to connect a number of towns using the smallest possible total cost of pipeline.
- Link isolated villages in a remote region, which are connected by roads but not yet by telephone service. The problem is to determine along which stretches of roads to place telephone lines to link every pair of villages, using the minimum total miles of installed lines.
- Construct a digital computer system, composed of high-frequency circuitry, when it is important to minimize the length of wires between different components to reduce both capacitance and delay line effects.
- Connect a number of computer sites by high-speed lines. Each line is available for leasing at a certain monthly cost, and a configuration is required that connects all the sites at minimum overall cost.
- Design a backbone network of high-capacity links that connect switching devices to support internet traffic. A minimum cost backbone network that maintains acceptable throughput is required.

3. *Clustering*: Objects having k measurable characteristics are to be clustered into groups of "similar" objects. First, construct an undirected network, where each object is represented by a vertex and every two distinct vertices are joined by an edge. The cost of edge (i, j) is the distance (in k-dimensional space) between the k-vectors for objects i and j. Applying Kruskal's algorithm to this network then yields a hierarchy of partitions of the vertex set; each partition is defined by the trees comprising the forest obtained at each iteration of Kruskal's algorithm. Such a hierarchy is then used to define clusters of the original objects. This application has been used to represent multidimensional gene expression data [XuOlXu02].

4. Computation of minimum spanning trees sometimes arises as a subproblem in a larger optimization problem. For example, one heuristic approach to the *traveling salesman problem* (§10.7.1) involves the calculation of minimum spanning trees.

5. *Optimal message passing*: An intelligence service has agents operating in a non-friendly country. Each agent knows some of the other agents and has in place procedures for arranging a rendezvous with someone he knows. For each such possible rendezvous, say between agent i and agent j, any message passed between these agents will fall into hostile hands with a certain probability p_{ij}. The group leader wants to transmit a confidential message among all the agents while maximizing the probability that no message is intercepted.

If the agents are represented by vertices and each possible rendezvous by an edge, then in the resulting graph G a spanning tree T is required that maximizes the probability that no message is intercepted, given by $\Pi_{(i,j)\in T}(1 - p_{ij})$. Such a tree can be found by defining the cost of each edge (i, j) as $\log(1 - p_{ij})$ and solving a *maximum* spanning tree problem.

6. *All-pairs minimax path problem*: In this variant of the shortest path problem (see §10.3.1), the value of a path P is the maximum cost of an edge in P. The all-pairs minimax path problem is to determine a minimum value path between every pair of vertices in a network G. It can be shown that if T^* is a minimum spanning tree of G, then the unique path in T^* between any pair of vertices is also a minimax path between that pair of vertices.

7. Examples of Application 6 arise in the following contexts:

- Determine the trajectory of a spacecraft that keeps the maximum temperature of the surface as small as possible.
- When traveling through a desert, select a route that minimizes the length of the longest stretch between rest areas.
- A person traveling in a wheelchair desires a route that minimizes the maximum ascent along the path segments of the route.

8. *Measuring homogeneity of bimetallic objects*: In this application minimum spanning trees are used to determine the degree to which a bimetallic object is homogeneous in composition. First, the composition of the bimetallic object is measured at a set of sample points. A network is then constructed with vertices corresponding to the sample points and with an edge connecting physically adjacent sample points. The cost of edge (i, j) is the product of the physical (Euclidean) distance between sample points i and j, and a homogeneity factor between 0 and 1. The homogeneity factor is 0 if the composition of the corresponding samples is identical, and is 1 if the composition is very different. This cost structure gives greater weight to two points if they have different compositions and are far apart. Then the cost of the minimum spanning tree provides an overall measure of the homogeneity of the object.

10.2 MATCHINGS

In an undirected network, the maximum matching problem is to find a set of nonadjacent edges that has the largest total size or weight. This discrete optimization problem arises in a number of applications, often involving the optimal pairing of a set of objects.

10.2.1 BASIC CONCEPTS

Definitions:

Let $G = (V, E)$ be an undirected network with vertex set V and edge set E (see §10.1.1). Assume that G contains neither loops nor multiple edges. Each edge $e = (i, j) \in E$ has an associated ***weight*** $w_e = w_{ij}$. Let $n = |V|$ and $m = |E|$.

The ***degree*** of vertex $v \in V$ in G is the number of edges in G that are incident with v, written $deg(v)$. (See §8.1.1.)

A ***matching*** in $G = (V, E)$ is a set $M \subseteq E$ of pairwise nonadjacent edges (§8.1.1).

A ***perfect matching*** in $G = (V, E)$ is a matching M in which each vertex of V is incident with exactly one edge of M.

A ***vertex cover*** in $G = (V, E)$ is a set S of vertices such that every edge of G is incident with some vertex in S.

The ***size*** (***cardinality***) of a matching M is the number of edges in M, written $|M|$.

The ***weight*** of a matching M is $wt(M) = \sum_{e \in M} w_e$.

A ***maximum size*** matching of G is a matching M having the largest size $|M|$.

A ***maximum weight*** matching of G is a matching M having the largest weight $wt(M)$.

Relative to a matching M in $G = (V, E)$, edges $e \in M$ are ***matched*** edges, while edges $e \in E - M$ are ***free*** edges. Vertex v is ***matched*** if it is incident with a matched edge; otherwise vertex v is ***free***.

Every matched vertex v has a ***mate***, the other endpoint of the matched edge incident with v.

With respect to a matching M, the ***weight*** $wt(P)$ of path P is the sum of the weights of the free edges in P minus the sum of the weights of the matched edges in P.

An ***alternating*** path has edges that are alternately free and matched. An ***augmenting*** path is an alternating path that starts and ends at a free vertex.

Facts:

1. Matchings are useful in a wide variety of applications, such as assigning personnel to jobs, target tracking, crew scheduling, snowplowing streets, scheduling on parallel machines, among others (see §10.2.5).

2. In a matching M, each vertex of G has degree 0 or 1 relative to the edges in M. In a perfect matching M, each vertex of G has degree 1 relative to the edges in M.

3. Any matching M of G contains $2|M|$ matched vertices and $n - 2|M|$ free vertices.

4. If M is any matching in G, then $|M| \leq \lfloor \frac{n}{2} \rfloor$.

5. *Weak duality theorem*: The size of any vertex cover for G is an upper bound on the size of any matching in G. As a result, the minimum size of a vertex cover is at least as large as the size of a maximum matching.

6. Every augmenting path has an odd number of edges.

7. If M is a matching and P is an augmenting path with respect to M, then the symmetric difference (§1.2.2) $M \Delta P$ is a matching of size $|M| + 1$.

8. If M is a matching and P is an augmenting path with respect to M, then $wt(M\Delta P) = wt(M) + wt(P)$.

9. *Augmenting path theorem*: M is a maximum size matching if and only if there is no augmenting path with respect to M.

10. Fact 9 was obtained independently by C. Berge (1957) and also by R. Z. Norman and M. O. Rabin (1959). This result was also recognized in an 1891 paper of J. Petersen.

11. Suppose M is a matching having maximum weight among all matchings of a fixed size k. If P is an augmenting path of maximum weight, then $M\Delta P$ is a matching having maximum weight among all matchings of size $k+1$.

12. Suppose paths $P_1, P_2, \ldots, P_k$ are obtained as in Fact 11 by augmenting along a maximum weight path. Then $wt(P_1) \geq wt(P_2) \geq \cdots \geq wt(P_k)$.

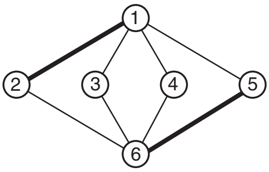
13. *Weighted augmenting path theorem*: M is a maximum weight matching if and only if there is no augmenting path with respect to M that has positive weight.

14. The number of perfect matchings of the complete graph (§8.1.3) K_{2n} on $2n$ vertices is $(2n-1)!! = 1 \cdot 3 \cdot 5 \ldots (2n-1)$.

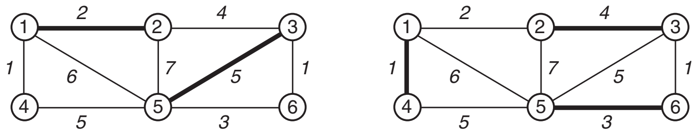
15. An historical perspective on the theory of matchings is found in [Pl92].

Examples:

1. The graph G in the following figure has six vertices and eight edges. The highlighted edges display a matching M of size 2. By Fact 4, the size of any matching in G is at most 3. Since the set $S = \{1,6\}$ of vertices form a vertex cover for G of size 2, Fact 5 shows that M is actually a maximum size matching and S is a minimum size vertex cover.



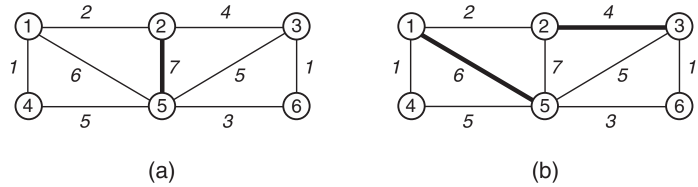
2. Part (a) of the following figure displays a network G with the weight w_e shown next to each edge e.



(a) (b)

The matching $M_1 = \{(1,2),(3,5)\}$ of size 2 is also shown, with the matched edges highlighted. The mate of vertex 1 is vertex 2, and the mate of vertex 5 is vertex 3. The weight of M_1 is $wt(M_1) = 7$. Relative to the matching M_1, vertices 4 and 6 are free vertices, and an augmenting path P from 4 to 6 is given by the set of edges $P = \{(1,4),(1,2),(2,3),(3,5),(5,6)\}$. Here $wt(P) = 1+4+3-2-5 = 1$ and (as guaranteed by Fact 6) path P has an odd number of edges. The matching $M_2 = M_1\Delta P = \{(1,2),(3,5)\}\,\Delta\,\{(1,4),(1,2),(2,3),(3,5),(5,6)\} = \{(1,4),(2,3),(5,6)\}$ is a perfect matching and is highlighted in part (b) of the figure. There are no free vertices relative to matching M_2 and no augmenting paths, so M_2 is a maximum size matching of G. There are other maximum size matchings, such as $\{(1,4),(2,5),(3,6)\}$ and $\{(1,2),(4,5),(3,6)\}$.

3. Part (a) of the following figure shows a matching M_1 of size 1, with $wt(M_1) = 7$. Since edge $(2,5)$ has maximum weight among all edges, M_1 is a maximum weight matching of size 1. Relative to M_1 the augmenting path $P_1 = \{(1,5),(2,5),(2,3)\}$ has weight $6+4-7=3$, whereas the augmenting path $\{(3,6)\}$ has weight 1. It can be verified that P_1 is a maximum weight augmenting path relative to M_1. By Fact 11, $M_2 = M_1 \Delta P_1 = \{(1,5),(2,3)\}$ is a maximum weight matching of size 2 in the network, with $wt(M_2) = wt(M_1) + wt(P_1) = 7+3 = 10$; see part (b) of the figure.



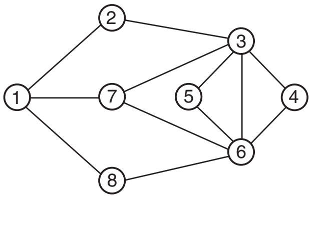
Relative to M_2 there are several augmenting paths between the free vertices 4 and 6:

$$\begin{aligned} Q_1 &= \{(1,4),(1,5),(5,6)\}, & wt(Q_1) &= 1+3-6 = -2,\\ Q_2 &= \{(1,4),(1,5),(2,5),(2,3),(3,6)\}, & wt(Q_2) &= 1+7+1-6-4 = -1,\\ Q_3 &= \{(4,5),(1,5),(1,2),(2,3),(3,6)\}, & wt(Q_3) &= 5+2+1-6-4 = -2. \end{aligned}$$

The maximum weight augmenting path is Q_2 and so (by Fact 11) $M_3 = M_2 \Delta Q_2 = \{(1,4),(2,5),(3,6)\}$ is a maximum weight matching of size 3 in the network with $wt(M_3) = 9$. Overall, the maximum weight matching in G is M_2 as expected, since all augmenting paths relative to M_2 have negative weight (see Fact 12).

4. *Paired kidney donations*: To address the severe shortage of organs for use in kidney transplants, some hospitals have organized a paired kidney donation program. While a relative of a patient would gladly donate a kidney to that patient, it may not be possible because of incompatibilities in blood type or unfavorable antibody reactions.

This situation can be illustrated using the following graph G. Each of the eight vertices in G represents a pair of incompatible donor-recipients. Two vertices are connected by an edge if the donors D of each pair are compatible matches for the recipients R of the other pair. For example, the edge $(1,2)$ indicates that D_1 can donate a kidney to R_2 and that D_2 can donate a kidney to R_1. A largest number of compatible kidney exchanges then corresponds to a maximum size matching in G. By Fact 4, there can be at most four compatible matches. However, $S = \{1,3,6\}$ is a vertex cover for G, meaning a maximum size matching can have size at most 3 (Fact 5). Consequently, at most three compatible matches are possible in this situation—for example, the pairs $(1,2)$, $(3,7)$, $(6,8)$.



10.2.2 MATCHINGS IN BIPARTITE NETWORKS

In this section, algorithms are described for finding maximum size and maximum weight matchings in bipartite networks (§8.1.3). Bipartite networks arise in a number of applications, such as in assigning personnel to jobs or tracking objects over time. Moreover, the algorithms developed for the case of bipartite networks are considerably simpler than those needed for the case of general networks (§10.2.3).

Definitions:

Let $G = (X \cup Y, E)$ be a bipartite network with n vertices and m edges, and edge weights w_{xy}.

If $S \subseteq X$ then $\Gamma(S) = \{y \in Y \mid (x, y) \in E$ for some $x \in X\}$ is the set of vertices in Y adjacent to some vertex of X.

A ***complete matching*** from X to Y in $G = (X \cup Y, E)$ is a matching M in which each vertex of X is incident with an edge of M.

The ***directed two-terminal flow network*** G' associated with $G = (X \cup Y, E)$ is defined by adding new vertices s and t, as well as arcs (s, x) for each $x \in X$ and arcs (y, t) for each $y \in Y$. All other arcs (x, y) of G' correspond to edges (x, y) of G where $x \in X$ and $y \in Y$. Every arc of G' has capacity 1.

Facts:

1. *Hall's theorem*: $G = (X \cup Y, E)$ has a complete matching from X to Y if and only if $|\Gamma(S)| \geq |S|$ holds for every $S \subseteq X$. In words, a complete matching exists precisely when every set of vertices in X is adjacent to at least an equal number of vertices in Y. (Philip Hall, 1904–1982.)

2. *König's theorem*: For a bipartite network G, the maximum size of a matching in G equals the minimum size of a vertex cover for G. (Dénes König, 1884–1944.)

3. *Sufficient condition for a complete matching*: Suppose there exists some k such that $deg(x) \geq k \geq deg(y)$ holds in $G = (X \cup Y, E)$ for all $x \in X$ and $y \in Y$. Then G has a complete matching from X to Y.

4. There is a one-to-one correspondence between matchings of size k in G and integral flows (§10.4.1) of value k in the associated two-terminal flow network G'.

5. A maximum flow in G', and thereby a maximum size matching of G, can be found in $O(m\sqrt{n})$ time.

6. Suppose that costs are added to the two-terminal flow network G', using $c_{ij} = 0$ if $i = s$ or $j = t$, and $c_{ij} = -w_{ij}$ otherwise. By starting with the flow (§10.5.1) $x = 0$, the successive shortest path algorithm (§10.5.2) can be applied to G' to produce a minimum cost flow. This will identify (via Fact 4) a matching with maximum weight.

7. *Bipartite matching algorithm*: This method (Algorithm 1), which is based on Fact 9 of §10.2.1, produces a maximum size matching of the bipartite network $G = (X \cup Y, E)$. Each iteration involves a modified breadth-first search of G (see §9.2.1), starting with the free vertices in the set X. All vertices of G are structured into levels that alternate between free and matched edges.

```
Algorithm 1: Bipartite matching algorithm.
 input: undirected bipartite network $G = (X \cup Y, E)$
 output: maximum size matching $M$
 $M := \emptyset$
 while true
   let $S_1$ consist of all free vertices of $X$
   mark all vertices of $S_1$ as seen, the remaining vertices as unseen
   while there are unseen vertices of $G$
     $S_2 := \{y \mid (x, y) \in E,\ x \in S_1,\ y \text{ unseen}\}$
     if some $y \in S_2$ is free then
       an augmenting path $P$ to $y$ has been found
       mark all remaining vertices of $G$ as seen
     else mark all vertices of $S_2$ as seen
       $S_1 := \{x \mid (y, x) \in M,\ y \in S_2,\ x \text{ unseen}\}$
       mark all vertices of $S_1$ as seen
   if an augmenting path $P$ has been found then $M := M \Delta P$
   else terminate with matching $M$
```

8. Algorithm 1 can be implemented to run in $O(nm)$ time.

9. *Bipartite weighted matching algorithm*: This method (Algorithm 2), which is based on Fact 13 of §10.2.1, produces a maximum weight matching of $G = (X \cup Y, E)$. Each iteration develops a longest path tree in G, rooted at the set of free vertices in X. The tentative largest weight of a path from a free vertex in X to vertex j is maintained in the label $d(j)$.

```
Algorithm 2: Bipartite weighted matching algorithm.
 input: undirected bipartite network $G = (X \cup Y, E)$, weights $w_e$
 output: maximum weight matching $M$
 $M := \emptyset$
 while true
   let $S_1$ consist of all free vertices of $X$
   $d(j) := 0$ for $j \in S_1$, $d(j) := -\infty$ otherwise
   while $S_1 \neq \emptyset$
     $S_2 := \emptyset$
     for $(x, y) \in E - M$ with $x \in S_1$
       if $d(x) + w_{xy} > d(y)$ then
         $d(y) := d(x) + w_{xy}$, $S_2 := S_2 \cup \{y\}$
     $S_1 := \emptyset$
     for $(y, x) \in M$ with $y \in S_2$
       if $d(y) - w_{yx} > d(x)$ then
         $d(x) := d(y) - w_{yx}$, $S_1 := S_1 \cup \{x\}$
   let $y$ be a free vertex with maximum label $d(y)$
   let $P$ be the associated augmenting path to $y$
```

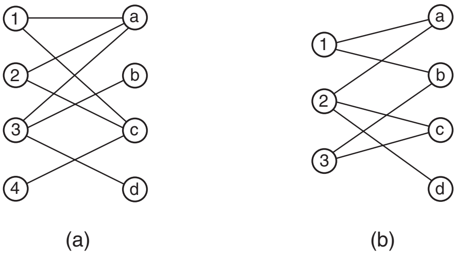
```
    if $d(y) > 0$ then $M := M\Delta P$
    else terminate with matching $M$
```

10. Algorithm 2 can be implemented to run in $O(nm)$ time.

Examples:

1. *Drug testing*: A drug company wishes to test n antibiotics using n volunteer patients. Some of the patients have known allergic reactions to certain of these antibiotics. To determine whether there is a feasible assignment of the n different antibiotics to n different patients, construct the bipartite network $G = (X \cup Y, E)$, where X is the set of antibiotics and Y is the set of patients. An edge $(i, j) \in E$ exists when patient j is not allergic to antibiotic i. A complete matching of G is then sought.

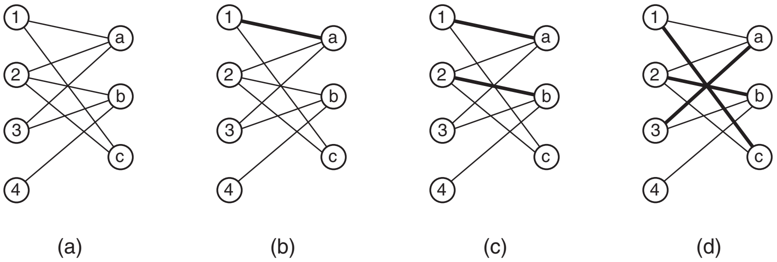
2. Part (a) of the following figure shows a bipartite graph G with $X = \{1, 2, 3, 4\}$ and $Y = \{a, b, c, d\}$.



Using Fact 1, there cannot be a complete matching from X to Y: if $S = \{1, 2, 4\}$ then $\Gamma(S) = \{a, c\}$ and $|\Gamma(S)| < |S|$. There is, however, a matching of size 3: for example, $\{(1, a), (3, b), (4, c)\}$. This matching has maximum size, since by Fact 2 there is a vertex cover $\{3, a, c\}$ of size 3.

3. Part (b) of the figure in Example 2 shows a bipartite graph G with $X = \{1, 2, 3\}$ and $Y = \{a, b, c, d\}$. Since $\deg(x) \geq 2 \geq \deg(y)$ holds for all $x \in X$ and $y \in Y$, there must exist a complete matching from X to Y. One such complete matching is given by $\{(1, a), (2, c), (3, b)\}$.

4. Algorithm 1 can be used to find a maximum size matching in the bipartite graph shown in part (a) of the following figure.



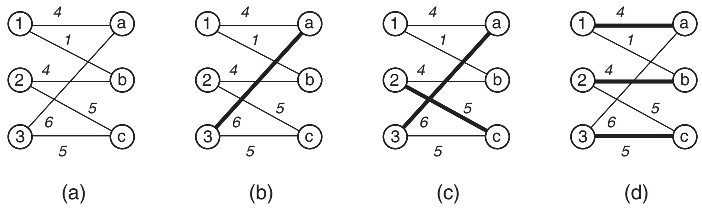
Relative to the initial empty matching, all vertices of X are free so $S_1 = \{1, 2, 3, 4\}$, giving $S_2 = \{a, b, c\}$. In particular, vertex $a \in S_2$ is free and an augmenting path to a is $P = \{(1, a)\}$. The resulting matching is $M = \{(1, a)\}$, shown in part (b) of the figure.

The second iteration of Algorithm 1 starts with $S_1 = \{2, 3, 4\}$, giving $S_2 = \{a, b, c\}$. An augmenting path to the free vertex b is $P = \{(2, b)\}$, resulting in $M = \{(1, a), (2, b)\}$; see part (c) of the figure.

At the next iteration, $S_1 = \{3,4\}$ and $S_2 = \{a,b\}$. Since both vertices of S_2 are now matched, the algorithm continues with $S_1 = \{1,2\}$ and $S_2 = \{c\}$. Since $c \in S_2$ is free, with augmenting path $P = \{(3,a),(a,1),(1,c)\}$, the new matching produced is $M = \{(1,c),(2,b),(3,a)\}$; see part (d) of the figure.

The fourth iteration produces $S_1 = \{4\}$, $S_2 = \{b\}$; $S_1 = \{2\}$, $S_2 = \{a,c\}$; and finally $S_1 = \{1,3\}$, $S_2 = \emptyset$. No further augmenting paths are found, and the algorithm terminates with the maximum size matching $M = \{(1,c),(2,b),(3,a)\}$.

5. Algorithm 2 can be used to find a maximum weight matching in the bipartite network shown in part (a) of the following figure.



(a) (b) (c) (d)

Relative to the initial empty matching, all vertices of X are free so $S_1 = \{1,2,3\}$, with $d(1) = d(2) = d(3) = 0$. The labels on vertices a,b,c are updated to $d(a) = 6$, $d(b) = 4$, $d(c) = 5$, giving $S_2 = \{a,b,c\}$. Since $M = \emptyset$ no further updates occur. The free vertex a has maximum label, and the associated path $P_1 = \{(3,a)\}$ has $wt(P_1) = 6$. The resulting matching $M = \{(3,a)\}$ is shown in part (b) of the figure; it represents the largest weight matching of size 1, with $wt(M) = 6$.

The second iteration starts with $S_1 = \{1,2\}$. The current labels on vertices a,b,c are then updated to $d(a) = 4$, $d(b) = 4$, $d(c) = 5$, so $S_2 = \{a,b,c\}$. Using the matched edge $(a,3)$, vertex 3 has its label updated to $d(3) = -2$ and $S_1 = \{3\}$. No further updates occur, and free vertex c with maximum label $d(c) = 5$ is selected. This label corresponds to the augmenting path $P_2 = \{(2,c)\}$, with $wt(P_2) = 5$. The new matching is $M = \{(2,c),(3,a)\}$, with $wt(M) = 11$; see part (c) of the figure.

At the third iteration, $S_1 = \{1\}$ and vertices a,b receive updated labels $d(a) = 4$, $d(b) = 1$. Subsequent updates produce $d(3) = -2$, $d(c) = 3$, $d(2) = -2$, $d(b) = 2$.

Finally, the free vertex b is selected with $d(b) = 2$, corresponding to the augmenting path $P_3 = \{(1,a),(a,3),(3,c),(c,2),(2,b)\}$ with $wt(P_3) = 2$. This produces the maximum weight matching $M = \{(1,a),(2,b),(3,c)\}$, with $wt(M) = 13$; see part (d) of the figure. As predicted by Fact 12 of §10.2.1, the weights of the augmenting paths are nonincreasing: $wt(P_1) \geq wt(P_2) \geq wt(P_3)$.

10.2.3 MATCHINGS IN NONBIPARTITE NETWORKS

This section covers matchings in more general (nonbipartite) networks. Algorithms for constructing maximum size and maximum weight matchings are considerably more intricate than for bipartite networks. The important new concept is that of a "blossom" in a network.

Definitions:

Suppose P is an alternating path from a free vertex s in network $G = (V,E)$. Then a vertex v on P is ***even*** (***outer***) if the subpath P_{sv} of P joining s to v has even length. Vertex v on P is ***odd*** (***inner***) if P_{sv} has odd length.

Suppose P is an alternating path from a free vertex s to an even vertex v and edge $(v, w) \in E$ joins v to another even vertex w on P. Then $P \cup \{(v, w)\}$ contains a unique cycle, called a ***blossom***.

A ***shrunken blossom*** results when a blossom B is collapsed into a single vertex b, whereby every edge (x, y) with $x \notin B$ and $y \in B$ is transformed into the edge (x, b). The reverse of this process gives an ***expanded blossom***.

Facts:

1. Every blossom B has odd length $2k + 1$ and contains k matched edges, for some $k \geq 1$.

2. A bipartite network contains no blossoms.

3. *Edmonds' theorem*: Suppose network G^B is formed from G by collapsing blossom B. Then G^B contains an augmenting path if and only if G does. (J. Edmonds, born 1965.)

4. *General matching algorithm*: This method (Algorithm 3), based on Fact 9 of §10.2.1, produces a maximum size matching of G. At each iteration, a forest of trees is grown, rooted at the free vertices of G, to find an augmenting path. As encountered, blossoms B are shrunk, with the search continued in the resulting network G^B.

Algorithm 3: **General matching algorithm.**

```
input: undirected network $G = (V, E)$
output: maximum size matching $M$
$M := \emptyset$
{Start iteration}
mark all free vertices as even
mark all matched vertices as unreached
mark all free edges as unexamined
while there are unexamined edges $(v, w)$ and no augmenting path is found
  mark $(v, w)$ as examined
  {Case 1}
  if $v$ is even and $w$ is unreached then
    mark $w$ as odd and its mate $z$ as even
    extend the forest by $(v, w)$ and the matched edge $(w, z)$
  {Case 2}
  if $v, w$ are even and they belong to different subtrees then
    an augmenting path has been found
  {Case 3}
  if $v, w$ are even and they belong to the same subtree then
    a blossom $B$ has been found
    shrink $B$ to an even vertex $b$
if an augmenting path $P$ has been found then
  $M := M \Delta P$
  go to {Start iteration}
else terminate with matching $M$
```

5. Algorithm 3 was initially proposed by Edmonds [Ed65a] with a time bound of $O(n^4)$.

6. An improved implementation of Algorithm 3 runs in $O(nm)$ time.

7. There are other algorithms for maximum size matchings in nonbipartite networks:

- an algorithm of Gabow [Ga76], which runs in time $O(n^3)$;
- an algorithm of Micali and Vazirani [MiVa80], which runs in $O(m\sqrt{n})$ time.

Computer codes for these algorithms can be found at

- `ftp://dimacs.rutgers.edu/pub/netflow/matching/`

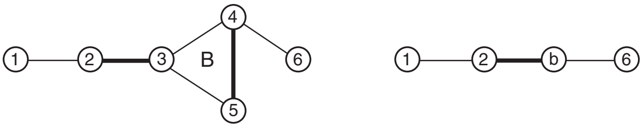
8. *General weighted matching algorithms*: More complicated algorithms are required for solving weighted matching problems. The first such algorithm, also involving blossoms, was developed by Edmonds [Ed65b] and has a time bound of $O(n^4)$.

9. Improved algorithms exist for the weighted matching problem, with running times $O(n^3)$, $O(nm \log n)$, and $O(nm + n^2 \log n)$ respectively. Computer code for the first of these algorithms can be found at

- `ftp://dimacs.rutgers.edu/pub/netflow/matching/`

Examples:

1. In part (a) of the following figure, $P = \{(1,2),(2,3),(3,4),(4,5)\}$ is an alternating but not augmenting path, relative to the matching $M = \{(2,3),(4,5)\}$.



(a) (b)

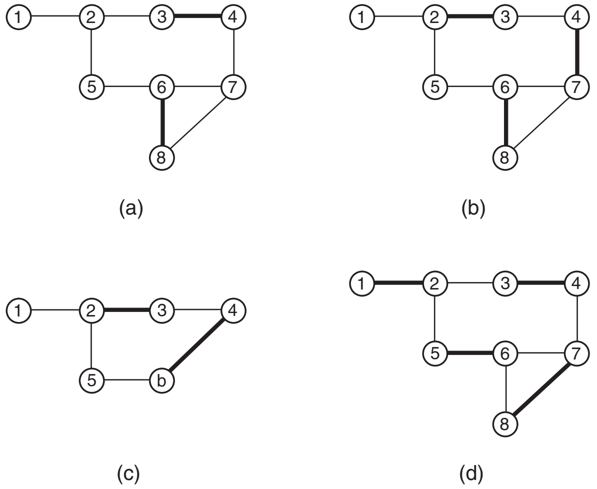
Relative to this path, vertices 1, 3, 5 are even while vertices 2, 4 are odd. Since $(3,5)$ is an edge joining two even vertices on P, the blossom $B = \{(3,4),(4,5),(5,3)\}$ is formed. On the other hand, $Q = \{(1,2),(2,3),(3,5),(5,4),(4,6)\}$ is an augmenting path relative to M so that $M \Delta Q = \{(1,2),(3,5),(4,6)\}$ is a matching of larger size—in fact a matching of maximum size. Notice that relative to path Q, vertices 1, 3, 4 are even while vertices 2, 5, 6 are odd.

2. Shrinking the blossom B relative to path P in part (a) of the figure of Example 1 produces the network G^B shown in part (b) of that figure; note that vertices $1, b$ are even while vertices $2, 6$ are odd. The path $P^B = \{(1,2),(2,b),(b,6)\}$ is now augmenting in G^B. By expanding P^B so that $(2,3)$ remains matched and $(4,6)$ remains free, the augmenting path $Q = \{(1,2),(2,3),(3,5),(5,4), (4,6)\}$ in G is obtained.

3. Algorithm 3 is applied to the nonbipartite network shown in part (a) of the following figure. Suppose the matching $M = \{(3,4),(6,8)\}$ of size 2 is already available.

Iteration 1: The free vertices 1, 2, 5, 7 are marked as even, and the matched vertices 3, 4, 6, 8 are marked as unreached. The initial forest consists of the isolated vertices 1, 2, 5, 7.

- If the free edge $(2,3)$ is examined, then Case 1 applies, so vertex 3 is marked odd and vertex 4 even; the free edge $(2,3)$ and the matched edge $(3,4)$ are added to the forest.
- If the free edge $(4,7)$ is examined, then Case 2 applies, and the augmenting path $P = \{(2,3),(3,4),(4,7)\}$ is found. Using P the new matching $M = \{(2,3),(4,7),(6,8)\}$ of size 3 is obtained; see part (b) of the figure.



Iteration 2: The forest is initialized with the free (even) vertices 1, 5.

- If the free edge $(1, 2)$ is examined, then Case 1 applies, so vertex 2 is marked odd and vertex 3 even; edges $(1, 2)$ and $(2, 3)$ are added to the forest.
- Examining in turn the free edges $(3, 4)$ and $(7, 6)$ makes 4, 6 odd vertices and 7, 8 even. Edges $(3, 4), (4, 7), (7, 6), (6, 8)$ are then added to the subtree rooted at 1.
- If edge $(7, 8)$ is examined, Case 3 applies so the blossom $B = \{(7, 6), (6, 8), (8, 7)\}$ is detected and shrunk to the even vertex b; part (c) of the figure shows the resulting G^B. The current subtree rooted at 1 now becomes $\{(1, 2), (2, 3), (3, 4), (4, b)\}$.
- If the free edge $(b, 5)$ is examined, then Case 2 applies and the augmenting path $\{(1, 2), (2, 3), (3, 4), (4, b), (b, 5)\}$ is found in G^B. The corresponding augmenting path in G is $P = \{(1, 2), (2, 3), (3, 4), (4, 7), (7, 8), (8, 6), (6, 5)\}$. Forming $M \Delta P$ produces the new matching $\{(1, 2), (3, 4), (7, 8), (5, 6)\}$, a maximum size matching; see part (d) of the figure.

10.2.4 STABLE MATCHINGS

The stable matching problem, formulated on a bipartite network $G = (X \cup Y, E)$, incorporates preferences of the items/individuals in X for those in Y and likewise the preferences of the items/individuals in Y for those in X. In a stable matching there is no incentive for an unmatched pair (x, y) to both find it desirable to switch their existing mates for one another. This is an important model for assignment problems with preferences (e.g., the assignment of medical residents to hospitals, students to schools, and organ donors to patients).

Definitions:

Let G be a ***complete bipartite graph*** (§8.1.3) on the vertex set $X \cup Y$, where X and Y are disjoint sets with $|X| = |Y| = n$ and (x, y) is an edge for every $x \in X$ and $y \in Y$. For each $x \in X$, let $\succ_{\mathbf{x}}$ be an ordering of the elements of Y; for each $y \in Y$, let $\succ_{\mathbf{y}}$ be an ordering of the elements of X.

Suppose M is a perfect matching in $G = (X \cup Y, E)$. Then w is the ***mate*** $M(v)$ of $v \in X \cup Y$ if $(v, w) \in M$. The pair $(x, y) \in X \times Y$ is a ***blocking pair*** or ***instability*** if

$(x, y) \notin M$, yet $y \succ_x M(x)$ and $x \succ_y M(y)$. In other words, each of x and y prefer one another to their current mate.

A perfect matching M of G is ***stable*** if there are no blocking pairs relative to M.

Individuals x and y are ***stable partners*** if $(x, y) \in M$ for *some* stable matching M.

Facts:

1. A stable matching in $G = (X \cup Y, E)$ always exists and can be found by using Algorithm 4, called the Gale-Shapley algorithm [GaSh62].

Algorithm 4: **Gale-Shapley algorithm.**

```
input: complete bipartite graph $G$ on $X \cup Y$, with $|X| = |Y|$
output: stable matching $M$ of $G$
let all $x \in X$ and $y \in Y$ be free
while there is some free $x$
  select such an $x$
  let $y$ be the greatest element of $Y$ (according to $\succ_x$) that has not rejected $x$
    if $y$ is free, tentatively match $y$ with $x$
      add $(x, y)$ to $M$
    else
      if $x \succ_y M(y)$ then
        make $M(y)$ free and tentatively match $y$ with $x$
      else
        permanently record that $y$ has now rejected $x$
```

2. Each iteration of Algorithm 4 involves a free vertex x "proposing" to its most-preferred choice $y \in Y$ that has not yet rejected it. Once a proposal has been rejected, it is never reconsidered. However, the individuals in Y can always "trade up" if a proposal is made from a more preferred partner.

3. Surprisingly, Algorithm 4 always terminates and will do so with a stable matching. Moreover, the outcome is the same regardless of the order in which the free vertices in X are processed.

4. Algorithm 4 terminates after at most n^2 iterations and can be implemented to run in $O(n^2)$ time.

5. Algorithm 4 finds the best stable matching for X. That is, every $x \in X$ is matched with its *most preferred* stable partner.

6. Algorithm 4 finds the worst stable matching for Y. That is, every $y \in Y$ is matched with its *least preferred* stable partner.

7. By reversing the roles of X and Y in Algorithm 4, we obtain a best stable matching for Y.

8. While formulated for a complete bipartite graph G with $|X| = |Y|$, the stable matching problem can be generalized to an arbitrary bipartite graph. In this case, edges of G indicate acceptable partners. Stability of M now means that no x, y that are not matched with each other prefer one another to their current partners $M(x), M(y)$. A stable matching may no longer be perfect.

9. A number of applications (e.g., assigning students to schools) require the possibility of multiple partners. For example, in the school assignment context, each student would be assigned to a single school, but schools can admit many students. This generalization allows each $y \in Y$ to have an integer quota $q_y \geq 1$. In fact, this situation can be reduced to a standard matching problem by making q_y copies of y, and by letting each copy have the same preference ordering over X as the original y.

10. Since the stable matching produced by the Gale-Shapley algorithm greatly advantages the individuals in X and greatly disadvantages the individuals in Y (see Facts 5–6), work has proceeded to find more equitable stable matchings [GuIr89].

11. The 2012 Nobel Prize in Economics was awarded to Lloyd S. Shapley and Alvin E. Roth for their pioneering work on stable matchings and applications to important societal problems.

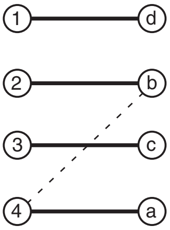
Examples:

1. The following table shows the preferences (in descending order) of the individuals in $X = \{1, 2, 3, 4\}$ for those in $Y = \{a, b, c, d\}$ and likewise the preferences of the individuals in Y for those in X.

1	d	b	c	a
2	a	d	b	c
3	a	c	b	d
4	c	b	d	a

a	1	3	2	4
b	4	2	1	3
c	2	1	3	4
d	4	2	1	3

The matching $\{(1, d), (2, b), (3, c), (4, a)\}$ is shown in bold in the following figure. This matching is not stable since $(4, b)$ (shown as dashed) is a blocking pair for the matching. Namely, $b \succ_4 a$ and $4 \succ_b 2$.



2. The matching $\{(1, b), (2, d), (3, a), (4, c)\}$ is stable. To verify this, observe that 3 and 4 are matched with their top choice, so they cannot be part of a blocking pair. Suppose 1 was matched with a higher choice than b, namely d; however, d prefers the current mate 2 to 1 so $(1, d)$ is not a blocking pair. Similarly, the only possible blocking pair involving 2 is $(2, a)$, but a prefers the current mate 3 to 2.

3. The matching $\{(1, c), (2, d), (3, a), (4, b)\}$ is also stable. This is the only other stable matching for the given set of preferences.

4. Applying Algorithm 4 to the instance in Example 1 results in the following. First, 1 proposes to d and is tentatively accepted; 2 proposes to a and is tentatively accepted. Next, 3 proposes to a; since 3 is more favored by a than its current partner 2, a accepts the proposal and rejects 2. Then 4 proposes to c and is tentatively accepted. The current matching is now $\{(1, d), (3, a), (4, c)\}$. Now 2 proposes to d, the most-preferred of the remaining candidates, who accepts the proposal and rejects 1. Then 1 proposes to b, the most-preferred of the remaining candidates, who accepts the proposal.

At this point no member of X is free and so the algorithm terminates with the matching $\{(1,b),(2,d),(3,a),(4,c)\}$. This is the stable matching identified in Example 2. Notice that this matching pairs 3 and 4 with their first choices, while 1 and 2 are paired with their second choices.

5. As indicated in Example 3, the only other stable matching for the given preferences is the matching $\{(1,c),(2,d),(3,a),(4,b)\}$. Notice that this matching pairs 3 with its first choice, 2 and 4 with their second choice, and 1 with its third choice. This verifies Fact 5, showing that the stable matching found by Algorithm 4 matches each member of X with its most preferred stable partner.

6. By reversing the roles of X and Y in Algorithm 4, we obtain the second stable matching $\{(1,c),(2,d),(3,a),(4,b)\}$. This matching, which pairs b with its first choice, and a,c,d with their second choice, is the best stable matching for Y. (See Fact 6.)

10.2.5 APPLICATIONS

Matching problems, in both bipartite and nonbipartite networks, are useful models in a number of applied areas. This section presents some representative applications of matchings.

Applications:

1. *Linear assignment problem*: There are n applicants to be assigned to n jobs, with each job being filled with exactly one applicant. The weight w_{ij} measures the suitability of applicant i for job j. Finding a valid assignment with the best overall weight is a weighted matching problem on the bipartite network $G=(X\cup Y,E)$, where X is the set of applicants and Y is the set of jobs.

2. *Personnel assignment*: Pairs of pilots are to be assigned to a fleet of aircraft serving international routes. Pilots i and j are considered compatible if they are fluent in a common language and have comparable flight training. Form the network G whose vertices represent the pilots and with edges placed between compatible pairs of pilots. The problem of flying the largest number of aircraft with compatible pilots can then be solved as a maximum size matching problem on G.

3. Other examples of Application 2 occur in assigning police officers sharing beats, matching pairs of compatible roommates, and assigning pairs of employees with complementary skills to specific projects.

4. *Pruned chessboards*: Several squares ($2k$ in all) are removed from an $n\times n$ chessboard, yielding the pruned chessboard $\mathcal{P}$. Is it then possible to cover the squares of $\mathcal{P}$ using nonoverlapping dominoes, with no squares left uncovered? This can be formulated as a matching problem on the bipartite network $G=(R\cup B,E)$, where R is the set of red squares and B is the set of black squares in $\mathcal{P}$. An edge joins $r\in R$ to $b\in B$ if squares r and b share a common side. Each set of nonoverlapping dominoes on $\mathcal{P}$ corresponds to a matching in G.

All squares of $\mathcal{P}$ can be covered using nonoverlapping dominoes if and only if the maximum size matching in G has size $\frac{n^2}{2}-k$. More generally, a maximum size matching in G explicitly provides a way to cover the maximum number of squares of $\mathcal{P}$ using nonoverlapping dominoes.

5. *Target tracking*: The movements of n objects (such as submarines or missiles) are to be followed over time. The locations of the set of objects are known at two distinct times, though without identification of the individual objects. Suppose $X = \{x_1, x_2, \ldots, x_n\}$ and $Y = \{y_1, y_2, \ldots, y_n\}$ represent the spatial coordinates of the objects detected at times t and $t + \Delta t$. If Δt is sufficiently small, then the Euclidean distance between a given object's position at these two times should be relatively small. To aid in identifying the objects (as well as their velocities and directions of travel), a pairing between set X and set Y is desired that minimizes the sum of Euclidean distances.

This can be formulated as a maximum weight matching problem on the complete bipartite network $G = (X \cup Y, E)$, where the edge (i, j) indicates pairing position x_i with position y_j. The weight of this edge is the negative of the Euclidean distance between x_i and y_j. A maximum weight matching of size n in G then provides an optimal (minimum distance) pairing of all observations at the two times t and $t + \Delta t$.

6. *Crew scheduling*: Bus drivers are hired to work two four-hour shifts each day. Union rules require a certain minimum amount of time between the shifts that a driver can work. There are also costs associated with getting the driver between the ending location of the first shift and the starting location of the second shift.

The problem of optimally combining pairs of shifts that satisfy union regulations and incur minimum total cost can be formulated as a maximum weight matching problem. Namely, define the network G with vertices representing each shift that must be covered and edges between pairs of compatible shifts (satisfying union regulations). The weight of edge (i, j) is the negative of the cost of assigning a single driver to shifts i and j. It is convenient also to add edges (i, i) to G to represent the possibility of needing a part-time driver to cover a single shift; edge (i, i) is given a sufficiently large negative weight to discourage single-shift assignments unless absolutely necessary. A maximum weight matching in the network G then provides a minimum cost pairing of shifts for the bus drivers.

7. *Snowplowing streets*: The streets of an area of a city are to be plowed by a single snowplow. Let G be the network representing the street system of the city, with vertices representing street intersections and edges representing streets. Associated with each street (i, j) is its length c_{ij}.

If all vertices of G have even degree, then G is an Eulerian graph (§8.4.3) and a circuit that traverses each edge (street) exactly once can be found using the algorithms in §8.4.3. Otherwise, a closed walk of G that covers each street at least once is needed, and one with minimum total length $\sum c_{ij}$ is desired. Let N be the set of vertices of G having odd degree; by Fact 4 of §8.1.1, $|N|$ is an even integer $2k$. Form the complete network $H = (N, E)$ in which the weight of edge (i, j) is the negative of the shortest path distance (§10.3.1) between vertices i and j in G. Determine a maximum weight (perfect) matching M of size k in H. For each (i, j) in M, add the edges of the shortest path between i and j to the network G, forming the network G'. Every vertex of G' now has even degree, and an Euler circuit of G' provides a minimum cost traversal of the city streets.

This problem is known as the (undirected) *Chinese postman problem*. A directed version of the problem is discussed in §10.5.3, Application 3.

8. *Sparse matrices*: In solving large sparse systems of linear equations, it is advantageous to first reorder the rows and columns of the given $n \times n$ coefficient matrix A. Specifically, it is desired to place as many nonzero entries on the diagonal of the permuted matrix [Du81]. This can be viewed as a maximum size matching problem on a bipartite graph $G = (X \cup Y, E)$ associated with the coefficient matrix A. Here X contains the n row indices, Y contains the n column indices, and edge (i, j) exists whenever $a_{ij} \neq 0$.

9. *Stable matchings*: A celebrated application of the stable matching model can be found in the National Resident Matching Program (NRMP), which assigns graduating medical students (residents) to hospitals. The algorithm developed for this centralized matching program (in use from 1952) was very similar in operation to the Gale-Shapley algorithm and produced hospital-optimal stable matchings. Roth and Peranson [RoPe99] helped to redesign the NRMP matching algorithm, now a variant of the resident-optimal Gale-Shapley algorithm.

10.3 SHORTEST PATHS

The shortest path problem requires finding paths of minimum cost (or length) from a specified source vertex to every other vertex in a directed network. Shortest path problems lie at the heart of network flows (§10.4–§10.5). They are important both to researchers and to practitioners because

- they arise frequently in application settings where material is to be sent between specified points as quickly, as cheaply, or as reliably as possible;
- they arise as subproblems when solving many combinatorial and network optimization problems;
- they can be solved very efficiently.

10.3.1 BASIC CONCEPTS

Definitions:

A ***directed network*** is a weighted graph $G = (V, E)$, where V is the set of vertices and E is the set of arcs (directed edges). Each arc $(i, j) \in E$ has an associated ***cost*** (or ***weight***, ***length***) c_{ij}. It is possible that certain of the c_{ij} are negative. Let $n = |V|$ and $m = |E|$.

The ***adjacency set*** $A(i)$ for vertex i is the set of all arcs incident from i, written $A(i) = \{(i,j) \mid (i,j) \in E\}$.

A directed path (§8.3.2) P has ***length*** $\Sigma_{(i,j)\in P}\, c_{ij}$.

A directed cycle (§8.3.2) W for which $\Sigma_{(i,j)\in W}\, c_{ij} < 0$ is called a ***negative cycle***.

A ***shortest path*** from vertex s to vertex j is a directed s-j path having minimum length.

A ***directed out-tree*** is a tree rooted at vertex s in which all arcs are directed away from the root s.

A ***shortest path tree*** is an out-tree T^* rooted at vertex s with the property that the directed path in T^* from s to any other vertex j is a shortest s-j path.

A vector $d(\cdot)$ is called a vector of ***distance labels*** if for every vertex $j \in V$, $d(j)$ is the length of some directed path from the source vertex s to vertex j, with $d(s) = 0$. If these labels are the lengths of shortest s-j paths, they are called ***shortest path distances***.

The directed path $P = [i_0, i_1, \ldots, i_r]$ from vertex i_0 to vertex i_r can be represented using ***predecessor indices***: $\mathit{pred}(i_1) = i_0, \mathit{pred}(i_2) = i_1, \ldots, \mathit{pred}(i_r) = i_{r-1}$.

Facts:

1. Shortest paths are useful in a wide variety of applications, such as in efficient routing of messages and distribution of goods, developing optimal investment strategies, scheduling personnel, and approximating piecewise linear functions (see §10.3.5).

2. If $P = [s, i_1, \ldots, i_r]$ is a shortest path from s to i_r then $Q = [s, i_1, \ldots, i_k]$ is a shortest path from s to i_k for each $1 \le k < r$.

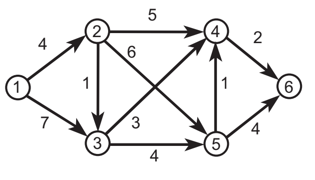
3. *Shortest path optimality conditions*: The vector $d(\cdot)$ of distance labels represents shortest path distances if and only if $d(j) \le d(i) + c_{ij}$ for all $(i,j) \in E$.

4. If the network contains a negative cycle accessible from vertex s, then distance labels satisfying the conditions in Fact 3 do not exist.

5. If the network does not contain any negative cycle, then (unique) distance labels satisfying the conditions in Fact 3 always exist. Furthermore, there is a shortest path tree T^* realizing these shortest path distances.

Examples:

1. In the directed network of the following figure, arc costs are shown along each arc. Part (b) lists the nine paths from vertex 1 to vertex 6, together with their lengths. Path P_4, with length 10, is the (unique) shortest path joining these two vertices. This path can be represented using the predecessor indices: $\mathit{pred}(6) = 4$, $\mathit{pred}(4) = 3$, $\mathit{pred}(3) = 2$, $\mathit{pred}(2) = 1$. By Fact 2, the subpath $Q = [1, 2, 3, 4]$ of P_4 is a shortest path from vertex 1 to vertex 4.



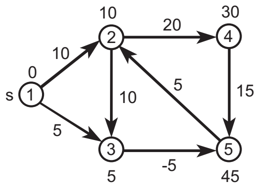
(a)

	Path	Length
P_1	[1, 2, 4, 6]	11
P_2	[1, 2, 5, 6]	14
P_3	[1, 2, 5, 4, 6]	13
P_4	[1, 2, 3, 4, 6]	10
P_5	[1, 2, 3, 5, 6]	13
P_6	[1, 2, 3, 5, 4, 6]	12
P_7	[1, 3, 4, 6]	12
P_8	[1, 3, 5, 4, 6]	14
P_9	[1, 3, 5, 6]	15

(b)

2. In the directed network of the following figure, arc costs are shown along each arc and a set of distance labels is shown at each vertex. Part (b) gives paths from vertex $s = 1$ whose lengths equal the corresponding distance labels. These distance labels do not satisfy the optimality conditions of Fact 3 because for the arc $(3,5)$, $d(5) > d(3)+c_{35}$. The out-tree T in this figure defined by predecessor indices $pred(2) = 5$, $pred(3) = 1$, $pred(4) = 2, pred(5) = 3$ has distance labels $d = (0,5,5,25,0)$. It is a shortest path tree rooted at vertex 1 since the optimality conditions of Fact 3 are satisfied: namely

$$5 \le 0+10 \text{ for arc } (1,2), \quad 5 \le 5+10 \text{ for arc } (2,3), \quad 0 \le 25+15 \text{ for arc } (4,5).$$



(a)

j	d(j)	path
2	10	[1,2]
3	5	[1,3]
4	30	[1,2,4]
5	45	[1,2,4,5]

(b)

10.3.2 ALGORITHMS FOR SINGLE-SOURCE SHORTEST PATHS

This subsection discusses algorithms for finding shortest path trees from a given source vertex s in a directed network G with n vertices and m arcs.

Facts:

1. *Label-correcting algorithm*: A general label-correcting algorithm (Algorithm 1) is based on the shortest path optimality conditions (§10.3.1, Fact 3) and is a very popular algorithm to solve shortest path problems with arbitrary arc costs (L. R. Ford, 1956 and R. E. Bellman, 1958).

```
Algorithm 1: Label-correcting algorithm.
  input: directed network $G$, source vertex $s$
  output: shortest path tree $T^*$ rooted at $s$
  $d(s) := 0$
  $pred(s) := 0$
  $d(j) := \infty$ for all $j \in V - \{s\}$
  LIST := $\{s\}$
  while LIST $\neq \emptyset$
    remove a vertex $i$ from LIST
    for each $(i,j) \in A(i)$
      if $d(j) > d(i) + c_{ij}$ then
        $d(j) := d(i) + c_{ij}$
        $pred(j) := i$
        if $j \notin$ LIST then add $j$ to LIST
```

2. Algorithm 1 maintains a list, LIST, of vertices with the property that if an arc (i,j) violates the optimality condition, then LIST must contain vertex i. If LIST is empty, then the current distance labels are optimal. Otherwise some vertex i is removed from LIST and the arcs of $A(i)$ are scanned. If an arc $(i,j) \in A(i)$ violates the optimality condition, then $d(j)$ is updated appropriately.

3. When Algorithm 1 terminates, the nonzero predecessor indices define a shortest path tree T^* rooted at the source vertex: namely, $T^* = \{(pred(i), i) \mid i \in V - \{s\}\}$.

4. *Convergence*: In Algorithm 1, vertices in LIST can be selected in any order and the algorithm still converges finitely. If all arc costs are integers whose magnitudes are bounded by a constant C, then the algorithm performs $O(n^2C)$ iterations and can be implemented to run in $O(nmC)$ time, regardless of the order in which vertices from LIST are selected.

5. *Queue implementation*: Suppose in Algorithm 1 that LIST is maintained as a queue (§18.1.2); that is, vertices in LIST are examined in a first-in-first-out (FIFO) order. This specific implementation examines no vertex more than $n-1$ times and runs in $O(nm)$ time. This is the best strongly polynomial-time algorithm to solve the shortest path problem with arbitrary arc costs.

6. *Deque implementation*: Suppose in Algorithm 1 that LIST is maintained as a deque or two-way list (§18.1.2). Specifically, vertices are removed from the front of the deque, but vertices are added either at the front or at the rear. If the vertex has been in LIST earlier, the algorithm adds it to the front; otherwise, it adds the vertex to the rear. Empirical studies have found that the deque implementation is one of the most efficient algorithms to solve the shortest path problem in practice even though it is not a polynomial-time algorithm.

7. *Negative cycle detection*: The queue implementation (Fact 5) of the label-correcting algorithm can be used to detect the presence of a negative cycle. To do so, record the number of times that the algorithm examines each vertex. If the algorithm examines a vertex more than $n-1$ times, there must exist a negative cycle. In this case, the subgraph formed by the arcs $(pred(i), i)$ will contain a negative cycle.

8. Goldberg [Go95] developed a scaling algorithm that determines a negative cost cycle in $O(\sqrt{n}m \log C)$ time. It is the fastest running time for a large range of values of C.

9. Cherkassky et al. [ChGoRa96], [ChEtal09] have carried out careful computational analyses of algorithms for single-source shortest path problems.

10. *Dijkstra's algorithm (1959)*: Dijkstra's algorithm (Algorithm 2) is a popular algorithm for solving shortest path problems with nonnegative arc costs (E. W. Dijkstra, 1930–2002).

Algorithm 2: **Dijkstra's algorithm.**

```
input: directed network $G$ with $c_{ij} \geq 0$, source vertex $s$
output: shortest path tree $T^*$ rooted at $s$
$d(s) := 0$
$pred(s) := 0$
$d(j) := \infty$ for all $j \in V - \{s\}$
LIST := $V$
while LIST $\neq \emptyset$
   {Vertex selection}
   let $i \in$ LIST be a vertex for which $d(i) = \min\{d(j) \mid j \in$ LIST$\}$
   remove vertex $i$ from LIST
```

```
{Distance update}
for each $(i, j) \in A(i)$
  if $d(j) > d(i) + c_{ij}$ then
    $d(j) := d(i) + c_{ij}$
    $pred(j) := i$
```

11. Algorithm 2 performs two steps repeatedly: *vertex selection* and *distance update*. The vertex selection step chooses a vertex i with smallest distance label in LIST for examination. The distance update step scans each arc $(i, j) \in A(i)$ and updates the distance label $d(j)$, if necessary, to restore the optimality condition for arc (i, j).

12. Whenever a vertex is selected for examination in Algorithm 2, its distance label is the shortest path distance from s; consequently, each vertex is examined only once.

13. Using a simple array or linked list representation of LIST, vertex selections take a total of $O(n^2)$ time and distance updates take a total of $O(m)$ time. This implementation of Algorithm 2 runs in $O(n^2)$ time.

14. By using more sophisticated data structures, the efficiency of Dijkstra's algorithm can be improved. Currently, two of the best implementations use

- Fibonacci heaps, giving $O(m + n \log n)$ running time [FrTa84];
- radix heaps, giving $O(m + n(\log C)^{1/2})$ running time [AhEtal90].
