        * | SET_SYN_AL | proc_nr | | delta |
11025
11026
        * _____
        * NEW_TIME, DELTA_CLICKS, and SECONDS_LEFT all refer to the same field in
11027
11028
        * the message, depending upon the message type.
11029
11030
        * Reply messages are of type OK, except in the case of a HARD_INT, to
        * which no reply is generated. For the GET_* messages the time is returned
11031
        * in the NEW_TIME field, and for the SET_ALARM and SET_SYN_AL the time
11032
        * in seconds remaining until the alarm is returned is returned in the same
11033
11034
        * field.
11035
        * When an alarm goes off, if the caller is a user process, a SIGALRM signal
11036
        * is sent to it. If it is a task, a function specified by the caller will
11037
11038
        * be invoked. This function may, for example, send a message, but only if
        * it is certain that the task will be blocked when the timer goes off. A
11039
        * synchronous alarm sends a message to the synchronous alarm task, which
11040
        * in turn can dispatch a message to another server. This is the only way
11041
        * to send an alarm to a server, since servers cannot use the function-call
11042
        * mechanism available to tasks and servers cannot receive signals.
11043

         * Many global global and static variables are accessed here. The safety
11389
         * of this must be justified. Most of them are not changed here:
11390
11391
                k_reenter:
                        This safely tells if the clock interrupt is nested.
11392
11393
                proc_ptr, bill_ptr:
                        These are used for accounting. It does not matter if proc.c
11394
         ×
                        is changing them, provided they are always valid pointers,
11395
                        since at worst the previous process would be billed.
         *
11396
                next_alarm, realtime, sched_ticks, bill_ptr, prev_ptr,
11397
                rdy_head[USER_Q]:
11398
                        These are tested to decide whether to call interrupt(). It
11399
                        does not matter if the test is sometimes (rarely) backwards
         ×
11400
                       due to a race, since this will only delay the high-level
11401
                       processing by one tick, or call the high level unnecessarily.
11402
11403
         * The variables which are changed require more care:
11404
                rp->user_time, rp->sys_time:
```

11405 These are protected by explicit locks in system.c. They are \* 11406 not properly protected in dmp.c (the increment here is not 11407 \* atomic) but that hardly matters. 11408 pending\_ticks: 11409 This is protected by explicit locks in clock.c. Don't 11410 update realtime directly, since there are too many 11411 references to it to guard conveniently. 11412 lost\_ticks: 11413 \* Clock ticks counted outside the clock task. \* 11414 sched\_ticks, prev\_ptr: ŵ 11415 Updating these competes with similar code in do\_clocktick(). 11416 No lock is necessary, because if bad things happen here 11417 (like sched\_ticks going negative), the code in do\_clocktick() 11418 \* will restore the variables to reasonable values, and an \* 11419 occasional missed or extra sched() is harmless. 11420 11421 \* Are these complications worth the trouble? Well, they make the system 15% 11422 \* faster on a SMHz 8088, and make task debugging much easier since there are 11423 \* no task switches on an inactive system. 11424 \*/ 11425 11426 register struct proc \*rp; 11427 register unsigned ticks; 11428 clock\_t now; 11429 11430 if (ps\_mca) { 11431 /\* Acknowledge the PS/2 clock interrupt. \*/ 11432 out\_byte(PORT\_B, in\_byte(PORT\_B) | CLOCK\_ACK\_BIT); 11433 } 11434 11435 /\* Update user and system accounting times. 11436 \* First charge the current process for user time. 11437 \* If the current process is not the billable process (usually because it 11438 \* is a task), charge the billable process for system time as well. 11439 \* Thus the unbillable tasks' user time is the billable users' system time. #/ 11440 if (k\_reenter != 0) 11441 rp = proc\_addr(HARDWARE); 11442 11443 else 11444 rp = proc\_ptr; 11445 ticks = lost\_ticks + 1; 11446 lost\_ticks = 0; 11447 rp->user\_time += ticks; if (rp != bill\_ptr && rp != proc\_addr(IDLE)) bill\_ptr->sys\_time += ticks; 11448 11449 11450 pending\_ticks += ticks; 11451 now = realtime + pending\_ticks; /\* possibly wake up TTY \*/ 11452 if (tty\_timeout <= now) tty\_wakeup(now);</pre> 11453 /\* possibly restart printer \*/ pr\_restart(); 11454 if (next\_alarm <= now || 11455 11456 sched\_ticks == 1 && 11457 bill\_ptr == prev\_ptr && 11458 rdy\_head[USER\_Q] != NIL\_PROC) { 11459 interrupt(CLOCK); 11460 return 1; /\* Reenable interrupts \*/ 11461 } 11462 11463 if (--sched\_ticks == 0) { 11464 /\* If bill\_ptr == prev\_ptr, no ready users so don't need sched(). \*/

src/kernel/tty.c /\* This file contains the terminal driver, both for the IBM console and regular 11700 \* ASCII terminals. It handles only the device-independent part of a TTY, the 11701 \* device dependent parts are in console.c, rs232.c, etc. This file contains 11702 \* two main entry points, tty\_task() and tty\_wakeup(), and several minor entry 11703 \* points for use by the device-dependent code. 11704 11705 \* The device-independent part accepts "keyboard" input from the device-11706 \* dependent part, performs input processing (special key interpretation), 11707 \* and sends the input to a process reading from the TTY. Output to a TTY 11708 \* is sent to the device-dependent code for output processing and "screen" 11709 \* display. Input processing is done by the device by calling 'in\_process' 11710 \* on the input characters, output processing may be done by the device itself 11711 \* or by calling 'out\_process'. The TTY takes care of input queuing, the 11712 \* device does the output queuing. If a device receives an external signal, 11713 \* like an interrupt, then it causes tty\_wakeup() to be run by the CLOCK task 11714 \* to, you guessed it, wake up the TTY to check if input or output can 11715 \* continue. 11716 11717 \* The valid messages and their parameters are: 11718 ÷ 11719 output has been completed or input has arrived ÷. HARD\_INT: 11720 \* a process wants to read from a terminal DEV\_READ: 11721 \* DEV\_WRITE: a process wants to write on a terminal 11722 \* DEV\_IOCTL: a process wants to change a terminal's parameters 11723 π. DEV\_OPEN: a tty line has been opened 11724 DEV\_CLOSE: × a tty line has been closed 11725 terminate a previous incomplete system call immediately \* CANCEL: 11726 \* 11727 TTY\_LINE PROC\_NR COUNT TTY\_SPEK TTY\_FLAGS ADDRESS \* m\_type 11728 - \* \_\_\_\_\_ 11729 \* | HARD\_INT | | | | | | 11730 11731 \* | DEV\_READ | minor dev | proc nr | count | 0\_NONBLOCK | buf ptr | 11732 11733 \* | DEV\_WRITE |minor dev| proc\_nr | count | | | buf ptr | 11734

13600
         /* Code and data for the IBM console driver.
13601
13602
         * The 6845 video controller used by the IBM PC shares its video memory with
         * the CPU somewhere in the 0xB0000 memory bank. To the 6845 this memory
13603
13604
         * consists of 16-bit words. Each word has a character code in the low byte
13605
         * and a so-called attribute byte in the high byte. The CPU directly modifies
13606
         * video memory to display characters, and sets two registers on the 6845 that
         * specify the video origin and the cursor position. The video origin is the
13607
         * place in video memory where the first character (upper left corner) can
13608
13609
         * be found. Moving the origin is a fast way to scroll the screen. Some
13610
         * video adapters wrap around the top of video memory, so the origin can
         * move without bounds. For other adapters screen memory must sometimes be
13611
13612
         * moved to reset the origin. All computations on video memory use character
         * (word) addresses for simplicity and assume there is no wrapping. The
13613
13614
         * assembly support functions translate the word addresses to byte addresses
13615
         * and the scrolling function worries about wrapping.

src/kernel/system.c 14700 /\* This task handles the interface between file system and kernel as well as \* between memory manager and kernel. System services are obtained by sending 14701 \* sys\_task() a message specifying what is needed. To make life easier for 14702 14703 \* MM and FS, a library is provided with routines whose names are of the 14704 \* form sys\_xxx, e.g. sys\_xit sends the SYS\_XIT message to sys\_task. The 14705 \* message types and parameters are: 14706 14707 ÷ SYS\_FORK informs kernel that a process has forked \* SYS\_NEWMAP allows MM to set up a process memory map 14708 \* SYS\_GETMAP allows MM to get a process' memory map 14709 14710 \* SYS\_EXEC sets program counter and stack pointer after EXEC 14711 \* SYS\_XIT informs kernel that a process has exited SYS\_GETSP caller wants to read out some process' stack pointer \* 14712 SYS\_TIMES caller wants to get accounting times for a process \* 14713 SYS\_ABORT MM or FS cannot go on; abort MINIX 14714 \* SYS\_FRESH start with a fresh process image during EXEC (68000 only) 14715 \* SYS\_SENDSIG send a signal to a process (POSIX style) 14716 \* 14717 SYS\_SIGRETURN complete POSIX-style signalling SYS\_KILL cause a signal to be sent via MM SYS\_ENDSIG finish up after SYS\_KILL-type signal \* 14718 ÷ 14719 SYS\_COPY request a block of data to be copied between processes SYS\_VCOPY request a series of data blocks to be copied between procs \* 14720 \* 14721 SYS\_GBOOT copies the boot parameters to a process SYS\_GBOOT returns the next free chunk of physical memory \* 14722 × 14723 SYS\_UMAP \* compute the physical address for a given virtual address 14724 \* SYS\_TRACE request a trace operation 14725 14726 \* Message types and parameters: 14727 14728 14729 \* PROC1 PROC2 PID NEM\_PTR m\_type \* \_\_\_\_\_ 14730 \* | SYS\_FORK | parent | child | pid | | 14731 14732 \* | SYS\_NEWMAP | proc nr | | | map ptr | 14733 14734 \* | SYS\_EXEC | proc nr | traced | new sp | 14735 14736 \* | SYS\_XIT | parent | exitee | | 14737 \* |------14738 \_+----+--\* | SYS\_GETSP | proc nr | 14739 14740 14741 \* | SYS\_TIMES | proc nr | | buf ptr | \* |\_\_\_\_\_+ 14742 \* | SYS\_ABORT | 1 14743 14744 \* | SYS\_FRESH | proc nr | data\_cl | | 14745 14746 × \* | SYS\_GBOOT | proc nr | | | bootptr | 14747 14748 \* | SYS\_GETMAP | proc nr | | | map ptr | 14749 14750 \* \_\_\_\_\_ 14751 \* m\_type m1\_i1 m1\_i2 m1\_i3 m1\_p1 14752 14753 \* \_\_\_\_\_ \* | SYS\_VCOPY | src p | dst p | vec siz | vc addr | 14754

\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\* src/mm/main.c \*\*\*\*\*\*\*\*\*\* /\* This file contains the main program of the memory manager and some related 16600 \* procedures. When MINIX starts up, the kernel runs for a little while, 16601 \* initializing itself and its tasks, and then it runs MM and FS. Both MM 16602 \* and FS initialize themselves as far as they can. FS then makes a call to **1660**3 \* MM, because MM has to wait for FS to acquire a RAM disk. MM asks the 16604 \* kernel for all free memory and starts serving requests. 16605 16606 \* The entry points into this file are: 16607 starts MM running 16608 \* main: reply to a process making an MM system call ¥ reply: 16609 \*/ 16610 16611 #include "mm.h" 16612 #include <minix/callnr.h> 16613 #include <minix/com.h> 16614 #include <signal.h> 16615 16616 #include <fcntl.h> #include <sys/ioctl.h> 16617 #include "mproc.h"

          * This procedure is a little bit tricky. The logical way to load a segment
17504
          * would be to read it block by block and copy each block to the user space
17505
17506
          * one at a time. This is too slow, so we do something dirty here, namely
17507
          * send the user space and virtual address to the file system in the upper
          * 10 bits of the file descriptor, and pass it the user virtual address
17508
17509
          * instead of a MN address. The file system extracts these parameters when
          * gets a read call from the memory manager, which is the only process that
17510
          * is permitted to use this trick. The file system then copies the whole
17511
          * segment directly to user space, bypassing MM completely.

To acquire a block, a routine calls get\_block(), 20100 20101 \* telling which block it wants. The block is then regarded as "in use" \* and has its 'b\_count' field incremented. All the blocks that are not 20102 20103 \* in use are chained together in an LRU list, with 'front' pointing \* to the least recently used block, and 'rear' to the most recently used 20104 \* block. A reverse chain, using the field b\_prev is also maintained. 20105 \* Usage for LRU is measured by the time the put\_block() is done. The second 20106 \* parameter to put\_block() can violate the LRU order and put a block on the 20107 \* front of the list, if it will probably not be needed soon. If a block 20108 20109 \* is modified, the modifying routine must set b\_dirt to DIRTY, so the block 20110 \* will eventually be rewritten to the disk. 20111 \*/ 20112 #include <sys/dir.h> /\* need struct direct \*/ 20113 20114

\_

. . . . .

src/fs/super.h /\* Super block table. The root file system and every mounted file system 20700 \* has an entry here. The entry holds information about the sizes of the bit 20701  $\ast$  maps and inodes. The s\_ninodes field gives the number of inodes available 20702 20703 \* for files and directories, including the root directory. Inode 0 is \* on the disk, but not used. Thus s\_ninodes = 4 means that 5 bits will be \* used in the bit map, bit 0, which is always 1 and not used, and bits 1-420704 20705 \* for files and directories. The disk layout is: 20706 20707 20708 \* # blocks Item ÷ 1 20709 boot block \* 20710 super block 1 20711 \* inode map s\_imap\_blocks zone map s\_zmap\_blocks inodes (s\_ninodes + 20712 \* inodes unused (s\_ninodes + 'inodes per block' - 1)/'inodes per block' \* 20713 \* 20714 whatever is needed to fill out the current zone \* 20715 data zones (s\_zones - s\_firstdatazone) << s\_log\_zone\_size \* 20716 20717 \* A super\_block slot is free if s\_dev == NO\_DEV. 20718 \*/ 20719 20720 20721 EXTERN struct super\_block { /\* # usable inodes on the minor device \*/ 20722 ino\_t s\_ninodes; zone1\_t s\_nzones; 20723 short s\_imap\_blocks; /\* total device size, including bit maps etc \*/ /\* # of blocks used by inode bit map \*/ 20724 /\* # of blocks used by zone bit map \*/ 20725 short s\_zmap\_blocks; zone1\_t s\_firstdatazone;

           /* The best guess for the number of blocks to prefetch: A lot.
23841
            * It is impossible to tell what the device looks like, so we don't even
23842
            * try to guess the geometry, but leave it to the driver.
23843
23844
            * The floppy driver can read a full track with no rotational delay, and it
23845
            * avoids reading partial tracks if it can, so handing it enough buffers to
23846
            * read two tracks is perfect. (Two, because some diskette types have
23847
23848
            * an odd number of sectors per track, so a block may span tracks.)
23849
            * The disk drivers don't try to be smart. With todays disks it is
23850
            * impossible to tell what the real geometry looks like, so it is best to
23851
23852
            * read as much as you can. With luck the caching on the drive allows
            * for a little time to start the next read.
23853
23854
            * The current solution below is a bit of a hack, it just reads blocks from
23855
            * the current file position hoping that more of the file can be found. A
23856
            * better solution must look at the already available zone pointers and
23857
            * indirect blocks (but don't call read_map!).

# INDEX

## A

Absolute path name, 412 Access control list, 448-450 Access matrix, 448 Acknowledgement, 73 ACL (see Access Control List) Adapter, device, 155 Address, virtual, 319 Address space, 15 Advisory file locking, MINIX, 467 Aging, 336-338 Aiken, Howard, 6 ANSI Standard C, 103 ANSI terminal escape sequence, 249 Aperiodic event, 90 Architecture, computer, 3 Assembly language, 8, 9, 22, 53-54 Associative memory, 328 Atomic action, 66 Attribute, file, 408-409 Authentication, 73 user, 442-446 Avoidance of deadlock, 175-179

#### B

Babbage, Charles, 5 Backup, file, 425-426 Bad block handling, 206-207 Banker's algorithm, 175-179 Base register, 313 Batch system, 7-8 Best fit algorithm, 318 Bibliography, alphabetical, 512-517 suggested readings, 507-512 Binary semaphore, 68 Bit map, 316, 458-460 BIOS, 209-210 Bit-map terminal, 237 Block cache, MINIX, 429, 461-463, 474-478 Block device, 154 MINIX, 187-195 Block size, 422-423 Block special file, 20, 405 Boot block, MINIX, 121, 454 Boot monitor, MINIX, 121, 209 Booting MINIX, 96, 120-122

Bootstrap, 96 Bounded buffer problem, 64 Breakpoint, 302 Buffer cache, 429 Busy waiting, 59-63

## C

C-threads, 55 Cache, 430 Call gate, Pentium, 356 Canonical mode, 31-32, 241 Capability, 450-451 Capability list, 450 Catching signals, MINIX, 372 Cats, identification method, 444 Cbreak mode, 31, 247 CDC 6600, 313 Challenge-response authentication, 444 Channel, covert, 451-453 Character device, 154 Character special file, 20, 405 **MINIX, 468** Checkerboarding, 347-348 Child process, 16 Circular wait condition, 168 Classical IPC problem, 75-82 dining philosophers, 75-77 readers and writers, 77-80 sleeping barber, 80-82 Cleaner thread, 433 Click, memory, 363 Client-server operating system, 42-44 Clock, MINIX, 222-235 Clock driver, MINIX, 227-235 Clock hardware, 223-224 Clock interrupt handler, MINIX, 230 Clock page replacement algorithm, 334-335 Clock software, 224-227 Clock tick, 223 Code page, 242 Command interpreter, 16 Compaction, memory, 314 Computer emergency response team, 439 Condition variable, 70 Confinement problem, 452

#### INDEX

Context switch, 84 Contiguous file allocation, 415 Control sequence introducer, 260 Controller, device, 155 Cooked mode, 31, 241 Core dump, MINIX, 373 Core image, 16 Covert channel, 451-453 CP/M, 419-420 Critical region, 58-59 Critical section, 58-59 Crystal oscillator, 223 CTSS, 86-87 Current directory, 412

#### D

Daemon, 95, 165 printer, 57 Data segment, 25-26 Deadlock, 69, 166-179 avoidance, 175-179 banker's algorithm, 175-179 conditions, 168 detection and recover, 172 **MINIX**, 186 modeling, 169-171 ostrich algorithm, 170, 172 prevention, 173-175 resource trajectory, 176-177 safe state, 175-176 state, 175 Deadly embrace (see deadlock) Debugging dumps, MINIX, 295-296 Dekker's algorithm, 61 Demand paging, 338 Descriptor tables, Pentium, 118, 352 Device controller, 155 Device driver, 94, 155, 161-162 MINIX, 181-185 Device independence, 159-160 Device register, 2 Device-independent I/O software, MINIX, 185 Dining philosophers, 75-77 Direct memory access, 157-159 Directory operations, 414-415
Directory, 17, 405, 410-415 CP/M, 419-420 hierarchical, 411-412 implementation, 419-421 MINIX, 463, 465 **MS-DOS**, 420 root, 18 structure, 419-421 UNIX, 420-421 working, 18 Dirty bit, 327 Disk, 200-222 Disk arm scheduling, 203-205 Disk hardware, 200-202 Disk partition, 96 Disk software, 202-208 Disk space management, 422-424 Diskette (see floppy disk) Diskless workstation, 122 Dispatching (see scheduling) Display driver, MINIX, 288-295 Distributed operating system, 12 Distributed shared memory, 343 DMA (see Direct Memory Access) Domain, protection, 447

## E

Earliest deadline first algorithm, 91 ECC (see Error-Correcting Code) Echoing, 242-244 Eckert, J. Presper, 6 EIDE (see Extended Integrated Drive Electronics) Elevator algorithm, 204 Error, I/O, 205-207 Error handling, disk, 205-207 Error-Correcting Code, 155 Escape character, 245 Escape sequence, 291-294 **MINIX**, 249 Exception, Pentium, 136 Exokernel, 42 Extended Integrated Drive Electronics, 210 Extended key prefix, 286 Extended machine, 3-4 External fragmentation, 347-348

#### F

Feature test macro, 112 FIFO (see First-In First-Out page replacement) File, 17-20, 402-410 block special, 20, 405 character special, 20, 405 executable, 405-406 regular, 405 special, 20, 405 File access, 407-408 File allocation contiguous, 415 i-node, 418-419 indexed, 417-418 linked list, 416-417 File attribute, 408-409 File backup, 425-426 File descriptor, 19, 465-467, 481-482 File extension, 403 File locking, MINIX, 467, 482 File naming, 402-403 File operation, 409-410 File position, MINIX, 465 File structure, 404-405 File system, 401-503 bit maps, MINIX, 458-460 consistency, 426-429 directories, 419-421 disk space management, 422-424 implementation, 415-434 log-structured, 432-434 MINIX, 453-503 performance, 429-432 reliability, 424-429 root, 19, 34 File type, 405-407 Filler character, 244 Finger-length identification, 444-445 Fingerprint identification, 445 First fit algorithm, 317 First-in First-out page replacement, 333 First generation computer, 6 Fixed partition, 311-312 Floppy disk driver, MINIX, 220-222 Font. loadable, 264 **MINIX**, 264

FORTRAN, 6-8 Fragmentation, external, 347-348 internal, 342 Free blocks, disk, 423-424 Function key, MINIX, 287

## G

GDT (*see* Global Descriptor Table) GE-645, 11 Generic right, 451 Global descriptor table, Pentium, 124, 143, 352 Global page allocation algorithms, 339-341 Guaranteed scheduling, 89

## Η

Handler, interrupt, 128-137, 161, 180-181 Header files, MINIX, 107-112, 379-382 Header files, POSIX, 102-106 Hertz, 83 Hierarchical directories, 411-412 History of MINIX, 13-15 History of operating systems, 5-15 Hold and wait condition, 168

# I

IBM PC, 14, 107, 122, 126, 132, 156, 191, 194, 201, 202, 208, 313, 357, 360 I-node, 418-419 MINIX, 460-461, 478-480 Intel 8088, 12, 41, 115, 126, 208, 301, 313, 357 I/O, 153-304 clock, 222-235 disk, 200-222 MINIX, 179-304 RAM disk, 195-200 terminal, 235-296

Scheduling (continued) MINIX, 98, 140-142 multiple queues, 86-87 nonpreemptive, 84 policy versus mechanism, 93 preemptive, 83 priority, 85-86 process, 82-92 rate monotonic algorithm, 91 round robin, 84-85 run to completion, 84 shortest job first, 87-89 two-level, 92 XDS 940, 87 Scrolling, terminal, 259 SCSI device, 155 Second chance paging algorithm, 333-334 Second generation computer, 6-8 Security, 434-446 access control list, 448-450 attacks, 439-441 capability, 450-451 design principles, 441-442 flaws, 436-439 physical identification, 444-445 protection mechanisms, 446-453 threats, 434-436 user authentication, 442-446 viruses, 440-441 worm, 438-439 Segment, 345 data, 25-26 Intel versus MINIX stack, 25-26 text, 25-26 Segment descriptor, Pentium, 144, 353 Segmentation, 343-356 implementation, 347-348 **MULTICS**, 348-351 Semaphore, 66-68 binary, 68 Sequential access file, 407 Sequential process (see Process) Server process, 43 Session leader, 272 Shared library, 346 Shared text, MINIX, 359 Shell, 16, 20-21

Shortest job first scheduling, 87-99 Shortest seek first, 204 Signal, 17 **MINIX, 374** SIGNAL primitive, 70 SLEEP primitive, 63-64, 70 Sleep and wakeup, 63-64 Sleeping barber, 80-82 Special file, 20, 405, 468 block, 20 character, 20 **MINIX**, 468 Spooling, 10, 165 Spooling directory, 57, 165 Square-wave mode, 223 SSF (see Shortest Seek First) Stack segment, 25-26 Standard input, 21 Standard output, 21 Starvation, 76 Strict alternation, 60-61 Super-block,, MINIX, 456-458, 480-481 Super-user, 17 Supervisor call, 27 Supervisor mode, 2 Swapping, 313-318 Synchronization, process, 68 Synchronous alarm, MINIX, 228-229, 233 System call, 15, 21-36 directory management, 33-35 file management, 28-33 process management, 22-26 protection, 35-36 signaling, 26-28 time management, 36 (see also MINIX system call) System task, MINIX, 296-304

### T

Tagged architecture, 450 Task, MINIX, 94 synchronous alarm, 228-229, 233 Task state segment, Pentium, 129, 143 TENEX, 437-438

#### 937

#### **INDEX**

Terminal. intelligent, 239 RS-232, 238-239 X. 239-240 Terminal data structure, MINIX, 265-267 Terminal driver support code, 273-282 MINIX, 249-296 Terminal hardware, 235-240 Terminal I/O, MINIX, 235-304 Terminal input, MINIX, 251-256 Terminal output, MINIX, 256-261 Terminal scrolling, hardware, 259 software, 259 Terminal software, 240-249 input, 241-247 output, 247-249 Text segment, 25-26 Third generation computer, 8-11 Thrashing, 338 Threads, 53-56 Tiger team, 439 **Timer**, 222 Timesharing, 10-11 TLB (see Translation Lookaside Buffer) Track-at-a-time caching, 207-208 Translation lookaside buffer, 327-329, 350,351, 355 managed in software, 329-330 Trapdoor, 440 Trojan horse, 438 TSL instruction, 62-63 Two-level scheduling, 92 Two-phase locking, 179

### U

Uid, 17 Uniform naming, 160 Universal coordinated time, 224 UNIX, boot block, 121 deadlock, 172, 186 device driver, 183 directory, 413-414, 420-421 UNIX (continued) error reporting, 56 file system, 402-407, 418, 433 history, 11-13 interprocess communication, 75 process structure, 182 security, 436, 442-443 special file, 163 threads, 56 User authentication, 442-446 User friendliness, 407 User mode, 2 User-level I/O software, MINIX, 185-186 UTC (see Universal Coordinated Time)

### V

Video controller, 236 Video RAM, 235-236 Virtual address, 319 Virtual address space, 319-320 Virtual console, MINIX, 282 Virtual machine, 1-2, 4 Virtual machine monitor, 40-41 Virtual memory, 319-356 demand paging, 338 design issues, 338-343 **MULTICS**, 348-351 page replacement algorithms, 331-338 paging, 319-331 segmentation, 343-356 Virtual memory interface, 343 Virus, 440-441

### W

WAIT primitive, 70 Wakeup, 64 WAKEUP primitive, 63-64, 70 Wakeup waiting bit, 65 Watchdog timer, 226 Winchester disk, 211-212 Window manager, 240 Working directory, 18, 412

#### INDEX

Working set model, 338-339 Worm, 438-439 Worst fit algorithm, 318 Write-through cache, 429 Wsclock page replacement algorithm, 339

# X

X client, 240 X server, 240 X terminal, 239-240 XDS 940, 87

# Z

......

Zombie state, 367-368, 384 Zone, 456-460 Zuse, Konrad, 6
